Windows Extension	Macintosh File Type	What's in the File
.pct	PICT	Macintosh PICT file
.bmp	BMPp	Windows bitmap file
.*	????	Any type file

In addition to the standard Windows extensions listed above, Igor also recognizes files with the “.bwav” and “.away” extensions. These are recognized as equivalent to “.ibw” and “.itx” for backward compatibility with old versions of Igor.

Igor also maps the following extensions to the associated file type. However, the file types listed in this table are fictitious. They are not file types that are really used on Macintosh but they still work, for example, in the Open operation.

Windows Extension	Fictitious Macintosh File Type	What's in the File
.ihf	IHLP	Igor help file (WMT0 files on Macintosh)
.ipf	IPRC	Procedure file (TEXT files on Macintosh)
.dat	.DAT	Data file
.csv	.CSV	Comma-separated file
.emf	.EMF	Enhanced metafile
.wmf	.WMF	Windows metafile
.bmp	.BMP	Bitmap file
.png	.PNG	PNG file
.htm	HTML	HTML file

Igor maps all extensions not listed above to the file type '????' which signifies “unknown file type”. This includes files that have no extension.

The `TextFile` function will recognize only files of type TEXT. On Windows, a file must have the “.txt” extension to be of type TEXT.

The `IndexedFile` function requires that you supply a file type or a file extension as a parameter. Thus, the following commands will print the name of the first file in the Igor directory whose type is TEXT (extension is “.txt”):

```
Print IndexedFile(Igor, 0, "TEXT")
Print IndexedFile(Igor, 0, ".txt")
```

This will print the name of the second file of any type:

```
Print IndexedFile(Igor, 1, "????")
```

Points Versus Pixels

Most measurements of length in Igor are in terms of points. A point is roughly 1/72 of an inch.

A pixel is the area taken up by the smallest displayable dot on an output device such as a CRT or a printer. The physical width and height of a pixel depends on the device. CRTs typically display 60 to 120 pixels per inch (commonly called “dots per inch” or DPI). Printers typically display 150 to 2400 DPI.

The physical size of a screen pixel can vary from one CRT to another. The size of a pixel on a given CRT can often be adjusted by the user by twiddling knobs on the back of the CRT or using buttons on the front panel. Because of this, software programs don't know about or worry about the physical size of a pixel but instead deal with an assumed or “logical” size.

On the Macintosh, the logical width and height of a screen pixel is always 1/72 of an inch, which equates to a logical resolution of 72 DPI. The user can change the physical resolution but not the logical resolution. If a monitor's physical resolution is close to 72 DPI, there will be a pretty good match between the logical and physical sizes. On such monitors, if you make a graph 5 inches (360 points) wide, it will appear roughly 5 inches wide.

On Windows, the default logical width and height of a screen pixel is 1/96 of an inch which equates to a logical resolution of 96 DPI. The user can change both the physical resolution and the logical resolution using the Windows Display Properties control panel. It is common to have a significant discrepancy between the logical and physical sizes. In other words, if you make a graph 5 inches (360 points) wide, it may appear 6 or 7 inches wide. If you want the physical size of an object on the screen to match its logical size, you need to find an appropriate combination of physical and logical resolutions.

Window Position Coordinates

With one exception, Igor stores and interprets window position coordinates in units of points. For example the command

```
Display/W=(5, 42, 405, 242)
```

specifies the left, top, right, and bottom coordinates of the window in points relative to a reference point which is, roughly speaking, the top/left corner of the menu bar. Other Igor operations that use window position coordinates in points include Edit, Layout, NewNotebook, PlayMovie and MoveWindow.

The exception is the control panel window. To make it easier to create control panels that look the same on Macintosh and Windows, the NewPanel operation interprets its /W coordinates as pixels and operations that create or modify controls also interpret coordinates as pixels.

Most users do not need to worry about the exact meaning of these coordinates. However, for the benefit of programmers, here is a discussion of how Igor interprets them.

On the Macintosh, the reference point, (0, 0), is the top/left corner of the menu bar on the main screen. On Windows, the reference point is 20 points above the bottom/left corner of the main Igor menu bar. This difference is designed so that a particular set of coordinates will produce approximately the same effect on both platforms, so that experiments and procedures can be transported from one platform to another.

The coordinates specify the location of the content region, in Macintosh terminology, or the client area, in Windows terminology, of the window. They do not specify the location of the window frame or border.

On the Macintosh, a point is always interpreted to be one pixel.

On Windows, the correspondence between a point and a pixel can be controlled by the user, as described under **Points Versus Pixels** on page III-389. Since Igor stores window positions in units of points, if the user changes the number of pixels per point, the size of Igor windows in pixels will change. The exception is that control panels will not change because Igor interprets their coordinates as pixels.

Notebook Issues

On Macintosh, Igor stores the settings (font, size, style, etc.) for a plain text file in the file's resource fork. The data fork contains just the plain text. On Windows, text files have no resource fork. Therefore there is no way for Igor to store settings for a plain text file on Windows. When you open a plain text notebook or an experiment containing a plain text notebook on Windows, Igor uses preferences to set the notebook's text format. Thus, text format changes that you make to a plain text notebook are lost on Windows unless you capture them as your preferred text format.

PNG Pictures in Notebooks

If you want to display notebook pictures on both platforms, they must be in one of these cross-platform formats: PNG, JPEG, TIFF. Although EPS is a cross-platform format, the EPS screen preview on Macintosh is PICT, which is not cross-platform.

If you have pictures in PICT or EMF format and you want them to be viewable on both platforms, you should convert them to PNG. Igor uses PNGs for Igor help files which need to be platform-independent.

There are two ways to create a PNG picture in an Igor notebook. You can load it from a file using Misc→Pictures and then place it in a notebook or you can convert a picture that you have pasted into a notebook using Notebook→Special→Convert to PNG.

The Convert to PNG command in the Notebook→Special menu converts the selected picture or pictures into PNG. It skips selected pictures that are already PNG or that are foreign (not native to the platform on which you are running). You can determine the type of a picture in a notebook by clicking in it and looking at the notebook status line. If you select just one picture and do the conversion, Igor will let you undo it. However, if you select anything other than a single picture, the conversion will not be undoable. You can interrupt a conversion by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*) and holding until Igor stops the conversion.

When you create a PNG file from within Igor, you can create it at screen resolution or at higher resolution. If you want crisp screen display when viewed at 100 percent magnification, use screen resolution when you create the PNG file. If you want better quality when viewed at higher magnifications and when printed, use higher than screen resolution when you create the PNG file. Using higher resolution requires a lot of memory during the conversion and when the picture is displayed but usually does not require excessive disk space when saved because PNGs are compressed. Once you have created a PNG file, you can load it into another program or into Igor using Misc→Pictures.

The next three paragraphs explain how Igor treats screen resolution PNGs differently from high resolution PNGs. You can skip this if you don't care about the technical details.

Normally, Igor stretches pictures if necessary to preserve the logical size of the pictures at different screen resolutions. However, PNG, being a bitmap type of picture, looks best when displayed without stretching. Therefore, Igor treats PNGs in notebooks specially. If the PNG was created at screen resolution, Igor displays the PNG without stretching. This gives a crisp, undistorted display when viewed at 100 percent magnification, but the physical size of the picture is not preserved. This is usually what you want for screen dumps and for graphics intended mostly for viewing on screen at 100% magnification as opposed to printing or viewing on screen at higher magnifications.

For example, suppose you create a 5 inch by 4 inch graph on the Macintosh and export that graph as a screen-resolution PNG. You paste the PNG into a notebook. On the Macintosh, the screen resolution is 72 dpi, so the PNG will be 72 dpi. Thus, the dimensions of the PNG in pixels is 360 by 288 (5*72 by 4*72). If you save the notebook and open it on Windows, Igor notices that the PNG is screen resolution and will therefore displays it using 360 by 288 pixels. This means that Igor does not need to stretch the PNG so it displays crisply. However, because Windows screen resolution is typically 96 dpi, the logical size of the PNG on Windows will be smaller than 5 inches by 4 inches by a factor of 72/96.

If instead of creating a screen-resolution PNG, you create a high-resolution PNG, Igor will stretch the PNG by a factor of 96/72 on Windows. This makes the logical size of the PNG the same on both platforms but it will be somewhat distorted on Windows because of the stretching.

Dashed Lines

The dashed lines built into Igor can be edited with the Dashed Lines dialog (Misc menu).

You can edit one dashed line pattern at a time. The example shows the last dashed line (number 17) being edited. You can select another line with the Dashed Line pop-up menu. Dashed line 0 (the solid line) cannot be edited. If you need to create a custom dashed line pattern, we recommend that you modify the high numbered dashed lines, leaving the low number ones in their default state. This ensures that the low numbered patterns will be the same for everyone.

Dashed lines are described by pairs of dash and gap lengths. You can add or remove pairs with the More Pairs and Fewer Pairs buttons. The lengths can be adjusted by entering dash and gap values, or by dragging the dash (filled boxes) and gap (hollow boxes) handles.

You can also change dashed lines with the **SetDashPattern** operation (see page V-489).

Dashed lines are stored with the experiment, so each experiment may have different dashed lines. You can capture the current dashed lines as the preferred dashed lines for new experiments.

The Color Environment

Igor has a main color palette that contains colors that you can use for traces in graphs, text, axes, backgrounds and so on. The main color palette appears as a pop-up menu in a number of dialogs, such as the Modify Trace Appearance dialog. This section discusses this palette.

Igor also has color tables and color index waves you can select among when displaying contour plots and images. These are discussed in Chapter II-14, **Contour Plots**, and Chapter II-15, **Image Plots**.

You can select from colors presented in a color palette.

You can use the Other button to select colors that are not in the palette. As you use Igor, colors are added to the palette in the Recent Colors area.

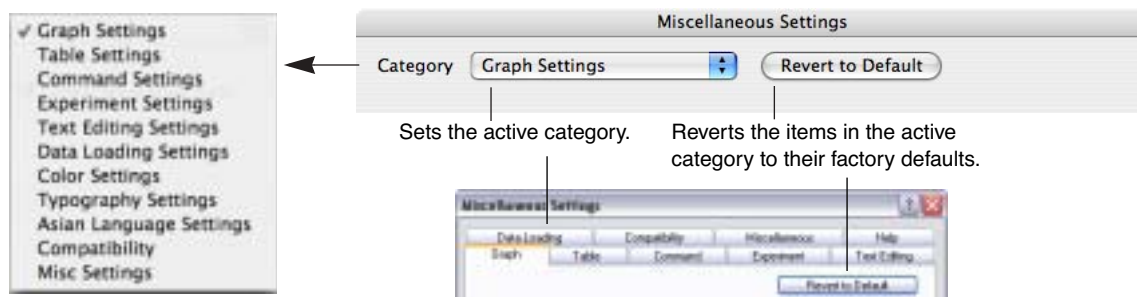

On Macintosh only, the recent colors are remembered by Igor when it quits and restored when it restarts if you have selected the "Save and restore color palette's recent colors" checkbox in the Miscellaneous Settings dialog's Color Settings category.

If you run your monitor in 256 (8 bit) color mode, Igor has to make compromises in an attempt to provide reasonably accurate colors while still allowing other programs to display reasonably accurate colors. It is recommended that you set your monitor to the thousands of colors (16 bit) or millions of colors (32 bit) mode.

Miscellaneous Settings

You can customize some aspects of how Igor works using the Miscellaneous Settings dialog. The miscellaneous settings are grouped into categories.

Changes to miscellaneous settings take effect immediately when you click the Save Settings button. They affect the current experiment as well as new and old (reopened) experiments.

Graph Settings

The Repeat Wave Style Prefs in Graphs checkbox affects the way wave trace style preferences are applied when waves are appended to a graph. The factory default is selected. See **Graph Preferences** on page II-278.

When the Enable “Fling” Mode checkbox is checked, dragging in a graph with Option or Alt pressed and the mouse down will “fling” (scroll) the graph contents in the direction of the drag. To stop the motion, click in the graph while keeping the mouse still.

Table Settings

The Repeat Column Style Prefs in Tables checkbox affects the way column style preferences are applied when columns are appended to a table. The factory default is selected. See **Table Preferences** on page II-210.

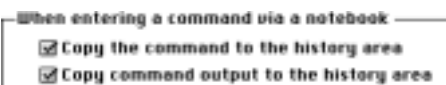

Command Settings

The Limit Command History Text checkbox determines the number of lines of history text that Igor will retain in a given experiment. The factory default is deselected (no limit). Limiting history can save space on disk but more importantly can reduce clutter in the history area of the command window. It can also reduce the time it takes to open and save an experiment.

If you select the Limit Command History Text checkbox and enter the number of lines of history that you want to keep, Igor will automatically trim the history to that number of lines when you save the experiment. In addition, when Igor adds text to the history, it checks the number of lines. If it exceeds the requested maximum by 500 lines, Igor trims the history at that time, rather than waiting until you save the experiment. This is done so that if, for example, you run an experiment overnight, the history will not grow without bound.

