Hitting times, occupation times, tri-variate laws and the forward Kolmogorov equation for a one-dimensional diffusion with memory

Martin Forde* Andrey Pogudin† Hongzhong Zhang‡

December 19, 2012

Abstract

We extend many of the classical results for standard one-dimensional diffusions to a diffusion process with memory of the form \( dX_t = \sigma(X_t, X_s) dW_t \), where \( X_s = m \wedge \inf_{0 \leq s \leq t} X_s \). In particular, we compute the expected time for \( X \) to leave an interval, classify the boundary behavior at zero and we derive a new occupation time formula for \( X \). We also show that \((X_t, X_s)\) admits a joint density, which can be characterized in terms of two independent tied-down Brownian meanders (or equivalently two independent Bessel-3 bridges). Finally, we show that the joint density satisfies a generalized forward Kolmogorov equation in a weak sense, and we derive a new forward equation for down-and-out call options.

1 Introduction

In [Forde11], we construct a weak solution to the stochastic functional differential equation \( X_t = x + \int_0^t \sigma(X_s, M_s) dW_s \), where \( M_t = \sup_{0 \leq s \leq t} X_s \). Using excursion theory, we then solve the following problem: for a natural class of joint density functions \( \mu(y, b) \), we specify \( \sigma(., .) \), so that \( X \) is a martingale, and the terminal level and supremum of \( X \), when stopped at an independent exponential time \( \xi \), is distributed according to \( \mu \). The proof uses excursion theory for regular diffusions to compute an explicit expression for the Laplace transform of the joint density of the terminal level and the supremum of \( X \) at an independent exponential time, and the joint density satisfies a forward Kolmogorov equation. Integrating twice, we obtain a forward PDE for the up-and-out put option payoff which then allows us to back out \( \sigma \) from the pre-specified joint density. This was inspired by the earlier work of [CHO09] and [Carr09], who show how to construct a one-dimensional diffusion with a given marginal at an independent exponential time.

The main result Theorem 3.6 in [BS12] shows that we can match the joint distribution at each fixed time of various functionals of an Itô process, including the maximum-to-date or the running average of one component of the Itô process. The mimicking process is also a weak solution to stochastic functional differential equation (SFDE) and in the special case when we are mimicking the terminal level and the maximum, the mimicking process is of the form \( X_t = x + \int_0^t \sigma(X_s, M_s, s) dW_s \).

In this article, we consider the case when the diffusion coefficient \( \sigma(., .) \) depends only on \( X \) and its running minimum, and we assume \( X \) is strictly positive, and \( \sigma(x, m) \) is continuous with \( 0 < \sigma(x, m) < \infty \) for \( x > 0, m \geq 0, m \leq x \), and that \( \sigma(0, 0) = 0 \). The purpose of the article is to extend many of the standard well known results for one-dimensional diffusions to the case when \( \sigma \) also depends on the running minimum (as opposed to solving one problem in particular), and we give financial motivation/applications where appropriate.

In Theorem 2.2 we prove weak existence and uniqueness in law for \( dX_t = \sigma(X_t, X_s) dW_t \) by extending the usual time-change argument for one-dimensional diffusions. In Proposition 3.1, we compute the expected length of time to hit either of two barriers for \( X \), as a simple application of Itô’s lemma and the optional sampling theorem. We then examine the non-trivial question of when the hitting time \( H_0 \) to zero is finite or not (almost surely); specifically, in Theorem 4.1 we show that for \( \varepsilon \in (0, m) \)

\[
\mathbb{P}(H_0 < \infty) = 0 \quad \text{if and only if} \quad \int_0^\varepsilon \int_0^u \hat{m}(u, v) dv du = \infty
\]
where \( \tilde{m}(x, m) = \frac{1}{\sigma(x, m)^2} \). For the case when \( \tilde{m} \) is independent of \( m \), this reduces to the well known condition that \( \mathbb{P}(H_0 < \infty) = 0 \) if and only if \( \int_0^\infty \tilde{m}(v) dv = \infty \) (see e.g. Theorem 51.2 (i) in [RW87]). We then formulate an extension of the classical occupation time formula for the new \( X \) process (Theorem 5.2).

In Theorem 6.1, by adapting the argument in [Rog85] and using Girsanov’s theorem and conditioning on the terminal value and the minimum of \( X \), we prove the existence of the joint density \( p_t(x, m) \) for \( X \) and its minimum. We then further characterize this joint density in terms of two independent back-to-back Brownian meander bridges, which we can further represented in terms of two independent Bessel-3 bridges using standard results in e.g. Bertoin et al.[BCP99],[BCP03] and [Imh84]. Finally in section 8, we show that \( X \) is a weak solution to a forward Kolmogorov equation, and we also derive a new forward equation for down-and-out call options.

## 2 A one-dimensional diffusion with memory

In this section, we construct a weak solution to the stochastic functional differential equation

\[
X_t = x + \int_0^t \sigma(X_s, X_s) dW_s
\]

where \( X_t = m \land \inf_{0 \leq s \leq t} X_s \) and \( W \) is standard Brownian motion, and we show that the solution \( X \) is unique in law. The \( m \) parameter allows us to include the possibility that \( X \) has accrued a previous historical minimum \( m \) which may be less than \( X_0 = x \).

We make the following assumptions on \( \sigma \) throughout:

**Assumption 2.1**

(i) \( \sigma \) is continuous, and strictly positive away from \((0, 0)\)

(ii) \( \sigma(0, 0) = 0 \)

(iii) \( \lim_{x \to 0} \frac{x}{\sigma(x, x)^2} = 0 \)

We let \( H_b \) denote the first hitting time to \( b \):

\[
H_b = \inf\{s : X_s = b\}
\]

and define \( \tilde{m}(u, v) = \frac{1}{\sigma(u, v)^2} \).

### 2.1 Weak existence and uniqueness in law

**Theorem 2.2** (2) has a non-exploding weak solution for \( t < H_\delta \) which is unique in law, where \( 0 < \delta \leq m \leq x \).