You can enter and execute commands in a notebook as well as from the command window.

These settings let you determine whether Igor stores commands and output in the history area as well as in the notebook. See **Notebooks as Worksheets** on page III-4 for general information on using a notebook as a worksheet.

Experiment Settings

The Saved Experiment Format pop-up menu controls the way Igor experiments are saved. You can override this choice in the Save Experiment dialog. The choice here merely presets the dialog's Packed checkbox. The factory default is Packed. See **Saving Experiments** on page II-24 for details.

Files and Folder Packed

Unlike most spreadsheet and graphing programs, data can exist in Igor without being visible in a table. The “Make a new table for new experiments” checkbox controls whether you will get a new empty table when you choose New Experiment from the File menu. The default state is selected. This is convenient if you generally start working by entering data manually. If you do not enter data manually, you may find it more convenient to turn this checkbox off and create a table only when you need one.

Data Loading Settings

The Loaded Igor Binary Data pop-up menu determines how Igor handles the loading of Igor Binary waves from disk files. This menu addresses a subtlety that caught many early Igor users off guard. Igor Binary data can be shared between experiments. Old versions of Igor defaulted to *sharing* loaded Igor Binary data, but many users thought that a loaded wave was another isolated *copy* of the data.

Share (do not copy) Always Copy to Home Ask if Copy to Home

Use this pop-up menu to choose how Igor handles Igor Binary waves loaded from a disk file. Copy to Home makes an isolated copy of the wave in the experiment's home folder. If the experiment is saved in packed format, the isolated copy is stored in the experiment's packed file, which contains all the things usually stored in a home folder.

If you choose Ask if Copy to Home, you always get a chance to change your mind with a dialog. If you choose Share or Always Copy to Home, you can change your mind only if you use the Load Waves dialog; the Load Igor Binary dialog uses the setting you make here without asking for confirmation. The factory default is Ask if Copy to Home. See **Sharing Versus Copying Igor Binary Files** on page II-147 for details.

Default Data Precision presets the numerical precision checkboxes in the Make Waves and Load Waves dialogs. The factory default is Double. Note that this affects only the dialogs; if you use commands entered manually on the command line the default is single precision. See **Number Type and Precision** on page II-68 for details.

Single Double

Color Settings (Macintosh)

Selecting the “Save and restore color palette's recent colors” checkbox restores the recent colors that were in the color palette when Igor quit. If deselected, Igor starts up with no recent colors. The factory default is deselected (don't restore colors).

The Color Palette menu sets the accuracy with which colors are drawn when you run in 256 color (8 bit) mode. It is recommended that you set your monitor to the thousands of colors (16 bit) or millions of colors (32 bit) mode.

Typography Settings (Macintosh)

This section discusses the way Igor draws text in graphs and page layouts.

By default, Igor handles text in graphs and page layouts in a method designed to provide good readability of text on the screen and also good fidelity between text on the screen and text on the printed page. If you are satisfied with Igor's default performance in these regards, then you don't need to read the following material.

There is a trade-off to be made between readability of text on the screen and fidelity of text between the screen and the printed page. Unfortunately, there is no way to have maximum readability and maximum fidelity at the same time. You can control this trade-off via three checkboxes in the Typography section of the Miscellaneous Settings dialog.

Achieving text fidelity requires certain actions on the part of Igor, Apple's QuickDraw graphics software and the printer driver. Lack of fidelity stems from the fact that screen resolution is low while printer resolution is high. Because of roundoff and other effects, the width of a string on the screen does not necessarily

match the width of that same string when printed. The reasons for this are too complex to explain here. Apple's technical note TN-TEXT TE 21 gives some idea of the issues involved.

The “Use fractional character widths”, “Use outline fonts”, and “Use precision text sizes” checkboxes control aspects of how Igor draws text in graphs and page layouts.

The default and recommended state for the “Use fractional character widths” and “Use precision text sizes” checkboxes is on. Turning “Use outline fonts” on makes text in some fonts, such as Geneva and Monaco, difficult to read on screen. Because of this, the default state for this checkbox is off.

When the “Use fractional character widths” checkbox is on, Igor uses Apple's QuickDraw to keep track of the position of characters using higher precision arithmetic. This slightly distorts text on the screen but improves the fidelity with printed text.

When the “Use outline fonts” checkbox is on, Igor uses Apple's QuickDraw to create the outline versions of fonts (TrueType or PostScript) instead of the bitmap versions. This also distorts text on the screen but improves the fidelity with printed text. The “Use outline fonts” checkbox makes a big difference with some fonts, such as Geneva, Monaco and Courier, and makes little difference with other fonts, such as Helvetica, Palatino and Times. Results on your computer may be different because you have different versions of these fonts, different system software or different printer driver software.

The “Use precision text sizes” checkbox to do a more precise calculation when converting screen text sizes to printer text sizes. The only reason to turn this feature off is to make this version of Igor behave like Igor Pro 2.0.

If all three checkboxes are deselected, you will get the same behavior as in Igor Pro 2.0. This produces good looking text but with less emphasis on text fidelity. Use it only for backward compatibility.

If you change the state of the “Use fractional character widths” or “Use outline fonts”, Igor will automatically update all open graphs and page layouts. This is not needed if you change just the Use precision text sizes checkbox because this does not affect what is drawn on the screen.

Asian Language Settings (*Macintosh*)

The Font / Keyboard Synchronization settings control whether or not Igor will automatically match the keyboard input method and the active font. Synchronization applies to text documents and to tables.

The “Sync keyboard to font in text windows” checkbox determines whether Igor will set the keyboard script when you choose a font or click in a section of text in a particular font. If this is selected and you click in Asian text, Igor will activate the Asian keyboard method. If you click in Roman text, Igor will deactivate the Asian keyboard method. Igor chooses the Asian keyboard method if the font is Asian and the text at the insertion point in the document is Asian. Thus, if you mix Asian and Roman characters all in an Asian font, Igor will activate the appropriate keyboard for the text at the insertion point.

The “Sync font to keyboard in text windows checkbox” determines whether Igor will change the font automatically if you manually change the keyboard input method. If this is selected and you change the keyboard input method to Asian, Igor will automatically switch to an Asian font. If you change the keyboard input method to Roman, Igor will automatically switch to a Roman font. You may prefer to enter Roman text in an Asian font. If so then you should deselect this checkbox and manually change the font as needed.

The “Sync keyboard to font in table text columns” checkbox determines whether Igor will set the keyboard script when you click in a text column in a table. If this is on and you click in a column whose font is Asian, Igor will activate the Asian keyboard methods. If you click in a column whose font is Roman, Igor will deactivate the Asian keyboard method.

The “Sync keyboard to font in table numeric columns” checkbox determines whether Igor will set the keyboard script when you click in a numeric column in a table. We recommend that you leave this deselected and use Roman numbers in numeric columns because Igor currently does not understand non-Roman numbers.

The “Use Asian Font for Dialog Text Areas” checkbox controls the font that Igor will use for certain special dialog text entry areas, such as the text entry area in the Add Annotation and Browse Waves dialogs. Because they require advanced capabilities such as scrolling and undo, these areas are not standard Macintosh text boxes but rather are implemented using WaveMetrics’ special routines. Normally these areas use the Geneva font. This prevents Asian users from entering Asian characters. When the Use Asian Font for Dialog Text Areas checkbox is selected, Igor will use an Asian font for these areas.

Compatibility Settings

The Native GUI Appearance for Controls checkbox sets the default user-defined control appearance. Deselect it to use the Igor Pro 5 user-defined control appearance.

The Native GUI Font Sizes for Controls checkbox will set the default font sizes for user-defined controls to closely match the text size to what the operating system uses for controls. Deselect it to use the generally smaller font sizes of Igor Pro 5.

Deselecting the Floating Tool and Info Palettes checkbox sets the Tool and Info palette locations to be internal to the associated window, as in Igor Pro 5, rather than using the default floating palettes. This is a simpler way to set this behavior than `SetIgorOption useNewToolPalette=0` or `SetIgorOption useNewInfoPanel=0`. The setting will affect all new ShowInfo and ShowTools commands; current Info and Tool palette locations are not affected.

Misc Settings

The “Use short menu bar names” checkbox, when selected, shortened some menu names. If deselected, it uses long menu names. The factory default is deselected (long names). You may want to select this if you are running on a small screen or have many user-defined menus.

The “Maximum pop-up menu items” setting limits the number of menu items in some pop-up menus, such as the pop-up menus of waves, variables, string variables, and the Current Object pop-up menu in the Object Status dialog. Choosing a small value (the minimum is 50) prevents excessive start-up time for dialogs at the expense of listing all the items in the pop-up menus. We recommend that you set this to several hundred. Igor displays the spinning hand watch cursor when building large pop-up menus. You can type Command-period (*Macintosh*) or Ctrl+Break (*Windows*) to stop building the pop-up menu. Some dialogs have multiple pop-up menus that cause the cursor to reappear; you can type Command-period (*Macintosh*) or Ctrl+Break (*Windows*) again.

“Preferred units of length” controls the default units used in the Modify Graph, Print Graph, Export Graph, and Save Graphics dialogs. It does not affect page layouts or notebooks. These have their own preference settings for units (use the Capture Layout Preferences and Capture Notebook Preferences dialogs). This also does not affect the control dialogs (for adding buttons, checkboxes, etc.). These dialogs always use points as the default unit of measure.

points inches cm

“Operations that overwrite or delete folders” determines what to do when a MoveFolder or CopyFolder command is about to overwrite a folder on disk or when a DeleteFolder command is about to delete a folder on disk.

The factory default setting is “Display dialog to ask user for permission”. This means that Igor will ask for permission each time one of these operations is about to overwrite or delete a folder on disk. This setting is intended to reduce the chance of accidental or malicious deletion of files.

The other choices are “Always give permission” and “Always deny permission”. “Always give permission” grants blanket permission to overwrite or delete folders. Choosing this increases the risk of accidental or malicious deletion of files so you should exercise caution.

(*Macintosh*) “Use Command-H for Find Selection (instead of Command-Control-H)” controls the keyboard shortcut for the “Find Selection” menu item in the Edit menu. The Find Selection keyboard shortcut defaults to Command-Control-H, allowing Command-H to hide Igor on Mac OS X, per Apple’s recommendation. The Igor Pro 4 keyboard shortcut of Command-H can be restored by selecting this checkbox. When selected, hiding Igor on Mac OS X requires selecting “Hide Igor” with the mouse.

Keyboard Navigation affects the behavior of keys such as Page Down, Page Up, End and Home.

Use Macintosh Conventions
Use Windows Conventions

The Windows Menu Shows popup menu determines how target windows are identified in the submenus of the Windows menu. By default, just the window’s title is displayed. You can choose to display the title and /or the name using this setting.

Help Settings (*Windows*)

These are controls governing the display of tool tips, the little windows that pop up automatically when you point at buttons and icons.

Object Names

Every Igor object has a name which you give to the object when you create it or which Igor automatically assigns. You use an object’s name to refer to it in dialogs, from commands and from Igor procedures. The named objects are:

Waves	Data folders	Variables (numeric and string)
Windows	Symbolic paths	Pictures
Annotations	Controls	Rulers

In Igor Pro, the rules for naming waves and data folders are not as strict as the rules for naming all other objects, including string and numeric variables, which are required to have standard names. These sections describe the standard and liberal naming rules.

Standard Object Names

Here are the rules for standard object names:

- May be 1 to 31 characters in length.
- Must start with an alphabetic character (A-Z or a-z).
- May include alphabetic or numeric characters or the underscore character.
- Must not conflict with other names (of operations, functions, etc.).

All names in Igor are case insensitive. wave0 and WAVE0 refer to the same wave.

Characters other than letters and numbers, including spaces and periods, are not allowed. We put this restriction on names so that Igor can identify them unambiguously in commands, including waveform arithmetic expressions.

Historical Note: Prior to Igor Pro 3.0, wave names were limited to 18 characters.

Liberal Object Names

The rules for liberal names are the same as for standard names except that almost any character can be used in a liberal name. Liberal name rules are allowed for waves and data folders only.

If you are willing to expend extra effort when you use liberal names in commands and waveform arithmetic expressions, you can use wave and data folder names containing almost any character. If you create liberal names then you will need to enclose the names in single (not curly) quotation marks whenever they are used in commands or waveform arithmetic expressions. This is necessary to identify where the name ends. Liberal names have the same rules as standard names except you may use any character except control characters and the following:

" ' : ;

Here is an example of the creation and use of liberal names:

```
Make 'wave 0';      // 'wave 0' is a liberal name
'wave 0' = p
Display 'wave 0'
```

Note: Providing for liberal names requires extra effort and testing on the part of Igor programmers (see **Programming with Liberal Names** on page IV-121) so you may occasionally experience problems using liberal names with user-defined procedures.

Name Spaces

When you refer to an object by name, in a user function for example, each object must be referenced unambiguously. In general, an object must have a unique name so. Sometimes the object type can be inferred from the context, in which case the name can be the same as objects of other types. Objects whose names can be the same are said to be in different name spaces.

Data folders are in their own name space. Therefore the name of a data folder can be the same as the name of any other object, except for another data folder at the same level of the hierarchy.

Waves and variables (numeric and string) are in the same name space and so Igor will not let you create a wave and a variable in a single data folder with the same name.

An annotation is local to the window containing it. Its name must be unique only among annotations in the same window. The same applies for controls and rulers. Data folders, waves, variables, windows, symbolic paths and pictures are global objects, not associated with a particular window.

The names of global objects, except for data folders, are required to be distinct from the names of macros, functions (built-in, external or user-defined) and operations (built-in or external).

Here is a summary of the four global name spaces:

Name Space	Requirements
Data folders	Names must be distinct from other data folders at the same level of the hierarchy.
Waves, variables, windows	Names must be distinct from other waves, variables (numeric and string), windows.
Pictures	Names must be distinct from other pictures.
Symbolic paths	Names must be distinct from other symbolic paths.

Renaming Objects

You can use Misc→Rename Objects or Data→Rename to rename waves, variables, strings, symbolic paths, and pictures. Both of these invoke the Rename Objects dialog.

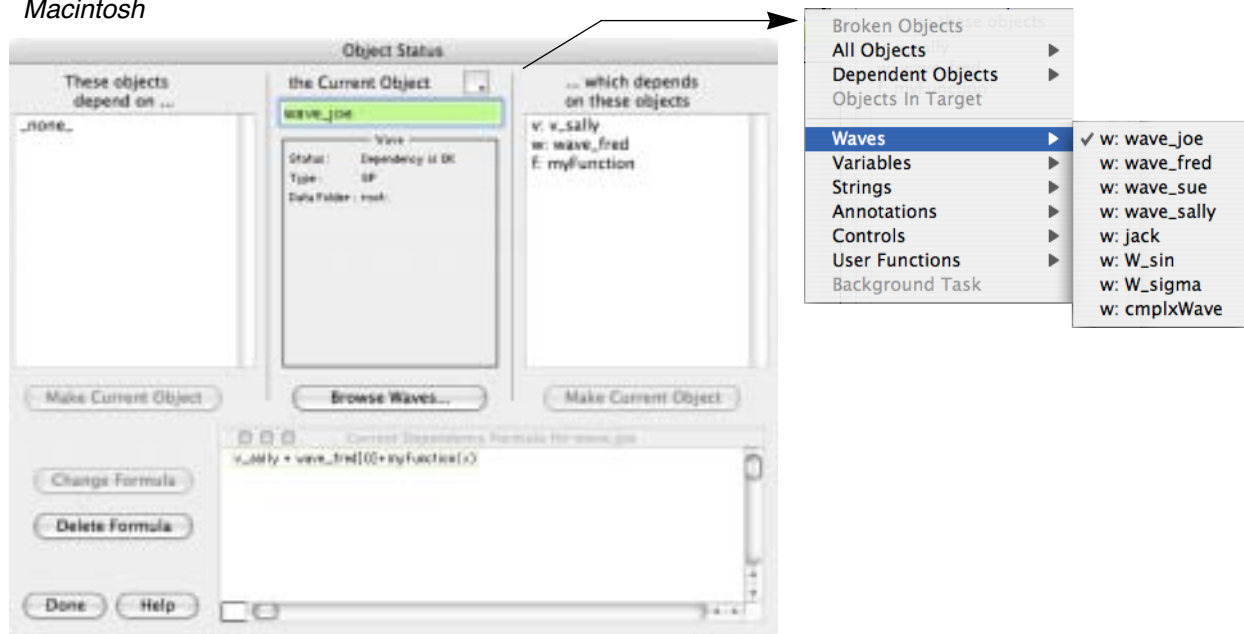

Graphs, tables, page layouts, notebooks, control panels and XOP target windows (e.g., Gizmo 3D plots) are renamed using the **DoWindow** operation (see page V-110) which you can build using the Window Control dialog. See **The Window Control Dialog** on page II-53.

You can use the DataBrowser to rename data folders, waves, and variables. See **Data Browser** on page II-114.

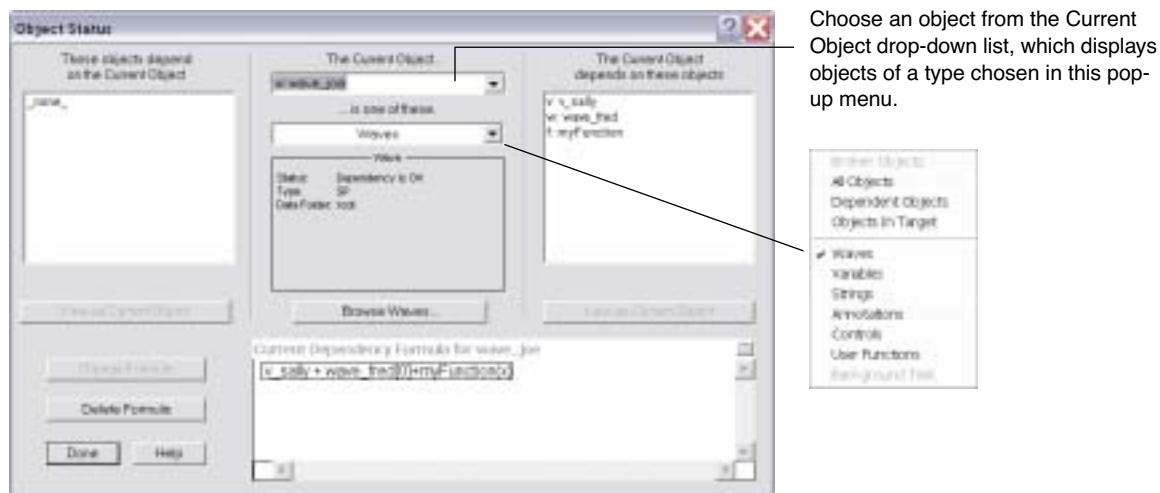

The Object Status Dialog

You can examine the status and interdependencies of named Igor objects with the Object Status dialog. See Chapter IV-9, **Dependencies**, for a discussion of object dependencies. You won't need to use this dialog unless you've got a fairly complex Igor experiment with lots of objects.

Macintosh

Windows

The dialog displays the properties of one object, called the “Current Object”. The name of the current object appears at the top center of the dialog. You can choose a new current object from the Current Object pop-up menu.

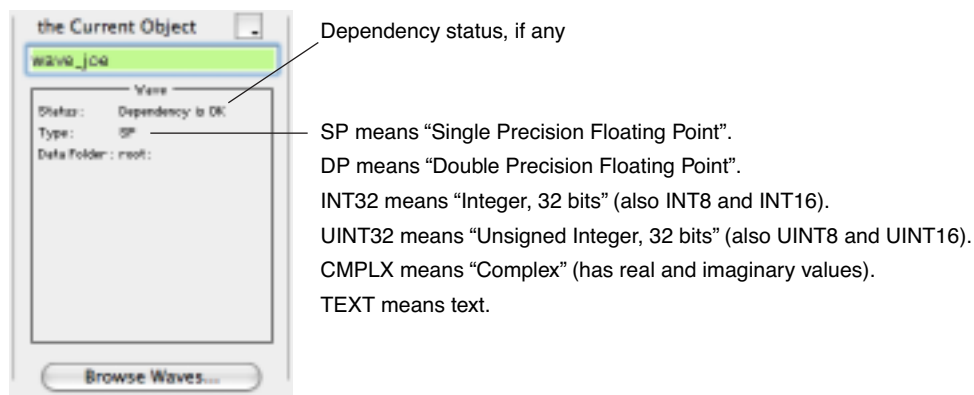

You can also choose a new current object by selecting an object from either of the two **dependency lists** on the left and right of the current object and clicking View as Current Object, or by double-clicking in either list.

Items in the lists and submenus are object names preceded by a key indicating the type of object:

Key	Object Type
a:	annotation
c:	control
f:	function
s:	string

Key	Object Type
t:	task (background task)
v:	variable
w:	wave
=:	dependency formula

The current value, dependency status, and other information about the current object is displayed in the box below the name of the current object. Depending on the type of object, a button may also be present for editing or examining that object.

Other current object information is displayed in a windoid near the bottom of the dialog. If the object is a “dependent” object, the dependency formula is shown. This formula can be changed or deleted by clicking the appropriate buttons:

Dependencies and dependency formulas are explained further in Chapter IV-9, **Dependencies**.

You can edit the current value of most nondependent objects in the windoid:

For some nondependent objects, you can also establish a new dependency formula. Click the New Formula button, and an empty formula is created. Enter the desired formula and click Change Formula:

This example established the dependency formula:

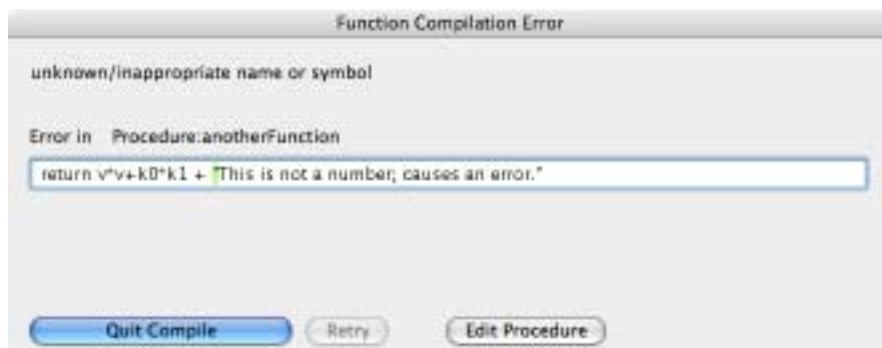

```
myGlobalVar := K0+K1*sin(K2)
```

Whenever K0, K1, or K2 changes, myGlobalVar will be updated using this formula.

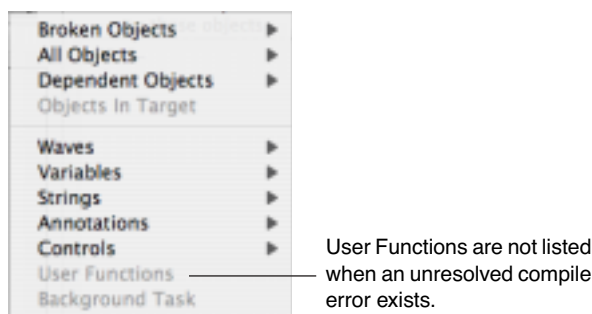

User Functions

You can edit the “current value” of a user-defined function, too. However, if you introduce an error and click Change Function, the function compiler will display an error dialog.

If you then click Quit Compile, the Object Status dialog will come back up, but it will appear as if all the user-defined functions have vanished.

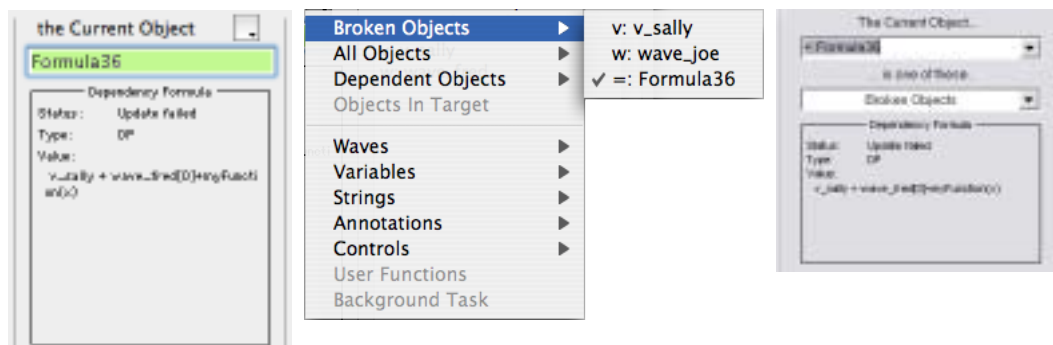

The functions have *not* vanished; Igor just can't display information about functions unless all the procedure windows compile successfully. When you fix the error, the user-defined functions will return.