**Proof.**

- (Existence). Let \((B_t, P_x)\) denote a standard Brownian motion defined on some \((\Omega, \mathcal{F}, (\mathcal{F}_t))\) with \( B_0 = x > 0 \), \( B_t = \inf_{0 \leq s \leq t} B_s \), and assume that \( \mathcal{F} \) satisfies the usual conditions\(^2\). Let \( T_t \) denote the a.s. strictly increasing process

\[
T_t = \int_0^t \tilde{m}(B_s, m \land B_s) ds
\]

for \( t < \tau_\delta \) for some \( \delta > 0 \), where

\[
\tau_a = \inf\{s : B_s = a\}.
\]

Let \( A_t = \inf\{s : T_s = t\} \) denote the inverse of \( T_t \), and set

\[
X_t = B_{A_t}.
\]

Then we have

\[
\int_0^{A_t} \sigma^2(B_s, m \land B_s) dT_s = \int_0^{A_t} ds = A_t.
\]

\(^2\)i.e. \( \mathcal{F}_t \) is right continuous and \( \mathcal{F}_0 \) contains all \( \mathcal{F} \) sets of measure zero.
If we make the change of variables 
\[ u = T_s \] so 
\[ du = dT_s = \tilde{m}(B_s, m \wedge B_s) ds \]
then we can re-write the integral on the left as 
\[ A_t = \int_0^t \sigma^2(X_u, X_u) du \]
a.s., where we have used a pathwise application of the Lebesgue-Stieltjes change of variable formula. Thus 
\[ \langle X \rangle_t = A_t \] a.s. Then by Theorem 3.4.2 in [KS91], there exists a Brownian motion \( W \) on some extended probability space such that (2) is satisfied.

\[ X_t = B_t \] a.s. Then by Theorem 3.4.2 in [KS91], there exists a Brownian motion \( W \) on some extended probability space such that (2) is satisfied.

- (Uniqueness in law). We proceed along similar lines to Lemma V.28.7 in [RW87]. By Theorem IV.34.11 in [RW87], if \( X \) satisfies (2), then
\[ B_t = X_{T_t} \] (6)
is standard Brownian motion, where \( T_t = \inf\{ s : \langle X \rangle_s = t \} \), so
\[ \int_0^{T_t} \sigma(X_s, X_s) ds = t. \]
Differentiating with respect to \( t \) we obtain
\[ \sigma(X_{T_t}, X_{T_t})^2 T'_t = 1 = \sigma(B_t, m \wedge B_t)^2 T'_t, \]
\[ dT_t = \tilde{m}(B_t, m \wedge B_t) dt. \]
Hence
\[ \langle X \rangle_t = \inf\{ u : \int_0^u \tilde{m}(B_s, m \wedge B_s) ds = t \}. \]
Thus \( X \) may be described explicitly in terms of the Brownian motion \( B \), so the law of \( X \) is uniquely determined.

Finally, stopping \( X \) at \( H_\delta \) means we are only running \( B \) until time \( \tau_\delta \), and \( \tau_\delta < \infty \) a.s., so \( (X_{t \wedge H_\delta}) \) cannot explode to infinity a.s. ■

From here on we work on the canonical sample space \( \Omega = C([0, \infty), \mathbb{R}^+) \) with the canonical process \( X_t(\omega) = \omega(t) \) \( (\omega \in \Omega, t \in [0, \infty)) \) and its canonical filtration \( \mathcal{F}_t = \sigma(X_s; s \leq t) \). Let \( \mathbb{P}_{x,m} \) denote the law on \( (\Omega, \mathcal{B}(\Omega)) \) induced by a weak solution to (2) (which is unique by Theorem 2.2).

**Remark 2.1** If \( \sigma \equiv \sigma(x, m, t) \) is time-dependent, we can still obtain weak existence and uniqueness if the solution to the ordinary differential equation \( dT_t = \tilde{m}(B_t, m \wedge B_t) dt \) is uniquely determined a.s. This will be the case if \( \tilde{m} \) is Lipschitz in the third argument.\(^3\)

We refer the reader to [Mao97] and [Moh84] for existence and uniqueness results for general Stochastic functional differential equations.

### 2.2 Application in financial modelling

We can consider a time-homogenous local volatility model with memory for a forward price process \( (F_t)_{t \geq 0} \) which satisfies
\[ dF_t = F_t \mu dt + F_t \sigma(F_t, E_t) dW_t \]
under the physical measure \( \mathbb{P} \). This has the desirable feature of being a complete model, so under the unique risk neutral measure \( \mathbb{Q} \), \( F_t \) will satisfy \( dF_t = F_t \sigma(F_t, E_t) dW_t \), i.e. a diffusion-type process of the form in (2).

\(^3\)We thank Gerard Brunick for pointing this out.
3 The expected time to leave an interval

The following proposition computes a closed-form expression for the expectation of the exit time from an interval, using Itô’s lemma and a simple application of the optional sampling theorem. This proposition will be needed in the next section where we classify the boundary behaviour of $X$ at zero. The proof is similar to that used for a regular diffusion in section 5.5, part C in [KS91] and page 197 in [KT81].

**Proposition 3.1** We have the following expression for the expected time for $X$ to leave the interval $(a, b)$:

$$h(x, m) = \mathbb{E}_{x, m}(H_a \land H_b)$$

$$= 2 \int_m^x (u - x)\tilde{m}(u, m)du + \frac{2(x - m)}{b - m} \int_m^b (b - u)\tilde{m}(u, m)du + 2(b - x)C(m) < \infty,$$

(7)

for $0 < a \leq m \leq x \leq b < \infty$, where $C(m) = \int_a^b \int_{a}^{u \land m} \frac{b - u}{(b - v)^2} \tilde{m}(u, v)dvdu$.

**Proof.** We can easily verify that $h(x, m)$ satisfies

$$\tilde{m}(x, m) = \frac{1}{2} h_{xx}, \quad h(m, m) = 0,$$

(8)

with endpoint condition $h(a, a) = h(b, m) = 0$ for all $a \leq m < b$.

Now let $\tau = H_a \land H_b$. Then by Itô’s lemma, we have

$$h(X_{t \land \tau}, X_{s \land \tau}) - h(x, m) = \int_0^{t \land \tau} h_x(X_s, X_s)dX_s + \frac{1}{2} \int_0^{t \land \tau} h_{xx}(X_s, X_s)\sigma^2(X_s, X_s)ds$$

$$+ \int_0^{t \land \tau} h_m(X_s, X_s)dX_s$$

$$= \int_0^{t \land \tau} h_x(X_s, X_s)dX_s + \frac{1}{2} \int_0^{t \land \tau} h_{xx}(X_s, X_s)\sigma^2(X_s, X_s)ds$$

using the second equation in (8) and the fact that $dX_s = 0$ if $X_t \neq X_s$. $h_x(u, v)$ and $\sigma(u, v)$ are bounded for $0 < a \leq v \leq u \leq b$, so taking expectations and applying the optional sampling theorem, and using the first equation in (8), we have

$$\mathbb{E}_{x, m}(h(X_{t \land \tau}, X_{s \land \tau})) = h(x, m) - \mathbb{E}_{x, m}(t \land \tau).$$

(9)

$\tilde{m}(u, v) \leq K$ for $0 < a \leq v \leq u \leq b$ for some constant $K > 0$, so we have

$$h(x, m) = \mathbb{E}_{x, m}(H_a \land H_b)$$

$$= 2 \int_m^x (u - x)\tilde{m}(u, m)du + \frac{2(x - m)}{b - m} \int_m^b (b - u)\tilde{m}(u, m)du + 2(b - x)C(m)$$

$$\leq 2K \left[ \int_m^x (x - u)du + \int_m^b (b - u)du + (b - x) \int_a^b \int_u^{u \land m} \frac{b - u}{(b - v)^2}dvdu \right] < \infty.$$

Thus $h(\cdot, \cdot)$ is continuous and bounded, so letting $t \to \infty$ in (9) and applying the dominated convergence theorem on the left hand side and the monotone convergence theorem on the right hand side, and using that $h(a, a) = h(b, m) = 0$, we obtain (7). 

4 Absorption at zero

**Theorem 4.1** Let $\varepsilon \in (0, m)$. Then we have the following boundary behaviour for $X$:

$$\mathbb{P}_{x, m}(H_0 < \infty) = 0 \quad \text{if and only if} \quad \int_0^\varepsilon \int_0^\varepsilon \tilde{m}(u, v)dvdu = \infty.$$
Thus we have established that

\[ P_x(H_0 < \infty) = 0 \] if and only if \[ \int_{0^+} v\tilde{m}(v)dv = \infty \]

(see e.g. Theorem 51.2 (i) in [RW87]).

**Proof.** (of Theorem 4.1). Setting \( a = 0 \) in (7), we have

\[ C(m) = \int_0^b \int_a^{u \land m} \frac{b-u}{(b-v)^2} \tilde{m}(u,v)dvdu \]  \hspace{1cm} \text{(10)}

and \( E_{x,m}(H_0 \land H_b) < \infty \) if and only if \( C(m) < \infty \), because \( \tilde{m}(0,0) = \infty \) and \( \tilde{m} < \infty \) elsewhere, all the upper limits of integration are finite and \( \frac{1}{b-v} \) will not explode because the upper range of \( v \) is \( m < b \). Noting that \( \frac{b-u}{(b-v)^2} \to 1 \) as \( u,v \searrow 0 \) and replacing the upper limits of integration by \( \varepsilon \in (0,m) \), we see that

\[ E_{x,m}(H_0 \land H_b) < \infty \] if and only if \[ C\varepsilon(m) = \int_0^\varepsilon \int_a^{u \land m} \tilde{m}(u,v)dvdu < \infty . \]  \hspace{1cm} \text{(11)}

Thus we have established that \( E_{x,m}(H_0 \land H_b) < \infty \) if and only if \( \int_0^\varepsilon \int_a^u \tilde{m}(u,v)dvdu < \infty \). We now need to verify that \( P_{x,m}(H_0 < \infty) = 0 \) if and only if \( \int_0^\varepsilon \int_a^u \tilde{m}(u,v)dvdu = \infty \).

- First assume that \( \int_0^\varepsilon \int_a^u \tilde{m}(u,v)dvdu < \infty \). Then \( E_{x,m}(H_0 \land H_b) < \infty \), so \( H_0 \land H_b < \infty \) a.s and \( P_{x,m}(H_0 = H_b = 0) = 0 \). But from the construction of \( X \) via a time-changed Brownian motion \( B \) in (5), we know that \( P_x(\tau_0 < \tau_b) > 0 \) where \( \tau_a \) is the first hitting time of \( B \) to \( a \) as defined in (4), hence \( P_{x,m}(H_0 \leq H_b) > 0 \), \( P_{x,m}(H_0 < H_b) > 0 \) and

\[ P_{x,m}(H_0 < \infty) \geq P_{x,m}(H_0 < H_b < \infty) > 0 . \]

- Conversely, assume that \( P_{x,m}(H_0 < \infty) > 0 \). For this part, we proceed as in the proof of Lemma 6.2 in [KT81]. Then there exists a \( t > 0 \) for which

\[ P_{x,m}(H_0 < t) = \alpha > 0 . \]

Every path starting at \( x \) and reaching zero prior to time \( t \) visits every intervening state \( \xi \in (0,x) \). Thus we have

\[ 0 \leq \alpha \leq P_{x,m}(H_0 - H_\xi < t) = P_{\xi,\xi \land m}(H_0 < t) \leq P_{\xi,\xi \land m}(H_x \land H_0 < t) \]

for \( 0 < \xi \leq x \). It follows that

\[ \sup_{\xi \in (0,x)} P_{\xi,\xi \land m}(H_x \land H_0 \geq t) \leq 1 - \alpha < 1 , \]

and by induction, we find that

\[ \sup_{\xi \in (0,x)} P_{\xi,\xi \land m}(H_x \land H_0 \geq nt) \leq (1 - \alpha)^n < 1 . \]

We can re-write this as

\[ P_{\xi,\xi \land m}(H_x \land H_0 \geq a) \leq (1 - \alpha)^{a/t} \leq (1 - \alpha)^{a/t-1} . \]  \hspace{1cm} \text{(12)}

We now recall the general result on e.g. page 79 in [Will91]: for any non negative random variable \( Y \) we have

\[ E(Y) = \int_{[0,\infty)} P(Y \geq y)dy . \]

Thus \( E(Y) < \infty \) if and only if \( \int_{(R,\infty)} P(Y \geq y)dy < \infty \) for any \( R > 0 \). Thus setting \( Y = H_x \land H_0 \) we have

\[ E_{\xi,\xi \land m}(H_x \land H_0) < \infty \]

if and only if \( \int_{(R,\infty)} P_{\xi,\xi \land m}(H_x \land H_0 \geq a)da < \infty . \)
5 The occupation time formula

Remark 4.2 For a stock price model of the form in (7), Theorem 4.1 allows us to compute whether or not the stock will default by hitting zero or not in a finite time under the risk neutral measure $Q$, which is relevant for the pricing of so-called credit default swaps, which pay 1 dollar at maturity $T$ if the stock defaults before $T$.