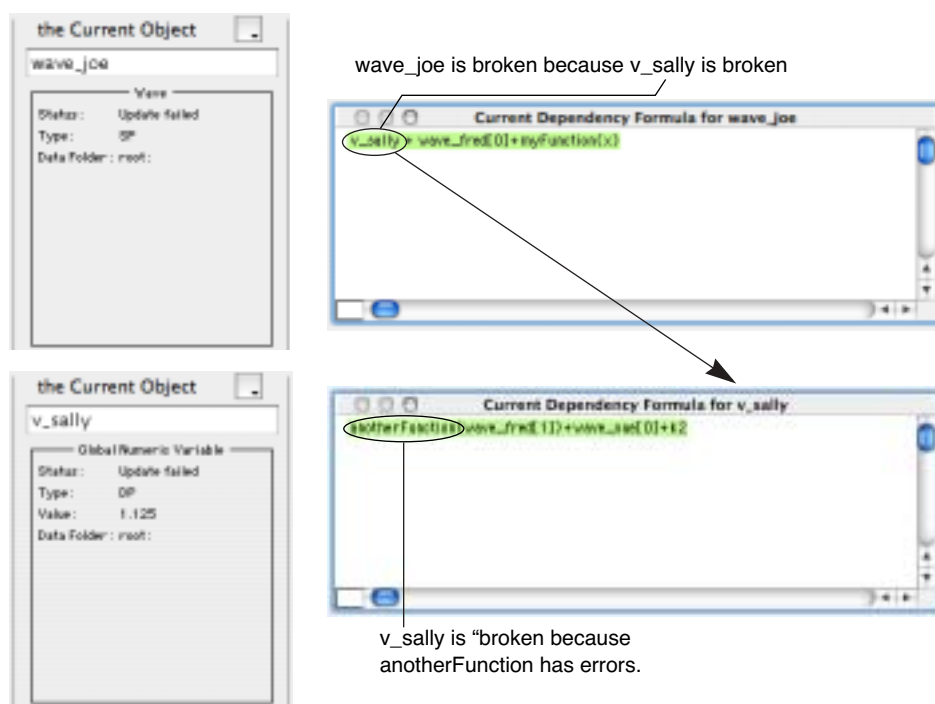

For this reason, it really makes more sense for you to click the Edit Procedure button in the error dialog. This brings up the procedure window in which the function is defined, but it does exit the Object Status dialog first (which would be devoid of function information, anyway). You should fix the error, and then reselect the Object Status dialog. You will find that the function is still the current object, and that all is well.

Broken Objects

If you *don't* fix errors in the user-defined function text, objects that reference the erroneous function will be "**broken**". Those objects are listed in the Broken Objects submenu. The Status field will show why the object is broken.

The usual causes for "Update failed" are either a syntax error in the dependency formula, or some object that the current object depends on (either directly or indirectly) has an error, has been renamed, or no longer exists. In this example, it is the unresolved error in the function `anotherFunction` (see **User Functions** on page III-403) which prevents `v_sally` from updating, which in turn causes the update of `wave_joe` through `Formula36` to fail:

Pictures

Igor can import pictures from other programs for display in graphs, page layouts and notebooks. It can also export pictures from graphs, page layouts and tables for use in other programs. Exporting is discussed in Chapter III-5, **Exporting Graphics (Macintosh)**, and Chapter III-6, **Exporting Graphics (Windows)**. This section discusses how you can import pictures into Igor, what you can do with them and how Igor stores them.

For information on importing images as data rather than as graphics, see **Loading Other Files** on page II-150.

Importing Pictures

There are three ways to import a picture.

- Pasting from the Clipboard into a graph, layout, or notebook
- Using the Pictures dialog to import a picture from a file or from the Clipboard
- Using the **LoadPICT** operation (see page V-309) to import a picture from a file or from the Clipboard

Each of these methods, except for pasting into a notebook, creates a *named*, global picture object that you can use in one or more graphs or layouts. Pasting into a notebook creates a picture that is local to the notebook.

This table shows the types of graphics formats from which Igor can import pictures:

Format	How To Import	Notes
PICT	Paste or use Misc→Pictures or LoadPICT	Macintosh only
EMF (Enhanced Metafile)	Paste or use Misc→Pictures or LoadPICT	Windows only
BMP (Windows bitmap)	Use Misc→Pictures or LoadPICT	Windows only BMP is sometimes called DIB (Device Independent Bitmap).
PNG (Portable Network Graphics)	Use Misc→Pictures or LoadPICT	Cross-platform bitmap format
JPEG	Use Misc→Pictures or LoadPICT	Cross-platform bitmap format

Format	How To Import	Notes
TIFF (Tagged Image File Format)	Use Misc→Pictures or LoadPICT	Cross-platform bitmap format
EPS (Encapsulated PostScript)	Use Misc→Pictures or LoadPICT	High resolution vector format. Requires PostScript printer. A screen preview is displayed on screen.

EPS files usually include a screen preview. The screen preview format is PICT on Macintosh and TIFF on Windows.

The platform-dependent formats (PICT, EMF, BMP) are drawn as gray boxes when displayed on the non-native format. The cross-platform formats can be displayed on either platform, except that Macintosh EPS pictures display as boxes on Windows, because the screen preview format (PICT) is platform-dependent. Also, EPS pictures which have no screen preview display as boxes.

EPS pictures provide the highest quality but should only be used if you are certain you will be printing on a PostScript printer or exporting to a PostScript-savvy application such as Adobe Illustrator.

When non-EPS pictures are used in a graphic that is exported as EPS, the picture is rendered as a bitmap which has lower quality than an EPS picture.

Problem With EPS Pictures On Mac OS X

On Mac OS X, printing an embedded EPS picture is problematic and required that WaveMetrics implement a workaround. The workaround is to enable “LaserWriter 8 compatibility mode”. This mode makes the Mac OS X PostScript printer driver behave like the Mac OS 9 LaserWriter 8 driver, which supported embedded EPS pictures.

For some unknown reason, the workaround interferes with the printing of Asian fonts, which print as Courier. Because of this problem, it is not possible to print both Asian fonts and embedded EPS graphics.

The compatibility mode which makes EPS printing work is off by default if the system language is Asian and on by default otherwise.

You can manually turn the workaround off by executing

```
SetIgorOption WantLW8Compatibility = 0    // No EPS printing, Asian fonts OK.
```

and turn it on by executing

```
SetIgorOption WantLW8Compatibility = 1    // No Asian fonts, EPS OK printing.
```

The Picture Collection Stores Named Pictures

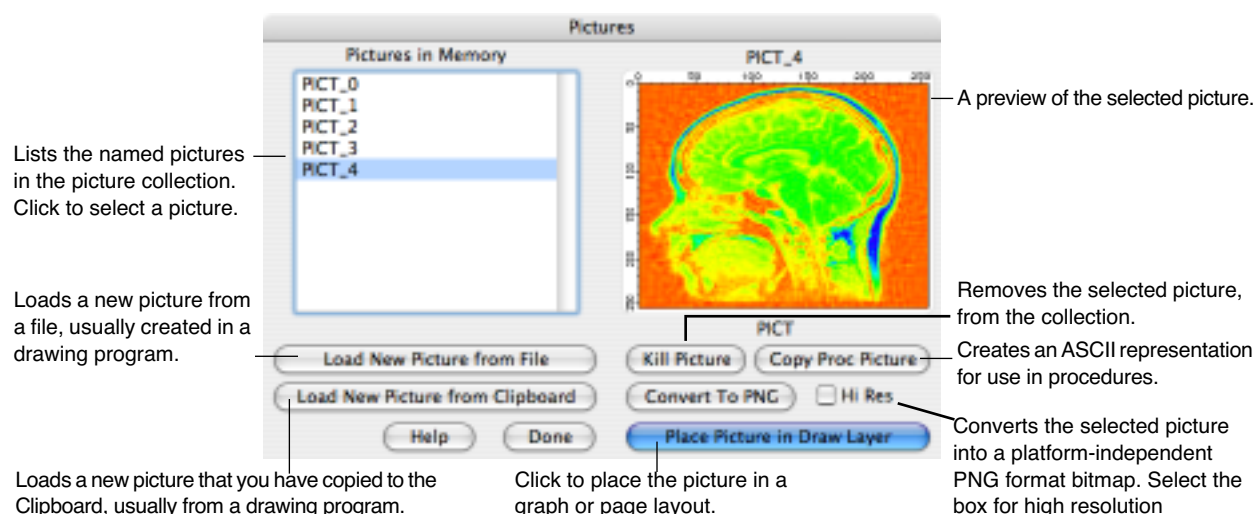

When you create a named picture using one of the techniques listed above, Igor stores it in the current experiment’s **picture collection**. When you save the experiment, the picture collection is stored in the experiment file. You can inspect the collection using the Pictures dialog via the Misc menu.

Igor gives names to pictures so they can be referenced from an Igor procedure. For example, if you paste a picture into a layout, Igor assigns it a name of the form “PICT_0” and stores it in the picture collection. If you then close the layout and ask Igor to create a recreation macro, the macro will reference the picture by name.

You can rename a named picture using the Rename Objects dialog in the Misc menu, or the **RenamePICT** operation (see page V-459). You can kill a named picture using the Pictures dialog or the **KillPICTs** operation (see page V-286).

Pictures Dialog

The Pictures dialog permits you to view the picture collection, to add pictures, to remove pictures and to place a picture into a graph or page layout. It also can place a copy of a picture into a formatted notebook. To invoke it, choose Pictures from the Misc menu.

The Kill This Picture button will be dimmed if the selected picture is used in a currently open graph or layout.

Note: Igor determines if a picture is in use by checking to see if it is used in an *open* graph or layout window.

If you kill a graph or layout that contains a picture and create a recreation macro, the recreation macro will *refer* to the picture by name. However, Igor does not check for this. It will consider the picture to be unused and will allow you to kill it. If you later run the recreation macro, an error will occur when the macro attempts to append the picture to the graph or layout. Therefore, don't kill a picture unless you are sure that it is not needed.

Notebook Pictures

When you paste a picture into a formatted notebook, you create a notebook picture. These work just like pictures in a word processor document. You can copy and paste them. These pictures will not appear in the Pictures or Rename Objects dialogs.

Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. An Igor extension is called an "XOP" (short for "external operation"). The term XOP comes from that fact that, originally, adding a command line operation was all that an extension could do. Now extensions can add operations, functions, menus, dialogs and windows.

WaveMetrics XOPs

The Igor Extensions and More Extensions folders contain XOPs that we developed at WaveMetrics. These add capabilities such as file-loading and instrument control to Igor and also serve as examples of what XOPs can do. These XOPs range from very simple to rather elaborate. Most XOPs come with help files that describe their operation.

The WaveMetrics XOPs are described in the XOP Index help file, accessible through the Windows→Help Windows submenu.

Third Party Extensions

A number of Igor users have written XOPs to customize Igor for their particular fields. Some of these are freeware, some are shareware and some are commercial programs. WaveMetrics publicizes third party XOPs through our Web page. Also, we make some third party XOPs available via FTP. See **FTP Sites** on page II-14 for details on FTP.

Activating Extensions

The Igor installer creates a folder called Igor Extensions at the same level on your hard disk as the Igor application. The Igor installer puts some XOP files in this folder. XOPs in this folder are loaded when Igor starts up.

The installer puts less-frequently used XOPs in the More Extensions folder. These are not available unless you activate them.

If you place in the Igor Extensions folder an alias (*Macintosh*) or shortcut (*Windows*) for an XOP file or a folder containing XOP files, Igor loads those files also. This is the recommended way to activate an XOP that does not reside in the Igor Extensions folder.

If you drag files, aliases or shortcuts into or out of the Igor Extensions folder, you must restart Igor before the change takes effect.

See **Creating Igor Extensions** on page IV-151 if you are a programmer interested in writing your own XOPs.

XOPs on Intel Macintosh

To run an XOP on Intel Macintosh it must be ported to the Intel architecture. WaveMetrics has ported most of its XOPs and distributes them as universal executables, which means that they run on both PowerPC and Intel Macintosh. The Igor Pro 6 application is also universal.

Because third-party libraries are not yet available, the following WaveMetrics XOPs have not yet been ported to run with the Intel version of Igor Pro: HDF Loader, MLLoadWave, NIGPIB, NIGPIB2, and XLLoadWave.

In addition, the NetCDF Loader XOP, written by Igor user Katsuhisa Kitano and ported to Mac OS X by WaveMetrics, has not yet been ported to Intel.

If you use a third-party XOP that has not yet been ported to Intel, you can not run it with the Intel version of Igor.

The Igor Pro installer places non-Intel WaveMetrics Macintosh XOPs in the PPC Extensions folder.

If you run the Intel Macintosh version of Igor Pro with a PowerPC-only XOP installed, it will not display an error message and will ignore the PowerPC-only XOP. Similarly, if you run the PowerPC version of Igor with an Intel-only XOP installed, it will not display an error message and will ignore the Intel-only XOP.

Running PowerPC XOPs on Intel Macintosh

If you need to run an XOP that has not been ported to Intel Macintosh, you must run the PowerPC version of Igor Pro. You can do this on an Intel Macintosh by checking the Open Using Rosetta checkbox in the Finder Info window for the Igor Pro application located in the Igor Pro folder.

With the Open Using Rosetta checkbox checked, the PowerPC code in the Igor Pro 6 application package will run any PowerPC XOPs that you invoke.

Memory Management

On Mac OS X, each 32-bit application (such as Igor Pro) is allocated 4 GB of virtual address space. On Windows, 32-bit applications are allocated 2 GB of virtual address space by default but there is a technique (explained below) for increasing this to 3 GB or 4 GB.

Theoretically, applications can allocate memory up the limit of the virtual address space. The operating system allocates physical memory as necessary. If the total amount of allocated virtual memory exceeds the total amount of physical memory, the operating system will temporarily write some data to disk and load other data into physical memory — a process called “swapping”. This can make the computer very slow.

When a program is launched, the operating system maps the program’s code into its virtual address space, thereby diminishing the space available for data. During the program’s initialization, it allocates many

blocks of data, thousands in Igor's case, for things like windows, controls and internally-used structures. This further reduces the amount of virtual memory space available for data.

As you work, creating windows, procedures, variables, waves and other objects, Igor allocates more blocks of virtual memory. When you kill a window, wave or other object, Igor deallocates blocks of virtual memory. This leaves free blocks in the virtual memory space.

Blocks of virtual memory space that are free because of deallocation are generally discontinuous. The largest contiguous block is smaller than the total amount of free virtual memory. The free virtual memory space is split into fragments that can not be joined because they are separated by allocated blocks. As you allocate and deallocate memory, the virtual memory space becomes more and more fragmented.

When you create an object, for example, a wave, Igor needs a contiguous block of virtual memory. If the space needed for the wave is larger than the largest contiguous block of virtual memory, the allocation will fail and Igor will return an out-of-memory error.

Increasing Virtual Memory Space in Windows XP

By default, 32-bit applications like Igor get a 2 GB virtual address space. It is possible to increase this to 3 GB in Windows XP Professional (32-bit version) and to 4 GB in Windows XP Professional x64 (64-bit version). This feature is described at:

<http://www.microsoft.com/whdc/system/platform/server/PAE/PAEmem.mspx>

This Windows XP Professional feature requires that a special flag be set in the Igor.exe file. This special flag is set in Igor Pro 5.05 and later. The rest of this discussion assumes you are running Igor Pro 5.05 or later.

If you are running Windows XP Professional x64 (64-bit), the operating system will allow Igor to use 4 GB of virtual address space.

If you are running Windows XP Professional (32-bit) you need to change a setting on your computer to enable the 3 GB virtual address space. You need to add the /3GB flag to your C:\boot.ini file.

Note: Be careful! If you mess up your boot.ini file, your computer will not boot. This procedure should be attempted only by advanced Windows computer users.

The boot.ini is invisible by default. To see it you must use Explorer's Tools→Folder Options to enable viewing hidden files and disable hiding protected system files. Alternatively you can use the System control panel, Advanced Tab, Startup and Recovery section to edit it.

Back up the boot.ini file before making any changes to it.

Open boot.ini in Notepad and add the /3GB flag to the appropriate partition. For example, after adding the flag, the relevant line in boot.ini may look like this:

```
multi(0)disk(0)rdisk(0)partition(1)\WINDOWS="Microsoft Windows XP Professional"
/fastdetect /3GB
```

When you next boot, the operating system will allow Igor to use 3 GB of virtual address space instead of 2 GB.

The /3GB flag has no effect on programs that do not have the special flag set.

Macintosh System Requirements

Igor Pro 6 requires Mac OS X 10.3.9 or later. It runs native on PowerPC and Intel processors.

Igor Pro 6 does not run on Mac OS 9.

Windows System Requirements

Igor Pro requires Windows 2000, Windows XP, Windows Vista or later.

Igor Pro 6 does not run on Windows 95, Windows 98, Windows ME, or Windows NT.

Crashes

A crash results from a software bug and prevents a program from continuing to run. Crashes are highly annoying at best and, at worst, can cause you to lose valuable work.

WaveMetrics uses careful programming practices and extensive testing to make Igor as reliable and bug-free as we can. However in Igor as in any complex piece of software it is impossible to exterminate all bugs. Also, crashes can occur in Igor because of bugs in other software, such as printer drivers, video drivers or system extensions.

We are committed to keeping Igor a solid and reliable program. If you experience a crash in Igor, we want to know about it. Please send a report to support@wavemetrics.com.

When reporting a crash to WaveMetrics, please include the following information:

- The exact version of Igor Pro (e.g., 6.01) that you are running.
- The exact operating system (e.g., Mac OS X 10.4.7, Windows XP) that you are running.
- A description of what actions preceded the crash.

If the crash is reproducible, please send an Igor experiment so that we can also try to reproduce it at WaveMetrics.

Irreproducible crashes are very hard to debug. The most helpful thing you can do is to send a crash log file. Mac OS X and Windows produce crash log files. These files sometimes provide useful clues.

On Mac OS X the crash log file will be named “Igor Pro.crash.log” and is typically in “/<user>/Library/Logs/CrashReporter/”. Send a copy to support@wavemetrics.com.

On Windows, the crash log file is named “drwtsn32.log” and is typically in “C:\Documents and Settings\All Users\Application Data\Microsoft\Dr Watson\”. Send a copy to support@wavemetrics.com. This file is hidden by default so you must make hidden files visible using Tools→Folder Options→View in the Windows desktop.

Preferences

Igor Preferences Directory 410

How to Use Preferences 410

Captured Preferences 411

 Current Captured Preference Values..... 411

 Capturing Other Settings..... 412

When Preferences Are Applied 412

Overview

Preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, and procedure windows, and the *appending* of traces to graphs and columns to tables. In addition, preferences affect the command window, default font, and font size menus in new experiments.

You can turn preferences off or on using the Misc menu. Normally you will run with preferences on.

Preferences are automatically off while a procedure is running so that the effects of the procedure will be the same for all users. See the **Preferences** operation (see page V-436) for further information.

When preferences are off, factory default values are used for settings such as graph size, position, line style, size and color. When preferences are on, Igor applies your preferred values for these settings.

Preferences differ from *settings* (the Miscellaneous Settings dialog) in that settings generally take effect immediately, while preferences are used when something is created. See **Miscellaneous Settings** on page III-395.

Igor Preferences Directory

Preferences are stored in a per-user directory. The location of this directory depends on your operating system and configuration, but here are some typical locations:

Mac OS X `hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro 6 PowerPC:`
 or
 `hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro 6 Intel:`

Windows `C:Documents and Settings:<user>:Application Data:WaveMetrics:Igor Pro 6:`

where `<user>` is the name of the current user. The preferences directory may be hidden by some operating systems.

You can find the operating-system-defined location for preferences by executing this command:

```
Print SpecialDirPath("Preferences", 0, 0, 0)
```

Deleting the preferences directory effectively reverts all preferences to factory defaults. You should use the Capture Prefs dialogs, described in **Captured Preferences** operation on page III-413, to revert preferences more selectively.

Other information is stored in this directory, such as the screen position of dialogs, a few dialog settings, colors recently selected in the color palette, window stacking and tiling information, page setups, font substitution settings, and dashed line settings.

How to Use Preferences

Preferences are always on when Igor starts up. You can turn preferences off by choosing Preferences Off in the Misc menu.

You can also turn preferences on and off with the **Preferences** operation (see page V-436).

Preferences are set by Capture Preferences dialogs, the Tile or Stack Windows dialog, and some dialogs such as the Dashed Lines dialog.

There is just one set of preferences for all experiments. This means that preferences set while running one experiment will be in effect when you run the next experiment. This is handy because you only need to specify your preferences once.

In general, *preferences are applied only when something new is created* such as a new graph, a new trace in a graph, a new notebook, a new column in a table, and then only if preferences are on.

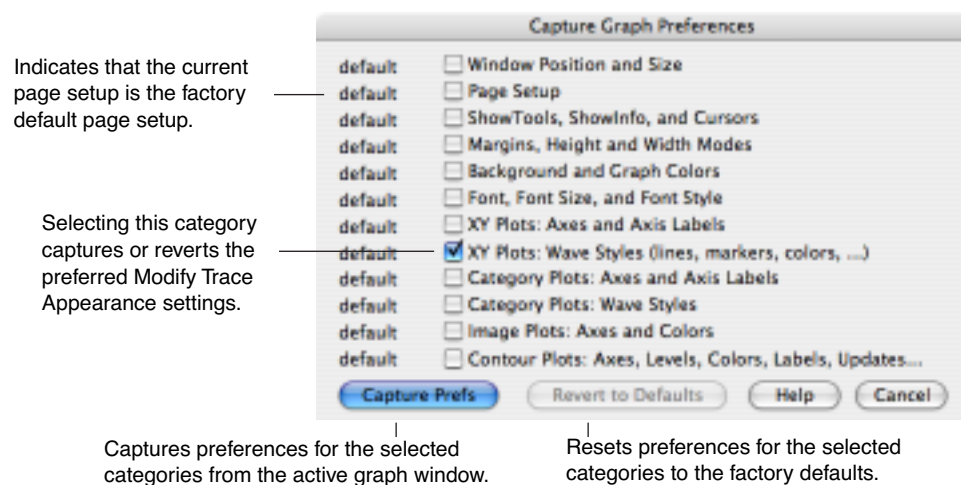

Preferences are normally in effect only for *manual* (“point-and-click”) operation, not for user-programmed operations in Igor procedures. See **When Preferences Are Applied** on page III-414.

Captured Preferences

You set most Preference values by capturing the current settings of the active window with the Capture Prefs item in the menu for that window. (The dialog to capture the Command Window preferences is found in the Command/History Settings submenu of the Misc menu.) The dialogs are described in more detail in the chapter that discusses each type of window. For instance, see **Graph Preferences** on page II-278.

As an example, suppose you want your graphs to always draw appended waves with a one-half point blue line, rather than the factory default one point red line. You can set your preference by creating a graph with one wave displayed using a one-half point blue line, and then “capturing” that preferred setting with the Capture Graph Preferences dialog.

Choose Capture Graph Prefs from the Graph menu:

Save the wave style preference by selecting the XY Plots: Wave Styles category and clicking Capture Prefs. From now on, when you append a wave to an existing graph, or create a new graph containing a trace, the trace will be displayed with your preferred one-half point blue line.

Most capture preferences dialogs are like this Capture Graph Preferences dialog; they have various categories with checkboxes. Selecting a category means that you wish to change the preferences for that category. You may either capture the current settings for that category by clicking the Capture Prefs button, or you may revert the preferences for that category by clicking the Revert to Defaults button. If a category has been reverted to its default setting, “default” is indicated to the left of the checkbox. If “default” is not present, this means that the category settings have previously been captured.

Current Captured Preference Values

The Capture Preferences dialogs do not show the current *values* for the settings in the categories. The only way to discover what captured values are is to create a new window of that type and examine the settings with dialogs or readback functions. Any value not set to the factory default value must have been set by the preferences. (To check the factory default values, create a new window with Preferences off.)

For example, to determine what the values captured by the Capture Graph Preferences dialog are:

- Turn Preferences on (in the Misc menu).
- Create a new graph.
- Append some waves.

- Create a graph recreation macro using the Window Control dialog, and examine the values assigned by the resulting macro (this works well because graph recreation macros generate commands only to change values from their factory defaults).
- Or, use the Modify Waves Appearance dialog to observe the settings for the displayed waves. These are the captured user-preferred values.

Capturing Other Settings

In addition to the preferences captured by the various Capture Prefs dialogs, Igor remembers a number of other settings. Many of these can be set using the Miscellaneous Settings dialog, described in **Miscellaneous Settings** on page III-395.

Some settings are captured in dialogs whose main purpose is to change the *current* value of some settings. Such a dialog is the Default Font dialog:

It can capture the preferred Default Font with or without changing the current value. The Dashed Lines and Tile or Stack Windows dialogs also work this way.

The positions of dialogs on your desktop are always remembered in the preferences file. On Macintosh only, Recent Colors are remembered if the appropriate checkbox in the Misc Settings dialog is selected.

On both Macintosh and Windows, the font sizes you add to the Text Size menu are automatically remembered, as well as fonts substitution settings and various other dialog settings.

When Preferences Are Applied

In general, *preferences are applied only when something new is created* such as a new graph, a new wave in a graph, a new notebook, a new column in a table, and then only if preferences are on. In some cases, preferences affect what happens when you create a new experiment.

Igor has, in effect, two independent settings for whether preferences are on or off. The Preferences On and Preferences Off items in the Misc menu control the setting for *manual* ("point-and-click") operations, and is initially (and normally) set to "on". Another setting is used when a procedure (macro or function) is executing, and is normally set to "off".

We usually don't want preferences to affect the behavior of procedures. If we allowed preferences to take effect during procedure execution, a change in preferences could change the effect of a procedure, making it unpredictable. For more information, see **Procedures and Preferences** on page IV-149.

Overview

Igor's user interface is unique in providing both a graphical user interface and a parallel path using command line operations. Although you can get by ignoring the command line, if you do so you will miss out on much of Igor's power and flexibility.