5.1 Almost sure convergence for an approximating sequence of diffusion processes

Recall that $\tau_b = \inf\{s : B_s = b\}$. Set $0 < b \leq m \leq x$, and $\tilde{m}_n(u, v) = \tilde{m}(u, \frac{1}{n}[vn])$ for $n \geq 1$, so that $\tilde{m}_n(u, v)$ is piecewise constant in $v$, and define the process

$$X^n_t = B^n_{A^n_t}$$

(13)

where $A^n_t$ is the strictly increasing continuous inverse of

$$T^n_t = \int_0^{\tau_m \land t} \tilde{m}(B_s, m)ds + \int_{\tau_m \land t}^t \tilde{m}_n(B_s, B_s)ds$$

for $0 \leq t < \tau_0$. Note that $X_t = X^n_t$ for $0 \leq t \leq H_m$, because the $m$ dependence in $\sigma$ is “frozen” until $X$ sets a new minimum below $m$.

Proposition 5.1 Let $H^n_b = \inf\{s : X^n_s = b\}$ and $H_b = \inf\{s : X_s = b\}$ as before for $b \in (0, m)$. Then $H^n_b \to H_b$ a.s. and $X_{t \land H_b} - X^n_{t \land H^n_b} \to 0$ a.s.

Proof. Without loss of generality, we assume that $x = m$, otherwise we just start from time $H_m$ instead of time zero. From the time-change construction in the proof of Theorem 2.2, we know that $B_t = X^n_{T_t}$ and $B_{\tau_0} = X^n_{H_b}$ so we have

$$H_b = \int_0^{\tau_0} \tilde{m}(B_s, B_s)ds$$

and similarly

$$H^n_b = \int_0^{\tau_0} \tilde{m}_n(B_s, B_s)ds.$$

Using the uniform continuity of $\tilde{m}(u, v)$ on $\{(u, v) : \frac{1}{R} \leq u \leq v \leq R\}$ for any $R \in (1, \infty)$, and the fact that $\sup_{0 \leq s \leq \tau_b} B_s(\omega) < \infty$ a.s., we know that for any $\varepsilon > 0$ there exists a $N = N(\omega)$ such that for all $n > N(\omega)$ we have

$$|H_b - H^n_b| = \left| \int_0^{\tau_0} [\tilde{m}(B_s, B_s) - \tilde{m}_n(B_s, B_s)]ds \right|$$

$$= \left| \int_0^{\tau_0} [\tilde{m}(B_s, B_s) - \tilde{m}(B_s, \frac{1}{n}[n B_s])]ds \right| \leq \varepsilon \tau_0.$$
and \( \tau_b < \infty \) \( P_x \) a.s., so \( H_b \rightarrow H^n_b \) a.s. Now, let \( \bar{m}_{\min}(\omega) = \inf_{0 \leq s \leq \tau_b} \bar{m}(B_s(\omega), B_s(\omega)) < \infty \) a.s. By the definition of the inverse processes \( A_t \) and \( A^n_t \), we have

\[
\begin{align*}
t \wedge H_b &= \int_0^{A_t \wedge \tau_b} \bar{m}(B_s, B_s)ds \geq (A_t \wedge \tau_b) \bar{m}_{\min}(\omega), \\
t \wedge H^n_b &= \int_0^{A^n_t \wedge \tau_b} \bar{m}_n(B_s, B_s)ds.
\end{align*}
\]

Remark 5.1

See Appendix A.

Proof. Let \( (\tilde{l}^x_t) \) denote the local time process for \( B \) in (5) at the level \( x \).

Theorem 5.2 Let \( x = m \), \( 0 < \delta < x \) and \( f : \mathbb{R}^2 \rightarrow \mathbb{R}^+ \) be a bounded, continuous function. Then we have the occupation time formula

\[
\int_{H_b \wedge t}^H f(X_s, X_s)ds = \sum_{\delta < m \leq x} \int_m^\infty f(x, m) \bar{m}(x, m) \bar{l}^x_{t \wedge \tau_b} dx \quad \text{a.s.}
\]

(17)

where \( \bar{l}^x_{t \wedge \tau_b} = \int_0^t 1_{B_s \in [m]} dl_s^x = l^x_{t \wedge \tau_b} - l^x_{t \wedge \tau_b} \geq 0 \) is the local time that \( B \) spends at \( x \) when the minimum is exactly \( m \), and the sum is taken over the (a.s. countable) \( m \)-values where \( B \) makes a non-zero upward excursion from a minimum at \( m \).

Proof. See Appendix A. \[ \Box \]

Remark 5.1 Theorem 5.2 is clearly more involved than the standard occupation time formula. However, it can be used to show that \( \int_0^\epsilon \int_0^\epsilon \bar{m}(u, v)dvdu < \infty \) implies that

\[ \mathbb{P}_{x, m}(H_0 < \infty) = 1, \]

which combined with Theorem 4.1 shows that \( \mathbb{P}(H_0 < \infty) \) is either one or zero depending on the finiteness of \( \int_0^\epsilon \int_0^\epsilon \bar{m}(u, v)dvdu \) (we defer the details for future work).
6 Transition densities

6.1 Existence of a joint transition density for \((X_t, X'_t)\)

**Theorem 6.1** Define the function
\[
\tilde{\sigma}(y, y) = e^{-y} \sigma(e^y, e^y)
\]
for all \(y \geq y\), and assume that
- \(\tilde{\sigma}(y, y)\) possesses bounded continuous partial derivatives of all orders up to and including 2;
- \(\int_0^\infty \int_0^u \tilde{\mu}(u, v) dv du = \infty\) so \(P(H_0 < \infty) = 0\).

Then under \(P_{x,x}\), \((X_t, X'_t)\) defined in (2) admits a joint density \(p_t(x', x')\).