Even if you are a casual user you should learn at least the basics of assignment statements. Most users should read this entire chapter — especially those who expect to program Igor.

You can execute commands by typing them into the command line and pressing Return or Enter. You can also incorporate commands into procedures (functions and macros) that you write in the Procedure window. You can execute a procedure by typing its name in the command line or by choosing its item from the Macros menu. You can also use a notebook for entering commands. See **Notebooks as Worksheets** on page III-4.

You can type commands from scratch but often you will let Igor dialogs formulate and execute commands. You can view a record of what you have done in the history area of the command window and you can easily reenter, edit and reexecute commands stored there. See **Command Window Shortcuts** on page II-22 for details.

Multiple Commands

You can place multiple commands on one line if you separate them with semicolons. For example:

```
wave1= x; wave1= wave2/(wave1+1); Display wave1
```

You don't need a semicolon after the last command but it doesn't hurt.

Comments

Comments start with `//`, which end the executable part of a command line. The comment continues to the end of the line. There is no way to insert a comment in the middle of a command line.

Maximum Length of a Command

The total length of the command line must not exceed 400 characters.

There is no line continuation character in Igor. However, it is nearly always possible to break a single command up into multiple lines.

Parameters

Every place in a command where Igor expects a numeric parameter you can use a numeric expression. Similarly for a string parameter you can use a string expression. In an operation flag (e.g., `/N=<number>`), you must parenthesize expressions. See **Expressions as Parameters** on page IV-11 for details.

Liberal Object Names

In general, object names in Igor are limited to a restricted set of characters. Only letters, digits and the underscore character are allowed. Such names are called "standard names". This restriction is necessary to identify where the name ends when you use it in a command.

For waves and data folders only, you can also use "liberal" names. Liberal names can include almost any character, including spaces and dots (see **Liberal Object Names** on page III-400 for details). However, to define where a liberal name ends, you must quote them using single quotes.

In the following example, the wave names are liberal because they include spaces and therefore they must be quoted:

```
'wave 1' = 'wave 2'           // Right
wave 1 = wave 2               // Wrong - liberal names must be quoted
```

Note: Providing for liberal names requires extra effort and testing by Igor programmers (see **Programming with Liberal Names** on page IV-121) so you may occasionally experience problems using liberal names with user-defined procedures.

Data Folders

Data folders provide a way to keep separate sets of data from interfering with each other. You can examine and create data folders using the Data Browser (Data menu). There is always a root data folder and this is the only data folder that many users will ever need. Advanced users may want to create additional data folders to organize their data.

You can refer to waves and variables either in the current data folder, in a specific data folder or in a data folder whose location is relative to the current data folder:

```
// wave1 is in the current data folder
wave1 = <expression>

// wave1 is in a specific data folder
root:'Background Curves':wave1 = <expression>

// wave1 is in a data folder inside the current data folder
:'Background Curves':wave1 = <expression>
```

In the first example, we use an object name by itself (wave1) and Igor looks for the object in the current data folder.

In the second example, we use a full data folder path (root:'Background Curves:') plus an object name. Igor looks for the object in the specified data folder.

In the third example, we use a relative data folder path (: 'Background Curves:') plus an object name. Igor looks in the current data folder for a subdata folder named Background Curves and looks for the object within that data folder.

Important: The right-hand side of an assignment statement (described under **Assignment Statements** on page IV-4) is evaluated in the context of the data folder containing the destination object. For example:

```
root:'Background Curves':wave1 = wave2 + var1
```

For this to work, wave2 and var1 must be in the Background Curves data folder.

Examples in the rest of this chapter use object names alone and thus reference data in the current data folder. For more on data folders, see Chapter II-8, **Data Folders**.

Types of Commands

There are three fundamentally different types of commands that you can execute from the command line:

- assignment statements
- operation commands
- user-defined procedure commands

Here are examples of each:

```
wave1= sin(2*pi*freq*x)           // assignment statement
Display wave1,wave2 vs xwave      // operation command
MyFunction(1.2,"hello")           // user-defined procedure command
```

As Igor executes commands you have entered, it must determine which of the three basic types of commands you have typed. If a command starts with a wave or variable name then Igor assumes it is an assignment statement. If a command starts with the name of a built-in or external operation then the command is treated as an operation. If a command begins with the name of a user-defined macro, user-defined function or external function then the command is treated accordingly. Each of these types is discussed in greater detail under **Assignment Statements** on page IV-4, **Operation Commands** on page IV-9, and **User-Defined Procedure Commands** on page IV-9.

Chapter IV-1 — Working with Commands

Note that built-in functions can only appear in the right-hand side of an assignment statement, or as a parameter to an operation or function. Thus, the command:

```
sin(x)
```

is not allowed and you will see the error, “Expected wave name, variable name, or operation.” On the other hand, these commands are allowed:

```
print sin(1.567)           // sin is parameter of print command
wave1 = 5*sin(x)           // sin in right side of assignment
```

If, perhaps due to a misspelling, Igor can not determine what you want to do, it will put up an error dialog and the error will be highlighted in the command line.

Assignment Statements

Assignment statement commands start with a wave or variable name. The command assigns a value to all or part of the named object. An assignment statement consists of three parts: a destination, an assignment operator, and an expression. For example:

<u>wave1</u>	=	<u>1 + 2 * 3^2</u>
Destination		Expression
Assignment operator		

This assigns 19 to every point in wave1.

The spaces in the above example are not required. You could write:

```
wave1=1+2*3^2
```

See **Waveform Arithmetic and Assignments** on page II-80 for details on wave assignment statements.

In the following examples, str1 is a string variable, created by the String operation, var1 is a numeric variable, created by the Variable operation, and wave1 is a wave, created by the Make operation.

```
str1 = "Today is " + date()           // string assignment
str1 += ", and the time is " + time()  // string concatenation
var1 = strlen(str1)                   // variable assignment
var1 = pnt2x(wave1,numpts(wave1)/2)    // variable assignment
wave1 = 1.2*exp(-0.2*(x-var1)^2)       // wave assignment
wave1[3] = 5                           // wave assignment
wave1[0,;3]= wave2[p/3] *exp(-0.2*x)  // wave assignment
```

These all operate on objects in the current data folder. To operate on an object in another data folder, you need to use a data folder path:

```
root:'run 1':wave1[3] = 5             // wave assignment
```

See Chapter II-8, **Data Folders**, for further details.

If you use liberal wave names (see **Object Names** on page III-399), you must use quotes:

```
'wave 1' = 'wave 2'                  // Right
wave 1 = wave 2                       // Wrong
```

Assignment Operators

The assignment operator determines the way in which the expression is combined with the destination. Igor supports the following assignment operators:

Operator	Assignment Action
=	Destination contents are set to the value of the expression.
+=	Expression is added to the destination.
-=	Expression is subtracted from the destination.
*=	Destination is multiplied by the expression.
/=	Destination is divided by the expression.
:=	Destination is dynamically updated to the value of the expression whenever the value of any part of the expression changes. The := operator is said to establish a “dependency” of the destination on the expression.

For example:

```
wave1 = 10
```

sets each Y value of the wave1 equal to 10, whereas:

```
wave1 += 10
```

adds 10 to each Y value of wave1. This is equivalent to:

```
wave1 = wave1 + 10
```

The assignment operators =, := and += work with string assignment statements but -=, *= and /= do not. For example:

```
String str1; str1 = "Today is "; str1 += date(); Print str1
```

prints something like “Today is Fri, Mar 31, 2000”.

For more information on the := operator, see Chapter IV-9, **Dependencies**.

Operators

Here is a complete list of the operators that Igor supports in the expression part of an assignment statement in order of precedence:

Operator	Effect
^	Exponentiation
– ! ~	Negation, logical complement, bitwise complement
* /	Multiplication, division
+ –	Addition or string concatenation, subtraction
== != > < >= <=	Comparison operators
& %^	Bitwise AND, bitwise OR, bitwise XOR
&& ? :	Logical AND, logical OR, conditional operator
\$	Substitute following string expression as name

Unary negation changes the sign of its operand. Logical complementation changes nonzero operands to zero and zero operands to 1. Bitwise complementation converts its operand to an unsigned integer by truncation and then changes it to its binary complement.

Exponentiation raises its left-hand operand to a power specified by its right-hand operand. That is, 3^2 is written as 3^2 . In an expression a^b , if the result is assigned to a real variable or wave, then a must not be

Chapter IV-1 — Working with Commands

negative if *b* is not an integer. If the result is used in a complex expression, any combination of negative *a*, fractional *b* or complex *a* or *b* is allowed.

If the exponent is an integer Igor evaluates the expression using only multiplication. There is no need to write a^2 as $a*a$ to get efficient evaluation — Igor does the equivalent automatically. If, on the other hand, the exponent is not an integer then the evaluation is performed using logarithms, hence the restriction on negative *a* in a real expression.

Logical OR (`|`) and logical AND (`&&`) determine the truth or falseness of pairs of expressions. The AND operation returns true only when both expressions are true; OR will return true if *either* is true. As in C, true is *any* nonzero value, and false is zero. The operations are undefined for NaNs. These operators are not available in complex expressions.

The logical operators are evaluated from left to right, and an operand will not be evaluated if it is not necessary. For the example:

```
if(MyFunc1() && MyFunc2())
```

when `MyFunc1()` returns false (zero), then `MyFunc2()` will not be evaluated because the entire expression is already false. This can produce unexpected consequences when the right-hand expression has side effects, such as creating waves or setting global values.

Bitwise AND (`&`), OR (`|`), and XOR (`%^`) convert their operands to an unsigned integer by truncation and then return their binary AND, OR or exclusive OR.

The conditional operator (`? :`) is a shorthand form of an if-else-endif expression. In the statement:

```
<expression> ? <TRUE> : <FALSE>
```

the first operand, `<expression>`, is the test condition; if it is nonzero then Igor evaluates the `<TRUE>` operand; otherwise `<FALSE>` is evaluated. Only one operand is evaluated according to the test condition. This is the same as if you had written:

```
if( <expression> )
    <TRUE>
else
    <FALSE>
endif
```

The “.” character in the conditional operator must always be separated from the two adjacent operands with a space. If you omit either space, you will get an error (“No such data folder”) because the expression can also be interpreted as part of a data folder path. To be safe, always separate the operands from the operator symbols with a space.

The operands must be numeric; for strings, use the **SelectString** function. When using complex expressions with the conditional operator, only the real portion is used when the operator evaluates the expression.

The conditional operator can easily cause confusion, so you should exercise caution when using it. For example, it is unclear from simple inspection what Igor may return for

```
1 ? 2 : 3 ? 4 : 5
```

(4 in this case), whereas

```
1 ? 2 : (3 ? 4 : 5)
```

will return 2. Always use parentheses to remove any ambiguity.

The comparison operators return 1 if the result of the comparison is true or 0 if it is false. For example, the `==` operator returns 1 if its operands are equal or 0 if they are not equal. The `!=` operator returns the opposite. Because comparison operators return the values 1 or 0 they can be used in interesting ways. The assignment:

```
wave1 = sin(x)*(x<=50) + cos(x)*(x>50)
```

sets `wave1` so that it is a sine wave below $x=50$ and a cosine wave above $x=50$. See also **Example: Comparison Operators and Wave Synthesis** on page II-84.

Note that the double equal sign, `==`, is used to mean equality while the single equal sign, `=`, is used to indicate assignment.

Because of roundoff error, using `==` to test two numbers for equality may give incorrect results. It is safer to use `<=` and `>=` to see if a number falls in a narrow range. For example, imagine that you want to compare a variable to see if it is equal to one-third. The expression:

```
(v1 == 1/3)
```

is subject to failure because of roundoff. It is safer to use something like

```
((v1 > .33332) && (v1 < .33334))
```

If the numbers are integers then the use of `==` is safe because integers smaller than 2^{53} (approximately 10^{16}) are represented precisely in double-precision floating point numbers.

The previous discussion on operators has assumed numeric operands. The `+` operator is the only one that works with both numeric *and* string operands. For example, if `str1` is a string variable then the assignment statement

```
str1 = "Today is " + "a nice day"
```

assigns the value "Today is a nice day" to `str1`. The other string operator, `$` is discussed in **String Substitution Using \$** on page IV-14.

Unless specified otherwise by parentheses, unary negation or complementation are carried out first followed by exponentiation then by multiplication or division followed by addition or subtraction then by comparison operators. The wave assignment:

```
wave1 = ((1 + 2) * 3) ^ 2
```

assigns the value 81 to every point in `wave1`, but

```
wave1 = 1 + 2 * 3 ^ 2
```

assigns the value 19.

Note: `-a^b` is an exception to this rule and is evaluated as `-(a^b)`.

The precedence of string substitution, substrings, and wave indexing is somewhat complex. When in doubt, use parenthesis to enforce the precedence you want.