**Remark 6.1** Note that under \(P_{x,m}\) with \(x > m\), there is a non-zero probability that \(X_t = m \land \inf_{0 \leq s \leq t} X_s = m\), i.e. the law of \(X_t\) has an atom at \(m\).

**Proof.** Let \(Y_t := \log X_t\), \(Y'_t := \log X'_t\), which are well defined because \(X\) cannot hit zero in finite time a.s. We notice that \(Y_0 = Y'_0\). Using Itô’s lemma we have
\[
dY_t = \tilde{\sigma}(Y_t, Y'_t) dW_t - \frac{1}{2} \tilde{\sigma}^2(Y_t, Y'_t) dt.
\]

Let us define
\[
\rho_t = \inf\{u \leq t : X_u = X_t\}.
\]
Because the log function is monotonically increasing, we have that \(\rho_t = \inf\{u \leq t : Y_u = Y'_t\}\). We now make a transformation of \(Y\) to a process with diffusion coefficient equal to one. To this end, we first define
\[
\eta(y) = \int_{y_0}^y \frac{du}{\tilde{\sigma}(u, u)},
\]
\[
\beta(y, y') = \eta(y) + \int_y^{y'} \frac{du}{\tilde{\sigma}(u, y')},
\]
and consider the new processes \(Z_t := \beta(Y_t, Y'_t)\) and \(Z'_t := \inf_{s \leq t} Z_s\), then \(Z_0 = \beta(Y_0, Y'_0) = 0\). Notice that for all \(t\),
\[
Z_t = \beta(Y_t, Y'_t) = \eta(Y'_t) + \int_{Y_t}^{Y'_t} \frac{du}{\tilde{\sigma}(u, Y'_t)} \geq \eta(Y'_t),
\]
and from this we see that
\[
Z_t = \inf_{s \leq t} Z_s \geq \eta(Y'_t). \tag{18}
\]
It turns out that we have equality in (18), since at time \(\rho_t \leq t\) we have \(Y_{\rho_t} = Y'_t\). Using the monotonicity of \(\eta(\cdot), \beta(\cdot, \cdot)\), we have
\[
Y_t = \eta^{-1}(Z_t), \tag{19}
Y'_t = \beta^{-1}(Z_t, \eta^{-1}(Z_t)),
\]
\[
\rho_t = \inf\{u \leq t : Z_u = Z_t\}, \tag{20}
\]
where \(\beta^{-1}(\cdot, y)\) is the inverse of function \(\beta(\cdot, \cdot)\).

Since \(\beta\) is at least \(C^2\), using Itô’s lemma we obtain that
\[
dZ_t = dW_t - \frac{1}{2} \left[\tilde{\sigma}(Y_t, Y'_t) + \tilde{\sigma}_y(Y_t, Y'_t)\right] dt = dW_t + b(Z_t, Z'_t) dt.
\]
where \( b(z, \zeta) = -\frac{1}{2} \{ \bar{\sigma}(\beta^{-1}(z, \eta^{-1}(\zeta)), \eta^{-1}(\zeta)) + \bar{\sigma}(\beta^{-1}(z, \eta^{-1}(\zeta)), \eta^{-1}(\zeta)) \} \). In light of (19) and (20), it suffices to show that \((Z_t, \bar{Z}_t)\) has a density function.

We now mimic the proof of [Rog85], and consider a new measure \( \tilde{\mathbb{P}} \) defined by

\[
\frac{d\tilde{\mathbb{P}}}{d\mathbb{P}}|_{\mathcal{F}_t} = \exp\{ \int_0^t b(Z_s, \bar{Z}_s) dZ_s - \frac{1}{2} \int_0^t b^2(Z_s, \bar{Z}_s) ds \}.
\]

By Girsanov’s theorem, the process \((Z_t)\) is a standard Brownian motion under measure \( \tilde{\mathbb{P}} \). Now define the \( C^2 \) function \( h(z, \zeta) = \int_z^\zeta b(u, \zeta) du + \int_0^x b(u, u) du \).

Using Itô’s lemma we have

\[
dh(Z_t, \bar{Z}_t) = b(Z_t, \bar{Z}_t) dZ_t + \frac{1}{2} b_z(Z_t, \bar{Z}_t) dt,
\]

from which we obtain that (notice that \( h(Z_0, \bar{Z}_0) = h(0, 0) = 0)\)

\[
h(Z_t, \bar{Z}_t) - \frac{1}{2} \int_0^t b_z(Z_s, \bar{Z}_s) ds = \int_0^t b(Z_s, \bar{Z}_s) dZ_s.
\]

Now for any bounded bi-variate continuous function \( f \), we have

\[
\mathbb{E}(f(Z_t, \bar{Z}_t)) = \tilde{\mathbb{E}}(f(Z_t, \bar{Z}_t)) e^{\frac{1}{2} \int_0^t g(Z_s, \bar{Z}_s) ds}
\]

where \( g = b^2 + b_z \). Conditioning on \((Z_t, \bar{Z}_t) = (z, \zeta)\) for \( z > \zeta, \zeta < 0 \), we obtain

\[
\mathbb{E}(f(Z_t, \bar{Z}_t)) = \int_{-\infty}^\infty \int_{-\infty}^{\infty} f(z, \zeta) \phi_t(z, \zeta) e^{h(z, \zeta)} \tilde{\mathbb{E}}(e^{\frac{1}{2} \int_0^t g(Z_s, \bar{Z}_s) ds} | Z_t = z, \bar{Z}_t = \zeta) dz d\zeta
\]

where \( \phi_t(z, \zeta) \) is the joint density of the standard Brownian motion \((Z_t)\) and its minimum \( \bar{Z}_t \). Thus, the pair \((Z_t, \bar{Z}_t)\) has a joint density

\[
p_t^{Z, \bar{Z}}(z, \zeta) = \phi_t(z, \zeta) e^{h(z, \zeta)} \tilde{\mathbb{E}}(e^{\frac{1}{2} \int_0^t g(Z_s, \bar{Z}_s) ds} | Z_t = z, \bar{Z}_t = \zeta).
\] (21)

It follows that the pair \((Y_t, \bar{Y}_t) = (\log X_t, \log \bar{X}_t)\) has joint density

\[
p_t^{Y, \bar{Y}}(y, \bar{y}) = p_t^{Z, \bar{Z}}(\beta(y, \bar{y}), \eta(\bar{y})) \frac{\partial \beta}{\partial y} \frac{\partial \eta}{\partial \bar{y}} = \frac{p_t^{Z, \bar{Z}}(\beta(y, \bar{y}), \eta(\bar{y}))}{\bar{\sigma}(y, \bar{y})}. \]

(22)

\[\Box\]

**Remark 6.2** For a stock price model of the form in (7), the existence of a semi-closed form density for \((X_t, \bar{X}_t)\) as proved above allows us to price general barrier option contracts with payoffs of the form \( \varphi(X_t, \bar{X}_t) \) for a measurable function \( \varphi \).

### 6.2 Characterizing the joint density in terms of Bessel-3 bridges

From (21) and (22), it is seen that the regularity of the joint density of \( p_t^{Y, \bar{Y}}(y, \bar{y}) \) depends on that of \( h \) in (21) and the following function \( \psi_t \):

\[
\psi_t(z, \zeta) = \tilde{\mathbb{E}}(e^{\frac{1}{2} \int_0^t g(Z_s, \bar{Z}_s) ds} | Z_t = z, \bar{Z}_t = \zeta).
\] (23)

The function \( \psi_t \) depends on the law of a standard Brownian motion \((Z_s)_{0 \leq s \leq t}\) given \( Z_t \), and \( \bar{Z}_t \). To this end, let us condition on \((Z_t, \bar{Z}_t, \rho_t) = (z, \zeta, u)\). \((Z_t, \bar{Z}_t, \rho_t)\) has a smooth density given by

\[
\chi_t(z, \zeta, u) = 2f(z, u) f(\zeta, t - u) e^{-\frac{\zeta(z - u)}{\pi u^2 (t - u)^2}} -\frac{\zeta(z - u)}{\pi u^2 (t - u)^2} e^{-\frac{\zeta(z - u)}{\pi u^2 (t - u)^2}}
\]
where \( f(y,t) = \frac{|y|}{\sqrt{2\pi t^3}} e^{-y^2/2t} \) is the hitting time density from 0 to \( y \) for standard Brownian motion (see e.g. [Imh84]). Moreover, given \((Z_t, Z_r, \rho_t) = (z, \tilde{z}, u)\), the path fragments

\[
(Z_{u-s} - \tilde{z})_{0 \leq s \leq u} \quad \text{and} \quad (Z_{u+s} - \tilde{z})_{0 \leq s \leq t-u}
\]

are two independent Brownian meanders of lengths \( u \) and \( t-u \), starting at 0 and conditioned to end at \(-\tilde{z} > 0\) and \( z - \tilde{z} > 0\) respectively (see e.g. [BCP99]). A Brownian meander of length \( s \) is defined as the re-scaled portion of a Brownian path following the last passage time at zero \( G_1 = \sup\{s \leq 1 : B_s = 0\} \):

\[
B^\text{me}_{u} = \sqrt{s \frac{1 - G_1}{G_1}} |B_{G_1 + s}(1 - G_1)| \quad (0 \leq u \leq s)
\]

(see page 63 in [BorSal02]). It is known that the law of a Brownian meander of length \( s \) is identical to that of a standard Brownian motion starting at zero and conditioned to be positive for \( t \in [0, s] \) (see e.g. [DIM77]). Moreover, the tied-down Brownian meander, i.e. the Brownian meander conditioned so that \( B^\text{me}_{u} = x > 0 \) has the same law as a 3-dimensional Bessel bridge \( R^\text{br} \) with \( R^\text{br}_0 = 0 \) and \( R^\text{br}_t = x \) (see e.g. [Imh84], [BCP03]).

Hence, the path fragments \((Z_{u-s} - \tilde{z})_{0 \leq s \leq u}\) and \((Z_{u+s} - \tilde{z})_{0 \leq s \leq t-u}\) can be identified with two independent Bessel-3 bridges, starting at 0, ending at \(-\tilde{z} > 0\) and \( z - \tilde{z} > 0\) respectively (see [BCP99], [Will74]). Thus, as in [Pau87], we have

\[
\kappa_t(z, \tilde{z}, u) = \mathbb{E}(e^{-\frac{1}{2} \int_0^t g(Z_s, Z_r) ds} | Z_t = z, Z_r = \tilde{z}, \rho_t = u) \cdot \mathbb{E}(e^{-\frac{1}{2} \int_0^t g(\tilde{Z}_s, \tilde{Z}_r) ds} | Z_t = z, Z_r = \tilde{z}, \rho_t = u)
\]

\[
= \mathbb{E}(e^{-\frac{1}{2} \int_0^t g(Z_s, Z_r) ds} | Z_t = z, Z_r = \tilde{z}, \rho_t = u) \cdot \mathbb{E}(e^{-\frac{1}{2} \int_0^t g(\tilde{Z}_s, \tilde{Z}_r) ds} | Z_t = \tilde{z}, Z_r = \tilde{z}, \rho_t = u)
\]

and we can re-write the last expectation in terms of the two aforementioned independent Bessel 3 bridges if we wish. It follows that

\[
\psi_t(z, \tilde{z}) = \mathbb{E}(e^{-\frac{1}{2} \int_0^t g(Z_s, Z_r) ds} | Z_t = z, Z_r = \tilde{z})
\]

\[
= \int_0^t \kappa_t(z, \tilde{z}, u) \mathbb{P}(\rho_t \in du | Z_t = z, Z_r = \tilde{z}) du
\]

\[
= \int_0^t \kappa_t(z, \tilde{z}, u) \chi_t(z, \tilde{z}, u) \phi_t(z, \tilde{z}) du.
\]

7 A generalized forward Kolmogorov equation

In this section we assume that \( m = x = x_0 \) so \( X_0 = X_x = x_0 > 0 \) and we use \( \mathbb{E} \) as shorthand for \( \mathbb{E}_{x_0,x_0} \). We further assume that \( \int_0^s \int_u^s \tilde{m}(u, v) dv du = \infty \) so \( \mathbb{P}_{x_0}(H_0 < \infty) = 0 \), i.e. \( X \) cannot hit zero a.s. and for simplicity we assume that \( \sigma \) is bounded \(^5\). Let \( O = \{(x,y) \in \mathbb{R}^+ \times \mathbb{R}^+ : x \geq y\} \) denote the support of \((X_t, X_x)\).