Obsolete Operators

As of Igor Pro 4.0, the old bitwise complement (`%~`), bitwise AND (`%&`), and bitwise OR (`%|`) operators have been replaced by new versions that omit the `%` character from the operator. These old bitwise operators can still be used interchangeably with the new versions.

Operands

In addition to literal numbers like 3.141 or 27, operators can operate on variables and function values. In the assignment statement:

```
var1 = log(3.7) + var2
```

the operator `+` operates on the function value returned by `log` and on the variable `var2`. Functions and function values are discussed later in this chapter.

Numeric Type

In Igor, each numeric destination object (wave or variable) has its own numeric type. The numeric type consists of the numeric precision (e.g., double precision floating point) and the number type (real or complex). Waves can be single or double precision floating point or various sizes of integer but variables are always double precision floating point.

The numeric precision of the destination does not affect the calculations. With the exception of a few operations that are done in place such as the FFT, all calculations are done in double precision.

Chapter IV-1 — Working with Commands

Although waves can have integer numeric types, wave expressions are always evaluated in double precision floating point. The floating point values are converted to integers by rounding as the final step before storing the value in the wave. If the value to be stored exceeds the range of values that the given integer type can represent, the results are undefined.

The number type of the destination determines the initial number type (real or complex) of the assignment expression. This is important because Igor can not deal with “surprise” or “runtime” changes in number type. An example would be taking the square root of a negative number requiring that all following arithmetic be done using complex numbers.

Here are some examples:

```
Variable a, b, c, var1
Variable/C cvar1
Make wave1

var1= a*b
cvar1= c*cmplx(a+1,b-1)
wave1= var1 + real(cvar1)
```

The first expression is evaluated using the real number type. The second expression contains a mixture of two types. The multiplication of c with the result of the cmplx function is evaluated as complex while the arguments to the cmplx function are evaluated as real. The third example is evaluated as real except for the argument to the real function which is evaluated as complex.

Constant Type

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]
```

```
StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

You can use the static prefix to limit the scope to the given source file. For debugging, you can use the Override keyword as with functions.

These declarations can be used in the following ways:

```
constant kFoo=1,kBar=2
strconstant ksFoo="hello",ksBar="there"

static constant kFoo=1,kBar=2
static strconstant ksFoo="hello",ksBar="there"

override constant kFoo=1,kBar=2
override strconstant ksFoo="hello",ksBar="there"
```

Programmers may find that using the “k” and “ks” prefixes will make their code easier to read.

Names for numeric and string constants can conflict with all other names. Duplicate constants of a given type are not allowed (except static in different files and when used with Override). The only true conflict is with variable names and with certain built-in functions that do not take parameters such as pi. Variable names override constants, but constants override functions such as pi.

Dependency Assignment Statements

You can set up global variables and waves so that they automatically recalculate their contents when other global objects change. See Chapter IV-9, **Dependencies**, for details.

Operation Commands

An operation is a built-in or external routine that performs an action but, unlike a function, does not directly return a value. Here are some examples:

```
Make/N=512 wave1
Display wave1
Smooth 5, wave1
```

Operation commands perform the majority of the work in Igor and are automatically generated and executed as you work with Igor using dialogs.

You can use these dialogs to experiment with operations of interest to you. As you click in a dialog, Igor composes a command. This provides a handy way for you to check the syntax of the operation or to generate a command for use in a user-defined procedure. See Chapter V-1, **Igor Reference**, for a complete list of all built-in operations. Another way to learn their syntax is to use the Igor Help Browser's Command Help tab. See **Command Help Tab** on page II-6.

The syntax of operation commands is highly variable but in general consists of the operation name, followed by a list of options (e.g., /N=512), followed by a parameter list. The operation name specifies the main action of the operation and determines the syntax of the rest of the command. The list of options specifies variations on the default behavior of the operation. If the default behavior of the operation is satisfactory then no options are required. The parameter list identifies the objects on which the operation is to operate. Some commands take no parameters. For example, in the command:

```
Make/D/N=512 wave1, wave2, wave3
```

the operation name is "Make". The list of options is "/D/N=512". The parameter list is "wave1, wave2, wave3". An option such as "/D" or "/N=512" is sometimes termed a "flag".

You can use numeric expressions in the parameter list of an operation where Igor expects a numeric parameter, but in an operation option you need to parenthesize the expression. For example:

```
Variable val = 1.0
Make/N=(val) wave0, wave1
Make/N=(numpts(wave0)) wave2
```

The most common types of parameters are literal numbers or numeric expressions, literal strings or string expressions, names, and waves. In the example above, wave1 is a name parameter when passed to the Make operation. It is a wave parameter when passed to the Display and Smooth operations. A name parameter can refer to a wave that may or may not already exist whereas a wave parameter must refer to an existing wave.

See **Parameter Lists** on page IV-11 for general information that applies to all commands.

User-Defined Procedure Commands

For details on creating your own procedures, refer to chapters starting with IV-2.

User-defined procedure commands start with a macro, user function, or external function name followed by a list of parameters in parentheses. Here are a few examples:

```
MyFunction1(5.6, wave0, "igneous")
MyMacro1(1.2, 1/sqrt(ln(2)), "wave0")
MyMacro1(1.2, , )
MyMacro1( )
```

Macro and Function Parameters

As illustrated by the last two examples, you can invoke macros (but not functions) with one or more of the input parameters missing. When you do this, Igor puts up a dialog to allow you to enter the missing parameters. When you run a macro by choosing it from the Macros menu, Igor simply executes the macro with all of the parameters missing as in the last example. After you enter values in the dialog, the macro is executed with those parameters and the now-complete macro command is placed in the history. You can then

Chapter IV-1 — Working with Commands

fetch the command from the history, modify a parameter and then reexecute the command without having to go through the dialog.

You can add similar capabilities to user-defined functions using the **Prompt** (see page V-447) and **DoPrompt** (see page V-109) keywords. You can also use the **PauseForUser** (see page V-420) operation in a function to provide a more sophisticated way to get user input. WaveMetrics encourages programmers to use user-defined functions instead of macros.

There is an additional difference between functions and macros that you should be aware of. Functions can accept numeric, string and wave reference parameters. Macros can accept numeric and string parameters but can not accept literal wave names. For this reason, macros are written to accept waves in the form of strings containing the wave names. It's the difference between `wave0` and `"wave0"` in the first two examples above.

When you are using a package of procedures written by someone else you may need to determine what parameters a particular macro or function requires. If this is not documented you can easily inspect the source code by opening the procedure window and choosing the desired procedure from the pop-up menu at the bottom of the window.

Function Commands

A function is a routine that directly returns a numeric or string value. There are three classes of functions available to Igor users:

- Built-in
- External (XFUNCs)
- User-defined

Built-in numeric functions enjoy one advantage over external or user-defined functions: a few come in real and complex number types and Igor automatically picks the appropriate version depending on the current number type in an expression. External and user-defined functions must have different names when different types are needed. Generally, only real user and external functions need be provided.

For example, in the wave assignment:

```
wave1 = enoise(1)
```

if `wave1` is real then the function `enoise` returns a real value. If `wave1` is complex then `enoise` returns a complex value.

You can use a function as a parameter to another function, to an operation, to a macro or in an arithmetic or string expression so long as the data type returned by the function makes sense in the context in which you use it.

User-defined and external functions can also be used as commands by themselves. Use this to write a user function that has some purpose other than calculating a numeric value, such as displaying a graph or making new waves. Built-in functions cannot be used this way. For instance:

```
MyDisplayFunction(wave0)
```

External and user-defined functions can be used just like built-in functions. In addition, numeric functions can be used in curve fitting. See Chapter IV-3, **User-Defined Functions** and **Fitting to a User-Defined Function** on page III-168.

Most functions consist of a function name followed by a left parenthesis followed by a parameter list and followed by a right parenthesis. In the wave assignment shown at the beginning of this section, the function name is `enoise`. The parameter is 1. The parameter is enclosed by parentheses. In this example, the result from the function is assigned to a wave. It can also be assigned to a variable or printed:

```
K0 = enoise(1)
Print enoise(1)
```

User and external functions (but not built-in functions) can be executed on the command line or in other functions or macros without having to assign or print the result. This is useful when the point of the function is not its explicit result but rather its side effects.

Nearly all functions require parentheses even if the parameter list is empty. For example the function `date()` has no parameters but requires parentheses anyway. There are a few exceptions. For example the function `Pi` returns π and is used with no parentheses or parameters.

Igor's built-in functions are described in detail in Chapter V-1, **Igor Reference**.

Parameter Lists

Parameter lists are used for operations, functions, and macros and consist of one or more numbers, strings, keywords or names of Igor objects. The parameters in a parameter list must be separated with commas.

Expressions as Parameters

In an operation, function, or macro parameter list which has a numeric parameter you can always use a numeric expression instead of a literal number. A numeric expression is a legal combination of literal numbers, numeric variables, numeric functions, and numeric operators. For example, consider the command

```
SetScale x, 0, 6.283185, "v", wave1
```

which sets the X scaling for `wave1`. You could also write this as

```
SetScale x, 0, 2*PI, "v", wave1
```

Parentheses Required for /N=<expression>

Many operations accept flags of the form `/A=n` where A is some letter and n is some number. You can use a numeric expression for n but you must parenthesize the expression.

For example, both:

```
Make/N=512 wave1
```

```
Make/N=(2^9) wave1
```

are legal but this isn't:

```
Make/N=2^9 wave1
```

A variable name is a form of numeric expression. Thus, assuming `v1` is the name of a variable:

```
Make/N=(v1)
```

is legal, but

```
Make/N=v1
```

is not. This parenthesization is required only when you use a numeric expression in an operation flag.

String Expressions

A string expression can be used where Igor expects a string parameter. A string expression is a legal combination of literal strings, string variables, string functions and the string operator `+` which concatenates strings.

Setting Bit Parameters

A number of commands require that you specify a bit value to set certain parameters. In these instances you set a certain bit *number* by using a specific bit *value* in the command. The bit value is 2^n , where *n* is the bit number. So, to set bit 0 use a bit value of 1, to set bit 1 use a bit value of 2, etc.

For the example of the `TraceNameList` function the last parameter is a bit setting. To select normal traces you must set bit 0:

```
TraceNameList("",";",1)
```

and to select contour traces set bit 1:

```
TraceNameList("",";",2)
```

Most importantly, you can set multiple bits at one time by adding the bit values together. Thus, for `TraceNameList` you can select both normal (bit 0) and contour (bit 1) traces by using:

```
TraceNameList("",";",3)
```

See also **Using Bitwise Operators** on page IV-32.

Strings

Igor has a rich repertoire of string handling capabilities. See **Strings** on page V-7 for a complete list of Igor string functions. Many of the techniques described in this section will be of interest only to programmers.

Many Igor operations require *string* parameters. For example, to label a graph axis, you can use the `Label` operation:

```
Label left, "Volts"
```

Other Igor operations, such as `Make`, require *names* as parameters:

```
Make wave1
```

Using the string substitution technique, described in **String Substitution Using \$** on page IV-14, you can generate a name parameter by making a string containing the name and using the `$` operator:

```
String stringContainingName = "wave1"  
Make $stringContainingName
```

String Expressions

Wherever Igor requires a string parameter, you can use a string expression. A string expression can be:

- A literal string (`"Today is"`)
- The output of a string function (`date()`)
- An element of a text wave (`textWave0[3]`)
- Some combination of string expressions (`"Today is" + date()`)

In addition, you can derive a string expression by indexing into another string expression. For example,

```
Print ("Today is" + date())[0,4]
```

prints "Today".

A string variable can store the result of a string expression. For example:

```
String str1 = "Today is" + date()
```

A string variable can also be part of a string expression, as in:

```
Print "Hello. " + str1
```

Strings in Text Waves

A text wave contains an array of text strings. Each element of the wave can be treated using all of the available string manipulation techniques. In addition, text waves are commonly used to create category axes in bar charts. See **Text Waves** on page II-88 for further information.

There is a potential ambiguity with string indexing when the string is stored in a text wave. See **String Indexing** on page IV-13.

String Properties

Strings in Igor can be of unlimited length. There are no restrictions on the characters that can be stored in a string except for the null character (ASCII code 0). Storing a null in a string causes problems because the C functions that Igor uses internally to handle strings take null as an end-of-string flag.

Some Igor functions can take an empty string (`" "`, no space between the quotation marks) as a parameter.

Escape Characters in Strings

Igor treats the backslash character in a special way when reading literal (quoted) strings in a command line. The backslash is used to define something called an “escape sequence”. This just means that the backslash plus the next character or next few characters are treated like a different character — one you could not otherwise include in a quoted string. The escape sequences are:

```
\t      Tab character
\r      Return character
\n      Linefeed character
\'      The ' character
\"      The " character
\\      The \ character
\ddd    An arbitrary ASCII code (ddd is a 3 digit octal number)
```

For example, if you have a string variable called “fileName”, you could print it in the history area using:

```
fileName = "Test"
Printf "The file name is \"%s\"\\r", fileName
```

which prints

```
The file name is "Test"
```

In the Printf command line, \" embeds a double-quote character in the format string. If you omitted the backslash, the " would end the format string. The \\ specifies that you want a carriage return in the format string.