**Theorem 7.1** \((X_t, X_x)\) satisfies the following forward equation

\[
\frac{\partial}{\partial t} \mathbb{E}(f(X_t, X_x, t)) = \mathbb{E}(f_t(X_t, X_x, t) + \frac{1}{2} f_{xx}(X_t, X_x, t) \sigma(X_t, X_x)^2)
\]

for all test functions \( f \in C^2_b(O \times \mathbb{R}^+) \) satisfying \( f_y(y,y,t) = 0 \).

**Proof.** See Appendix B. \( \blacksquare \)

**Remark 7.1** If \( f \in C^\infty_c(O \times \mathbb{R}^+) \), re-writing (24) in terms of integrals and integrating from \( t = 0 \) to \( \infty \) and using that \( f(t, X_t, X_x) = 0 \) a.s. for \( t \) sufficiently large, we see that \( p(t, dx, dy) = \mathbb{P}(X_t \in dx, X_x \in dy) \) satisfies

\[
\int_0^\infty \int_O (f_t + \frac{1}{2} \sigma(x,y)^2 f_{xx}) p(t, dx, dy) dt = 0
\]

\(^5\)We can easily relax this assumption by working in log space as in the previous section, but in the interests of clarity and succinctness, we do not do this here.

\(^6\)\( C^\infty_c \) means smooth with compact support.
Remark 7.2 If \( p(t, dx, dy) \) admits a density so that \( p(t, dx, dy) = p(t, x,y) dx dy \) and \( p \) and \( \sigma \) are twice continuously differentiable in \( x \) and \( p \) is once differentiable in \( t \), then integrating (25) by parts we have
\[
\int_{t=0}^{\infty} \int f(x,y,t) [-\partial_t p + \partial^2_{xx}(\frac{1}{2} \sigma(x,y)^2 p)] dx dy dt \ = \ 0
\]
and thus (by the arbitraryness of \( f \)), \( p(t,x,y) \) is a classical solution to the family of forward Kolmogorov equations:
\[
\partial_t p \ = \ \partial^2_{xx}(\frac{1}{2} \sigma(x,y)^2 p) \quad (x \neq y)
\]
for all \( y \leq x \) (see page 252 in [RW87], Theorem 3.2.6 in [SV79] and [Fig08] for similar results and weak formulations for a standard diffusion process).

7.1 A forward equation for down-and-out call options

Proposition 7.2 Assume \( k > 0 \), \( 0 < b < x_0 \). Then
\[
\mathbb{E}(X_t - k)^+1_{x > b} - (X_0 - k)^+ = \frac{1}{2} \mathbb{E}(L^k_{t \wedge H_b}) - (b - k)^+ \mathbb{P}(X_t \leq b),
\]
where \( L^k_t \) is the semimartingale local time of \( X \) at \( a \) as defined in e.g. Theorem 3.7.1 in [KS91] and \( H_b = \inf \{ s : X_s = y \} \), subject to the following boundary condition at \( x = y \):
\[
\mathbb{E}(X_t - b)^+1_{x > b} = \mathbb{E}(X_t - b)1_{x > b} = x_0 - b.
\]

Remark 7.3 (26) is a forward equation for a down-and-out call option on \( X_t \) with strike \( x \), which knocks out if \( X \) hits \( y \) before time \( t \). Specifically (assuming zero interest rates and dividends) the left hand side is the fair price of the down-and-out call, and the \( \mathbb{P}(X_t \leq y) \) term on the right-hand side is the price of a One-Touch option on \( X_t \) which pays 1 if \( X \) hits \( y \) before time \( t \).

Remark 7.4 (27) is the same condition that appears in [Rog12], and if \( X_t \) has no atom at \( y \), we can differentiate (27) with respect to \( y \) to obtain the condition in Theorem 3.1 in [Rog93].

Remark 7.5 The financial interpretation of (27) is the well known result that (for zero dividends and interest rates) we can semi-statically hedge a down-and-out call option with barrier \( b \) equal to the strike \( k \), by buying one unit of stock and holding \( -b \) dollars, and unwinding the position if/when the barrier is struck (see e.g. Appendix A in [Der95]).

Proof. (of Proposition 7.2). From the generalized Itô formula given in e.g. Theorem 3.7.1 in [KS91], we obtain
\[
d(X_t - k)^+ = 1_{x > k} dX_t + \frac{1}{2} dL^k_t.
\]
Integrating from time zero to \( t \wedge H_b \) we obtain
\[
(X_{t \wedge H_b} - k)^+ - (X_0 - k)^+ = (X_t - k)^+1_{H_b > t} + (b - k)^+1_{H_b \leq t} - (X_0 - k)^+ = \int_0^{t \wedge H_b} 1_{x > k} dX_s + \frac{1}{2} L^k_{t \wedge H_b}.
\]
Taking expectations and simplifying, we obtain (26).

To obtain the boundary condition in (27), we use the optional sampling theorem for the bounded stopping time \( t \wedge H_b \) to obtain
\[
\mathbb{E}(X_{t \wedge H_b}) = x_0 = \mathbb{E}(X_t 1_{x > b}) + \mathbb{E}(X_{H_b} 1_{H_b \leq t}) = \mathbb{E}(X_t 1_{X > b}) + b \mathbb{E}(X_t \leq b) = \mathbb{E}((X_t - b)1_{X > b}) + b \mathbb{E}(1_{X \leq b}) = \mathbb{E}((X_t - b)1_{X > b}) + b,
\]
where the last equality follows because \( X_t > b \) on \( \{ X_t > b \} \), i.e. if \( X \) does not hit \( b \) before time \( t \).
References

Using the standard occupation time formula for $t \in [H_{n+1}, H_n]$ for each $k = 0 \ldots [x_0 n] - 1$. For the left hand integral, from Proposition 5.1, we know that where $\mathcal{F} = (X_n^a, X_n^b)$ defined in (13) is just a regular one-dimensional diffusion process for $t \in [H_{n+1}, H_n]$ for each $k$ (see Theorem 49.1 in [RW87]), we have

$$\int_{H_{n+1} \land t}^{H_n \land t} f_n(x_n^a, x_n^b) dx = \int_0^{\infty} f(x, \frac{k}{n}) \tilde{m}(x, \frac{k}{n}) \mathcal{F}_x, m_{\tau_b} d\mathcal{F}_n$$

$$= \int_0^{\infty} \sum_{\frac{k}{n} < m \leq \frac{k+1}{n}} f_n(x, m) \tilde{m}_n(x, m) \mathcal{F}_x, m_{\tau_b} d\mathcal{F}_n$$

where $f_n(x, m) = f(x, \frac{1}{n}[nm])$, $l_x^{(a,b)} = \int_0^t \mathbb{1}_{B_n \in (a,b)} d\mathcal{F}_n$ is the local time that $B$ has accrued at $x$ at time $t$ while $B \in (a, b)$, and we are summing over (a.s. countable) $m$-values in $(\frac{k}{n}, \frac{k+1}{n})$ for which there is a non-zero upward excursion from a minimum at $m$.

Summing over $k$ until time $t \land H_n$ and taking the finite sum inside the integral on the right hand side, we obtain

$$\int_0^{t \land H_n} f(X_n^a, X_n^b) ds = \int_0^t f(X_n^a, X_n^b) 1_{s < H_n} ds$$

$$= \sum_{k=0}^{[x_0 n] - 1} \int_0^{\infty} \sum_{\frac{k}{n} < m \leq \frac{k+1}{n}} f_n(x, m) \tilde{m}_n(x, m) \mathcal{F}_x, m_{\tau_b} ds$$

$$= \int_0^{\infty} \sum_{\frac{k}{n} < m \leq \frac{k+1}{n}} f_n(x, m) \tilde{m}_n(x, m) \mathcal{F}_x, m_{\tau_b} ds$$

$$= \int_0^{\sup_{0 \leq s \leq \tau_x} B_x} \left[ \sum_{\delta < m \leq x} f_n(x, m) \tilde{m}_n(x, m) \mathcal{F}_x, m_{\tau_b} \right] ds$$

(A-1)

For the left hand integral, from Proposition 5.1, we know that $H_n \rightarrow H_\delta$ a.s. and $X_{t \land H_n} \rightarrow X_{t \land H_\delta}$ a.s., so $f(X_n^a, X_n^b) 1_{s < H_\delta} \rightarrow f(X_s, X_s) 1_{s < H_\delta}$ Lebesgue a.e. on $[0, t]$, a.s. Thus, by the dominated convergence theorem, we have $\int_0^t 1_{s < H_\delta} f(X_n^a, X_n^b) ds \rightarrow \int_0^t 1_{s < H_\delta} f(X_s, X_s) ds = \int_0^{t \land H_\delta} f(X_s, X_s) ds$ a.s.

For the integrand on the right hand side, we have the upper bound

$$\sum_{\delta < m \leq x} f_n(x, m)\tilde{m}_n(x, m) \mathcal{F}_x, m_{\tau_b} \leq \tilde{m}_{\max}(\delta, \omega) \mathcal{F}_x, m_{\tau_b} < \infty \text{ a.s.}$$

where $\tilde{m}_{\max}(\delta, \omega) = \sup_{0 \leq s \leq \tau_\delta} \tilde{m}(B_s, B_s) < \infty$ a.s. Thus, letting $n \rightarrow \infty$ on both sides of (A-1), and applying the dominated convergence theorem on the right hand side as well, and then applying Fubini’s theorem, we obtain (17).
B Proof of Theorem 7.1

Let \( \sigma_t = \sigma(X_t, X_t) \). \( X_t \) and \( X_t \) are continuous semimartingales, so we can apply Itô’s formula to the test function \( f \in C^{2,1,1}_b(O \times \mathbb{R}^+) \):

\[
df(X_t, X_t, t) = f_x(X_t, X_t, t)dX_t + \frac{1}{2} f_{xx}(X_t, X_t, t) \sigma_t^2 dt + f_y(X_t, X_t, t)dX_t,
\]

where we have used that \( X_t = X_t \) on the growth set of \( X_t \) in the final term (recall that \( \psi_y(y, y, t) = 0 \)). Integrating we obtain

\[
f(X_t, X_t, t) - f(x_0, x_0, 0) = \int_0^t f_x(X_s, X_s, s)dX_s + \int_0^t \frac{1}{2} f_{xx}(X_s, X_s, s)\sigma_s^2 ds.
\]

Taking expectations, and applying Fubini’s theorem yields

\[
\mathbb{E}(f(X_t, X_t, t)) - f(x_0, x_0, 0) = \int_0^t \frac{1}{2} \mathbb{E}(f_{xx}(X_s, X_s, s)\sigma_s^2) ds.
\]

\[\text{(B-2)}\]

\( X_t \) and \( X_t \) are continuous in \( t \) a.s. and \( \sigma(.,.) \) is continuous, so \( \sigma_t = \sigma(X_t, X_t, t) \) is also continuous in \( t \) a.s. Moreover, \( f \in C^{2,1,1}_b \) so \( f_{xx}(., .) \) is bounded and continuous, and \( f_{xx}(X_u, X_u, u)\sigma_u^2 \to f_{xx}(X_s, X_s, s)\sigma_s^2 \) a.s. as \( u \to s \). \( \sigma \) is also bounded, thus from the dominated convergence theorem we have

\[
\lim_{u \to s} \mathbb{E}(f_{xx}(X_u, X_u, u)\sigma_u^2) = \mathbb{E}(f_{xx}(X_s, X_s, s)\sigma_s^2),
\]

so the integrand \( \mathbb{E}(f_{xx}(X_s, X_s, s)\sigma_s^2) \) in (B-2) is continuous in \( s \) for all \( s \). Thus using the fundamental theorem of calculus, we can differentiate (B-2) everywhere with respect to \( t \) to get

\[
\frac{\partial}{\partial t} \mathbb{E}(f(X_t, X_t, t)) = \mathbb{E}(f_t(X_t, X_t, t) + \frac{1}{2} f_{xx}(X_t, X_t, t)\sigma(X_t, X_t)^2).
\]

\[\text{(B-3)}\]

---

Footnote: By growth set, we mean the support of the random measure induced by the process \( Y \) on \([0, T]\), i.e. the complement of the largest open set of zero measure.