String Indexing

Indexing can extract a part of a string. This is done using a string expression followed by one or two numbers in brackets. The numbers are character positions. Zero is the character position of the first character; n-1 is the character position of the last character of an n character expression. For example, assume we create a string variable called s1 and assign a value to it as follows:

```
String s1="hello there"
```

h	e	l	l	o		t	h	e	r	e
0	1	2	3	4	5	6	7	8	9	10

Then,

```
Print s1[0,4]           prints  hello
Print s1[0,0]           prints  h
Print s1[0]             prints  h
Print s1[1]+s1[2]+s1[3] prints  ell
Print (s1+" jack")[6,15] prints  there jack
```

A string indexed with one number, such as s1[p], is a string with one character in it if p is in range (i.e. $0 \leq p \leq n-1$). s1[p] is a string with no characters in it if p is not in range. For example:

```
Print s1[0]             prints  h
Print s1[-1]            prints  (nothing)
Print s1[10]            prints  e
Print s1[11]            prints  (nothing)
```

A string indexed with two numbers, such as s1[p1,p2], contains all of the characters from s1[p1] to s1[p2]. For example:

```
Print s1[0,10]          prints  hello there
Print s1[-1,11]         prints  hello there
Print s1[-2,-1]         prints  (nothing)
```

Chapter IV-1 — Working with Commands

```
Print s1[11,12]           prints  (nothing)
Print s1[10,0]             prints  (nothing)
```

Because the syntax for string indexing is identical to the syntax for wave indexing, you have to be careful when using text waves. For example:

```
Make/T textWave0 = {"Red", "Green", "Blue"}
```

```
Print textWave0[1]         prints  Green
Print textWave0[1][1]      prints  Green
Print textWave0[1][1][1]   prints  Green
Print textWave0[1][1][1][1] prints  Green
Print textWave0[1][1][1][1][1] prints r
```

The first four examples print row 1 of column 0. Since waves may have up to four dimensions, the first four [1]'s act as dimension indices. The column, layer, and chunk indices were out of range and were clipped to a value of 0. Finally in the last example, we ran out of dimensions and got string indexing. **Warning:** Do not count on this behavior because future versions of Igor may support more than four dimensions.

The way to avoid the ambiguity between wave and string indexing is to use parentheses like so:

```
Print (textWave0[1])[1]    prints  r
```

String Assignment

You can assign values to string variables using string assignment. We have already seen the simplest case of this, assigning a literal string value to a string variable. You can also assign values to a subrange of a string variable, using string indexing. Once again, assume we create a string variable called s1 and assign a value to it as follows:

```
String s1="hello there"
```

Then,

```
s1[0,4]="hi";print s1      prints  hi there
s1[0,4]="greetings";print s1 prints  greetings there
s1[0,0]="j";print s1       prints  jello there
s1[0]="well ";print s1     prints  well hello there
s1[100000]=" jack";print s1 prints  hello there jack
s1[-100]="well ";print s1  prints  well hello there
```

When the s1[p1,p2]= syntax is used, the right-hand side of the string assignment *replaces* the subrange of the string variable identified by the left-hand side, after p1 and p2 are clipped to 0 to n.

When the s1[p]= syntax is used, the right-hand side of the string assignment *is inserted before* the character identified by p after p is limited to 0 to n.

The subrange assignment just described for string variables is not supported when a text wave is the destination. To assign a value to a range of a text wave element, you will need to create a temporary string variable. For example:

```
Make/O/T tw = {"Red", "Green", "Blue"}
String stmp= tw[1]
stmp[1,2]="XX"
tw[1]= stmp;

print tw[0],tw[1],tw[2]    prints  Red GXXen Blue
```

String Substitution Using \$

Wherever Igor expects the literal *name* of an operand, such as the name of a wave, you can instead provide a string expression preceded by the \$ character. The \$ character evaluates the string expression and *substitutes* that *value* as the *name* expected.

\$ is most often used when you write a macro which receives the name of a wave as a parameter. Here is a trivial example:

```
Macro DisplayWave(w)
    String w          // name of the wave

    Display $w
End
```

We would invoke this macro as follows:

```
DisplayWave("wave0")
```

We use \$ because we need a wave name but we have a string containing a wave name. If we executed:

```
Display w
```

Igor would try to act on a wave whose name is w, not on a wave whose name is wave0.

String substitution is capable of converting a string expression to a *single* name. It can not handle multiple names. For example, the following will *not* work:

```
String list = "wave0;wave1;wave2"
Display $list
```

See **Processing Lists of Waves** on page IV-144 for ways to accomplish this.

The remainder of this section discusses ambiguities when using string substitution in assignment statements in the command line or in a macro. This is somewhat academic because modern Igor programming is done with user-defined functions. In user-defined functions, the ambiguity is removed through the use of “wave references” (described in **Accessing Waves in Functions** on page IV-57).

There is one case in which string substitution does not work as you might expect. Consider this example:

```
wave2 = $str1 + 3
```

where str1 contains the string “wave1”. You might expect that this would cause Igor to set wave2 equal to the sum of wave1 and 3. Instead, it generates an “expected string expression” error. The reason is that Igor tries to concatenate str1 and 3 *before* doing the substitution implied by \$. The + operator is also used to concatenate two string expressions, and it has higher precedence than the \$ operator. Since str1 is a string but 3 is not, Igor cannot do the concatenation.

You can get around this problem by changing this wave assignment to one of the following:

```
wave2 = 3 + $str1
wave2 = ($str1) + 3
```

Both of these accomplish the desired effect of setting wave2 equal to the sum of wave1 and 3. Similarly,

```
wave2 = $str1 + $str2    // Igor sees "$ (str1 + $str2)"
```

generates the same “expected string expression” error. The reason is that Igor is trying to concatenate str1 and \$str2. \$str2 is a name, not a string. The solution is:

```
wave2 = ($str1) + ($str2) // sets wave2 to sum of two named waves
```

Another situation arises when using the \$ operator and [. The [symbol can be used for either point indexing into a wave, or character indexing into a string. The commands

```
String wvName = "wave0"
$wvName[1,2] = wave1[p]    // sets two values in wave named "wave0"
```

are interpreted to mean that points 1 and 2 of wave0 are set values from wave1.

If you intended “\$wvName[1,2] = wave1” to mean that a wave whose name comes from characters 1 and 2 of the wvName string (“av”) has all of its values set from wave1, you must use parenthesis:

```
$(wvName[1,2]) = wave1    // sets all values of wave named "av"
```

String Utility Functions

WaveMetrics provides a number of handy utility functions for dealing with strings. To see a list of the built-in string functions, open the Igor Help Browser Command Help tab and then choose String from the pop-up menu of function categories. See also the string utility procedure files provided by WaveMetrics in the WaveMetrics Procedures:Utilities:String Utilities folder.

Special Cases

This section documents some techniques that were devised to handle certain specialized situations that arise with respect to Igor's command language.

Instance Notation

There is a problem that occurs when you have multiple instances of the same wave in a graph or multiple instances of the same object in a layout. For example, assume you want to graph yWave versus xWave0, xWave1, and xWave2. To do this, you need to execute:

```
Display yWave vs xWave0
AppendToGraph yWave vs xWave1
AppendToGraph yWave vs xWave2
```

The result is a graph in which yWave occurs three times. Now, if you try to remove or modify yWave using:

```
RemoveFromGraph yWave
```

or

```
ModifyGraph lsize(yWave)=2
```

Igor will always remove or modify the first instance of yWave.

Instance notation provides a way for you to specify a particular instance of a particular wave. In our example, the command

```
RemoveFromGraph yWave#2
```

will remove instance number 2 of yWave and

```
ModifyGraph lsize(yWave#2)=2
```

will modify instance number 2 of yWave. Instance numbers start from zero so "yWave" is equivalent to "yWave#0". Instance number 2 is the instance of yWave plotted versus xWave2 in our example.

Where necessary to avoid ambiguity, Igor operation dialogs (e.g., Modify Trace Appearance) automatically use instance notation. Operations that accept trace names (e.g., ModifyGraph) or layout object names (e.g., ModifyObject) accept instance notation.

A graph can also display multiple waves with the same name if the waves reside in different datafolders. Instance notation applies to this case also.

Instance Notation and \$

The \$ operator can be used with instance notation. The # symbol may be either inside the string operand or may be outside. For example "\$wave0#1" or "\$wave0"#1. However, because the # symbol may be inside the string, the string must be parsed by Igor. Consequently, unlike other uses of \$, the wave name portion must be surrounded by single quotes if liberal names are used. For example, suppose you have a wave with the liberal name of 'ww#1' plotted twice. The first instance would be "\$ 'ww#1' " and the second "\$ 'ww#1' #1" whereas "\$ww#1" would reference the second instance of the wave ww.

Object Indexing

The ModifyGraph, ModifyTable and ModifyLayout operations, used to modify graphs, tables and page layouts, each support another method of identifying the object to modify. This method, object indexing, is used to generate style macros (see **Graph Style Macros** on page II-280). You may also find it handy in other situations.

Normally, you need to know the name of the object that you want to modify. For example, assume that we have a graph with three traces in it and we want to set the traces' markers from a procedure. We can write:

```
ModifyGraph marker(wave0)=1, marker(wave1)=2, marker(wave2)=3
```

Because it uses the names of particular traces, this command is specific to a particular graph. What do we do if we want to write a command that will set the markers of three traces in *any* graph, regardless of the names of the traces? This is where object indexing comes in.

Using object indexing, we can write:

```
ModifyGraph marker[0]=1, marker[1]=2, marker[2]=3
```

This command sets the markers for the first three traces in a graph, no matter what their names are.

Indexes start from zero. For graphs, the object index refers to traces starting from the first trace placed in the graph. For tables the index refers to columns from left to right. For page layouts, the index refers to objects starting from the first object placed in the layout.

/Z Flag

The `ModifyGraph marker` command above works fine if you know that there *are* three waves in the graph. It will, however, generate an error if you use it on a graph with fewer than 3 waves. The `ModifyGraph` operation supports a flag that can be used to handle this:

```
ModifyGraph/Z marker[0]=1, marker[1]=2, marker[2]=3
```

The `/Z` flag ignores errors if the command tries to modify an object that doesn't exist. The `/Z` flag works with the `SetAxis` and `Label` operations as well as with the `ModifyGraph`, `ModifyTable` and `ModifyLayout` operations. Like object indexing, the `/Z` flag is primarily of use in creating style macros, which is done automatically, but it may come in handy for other uses.

Macros and Functions	21
Scanning and Compiling Procedures.....	22
Indentation Conventions	22
What's Next	23

Overview

You can perform powerful data manipulation and analysis interactively using Igor's dialogs and the command line. However, if you want to automate common tasks or create custom numerical operations then you need to use procedures. You can write them yourself, use procedures supplied by WaveMetrics, or find someone else who has written procedures you can use. Even if you don't write procedures from scratch, it is useful to know enough about Igor programming to be able to understand code written by others.

Programming in Igor entails creating procedures by entering text in a procedure window. After entering a procedure, you can execute it via the command line, by choosing an item from a menu, or using a button in a control panel.

The bulk of the text in a procedure window falls into one of the following categories:

- Pragmas, which send instructions from the programmer to the Igor compiler
- Include statements, which open other procedure files
- Constants, which define symbols used in functions
- Structure definitions, which can be used in functions
- Proc Pictures, which define images used in control panels, graphs, and layouts
- Menu definitions, which add menu items or entire menus to Igor
- Functions — compiled code which is used for nearly all Igor programming
- Macros — interpreted code which, for the most part, is obsolete

Functions are written in Igor's programming language. Like conventional procedural languages such as C or Pascal, Igor's language includes:

- Data storage elements (variables, strings, waves)
- Assignment statements
- Flow control (conditionals and loops)
- Calls to built-in and external operations and functions
- Ability to define and call subroutines

Igor programming is easier than conventional programming because it is much more interactive — you can write a routine and test it right away. It is designed for interactive use within Igor rather than for creating stand-alone programs.

Organizing Procedures

Procedures can be stored in the built-in Procedure window or in separate auxiliary procedure files. Chapter III-13, **Procedure Windows**, explains how to edit the Procedure window and how to create auxiliary procedure files.

At first you will find it convenient to do all of your Igor programming in the built-in Procedure window. In the long run, however, it will be useful to organize your procedures into categories so that you can easily find and access general-purpose procedures and keep them separate from special-case procedures.

This table shows how we categorize procedures and how we store and access the different categories.

Category	What	Where	How
Experiment Procedures	These are specific to a single Igor experiment. They include procedures you write as well as window recreation macros created automatically when you close a graph, table, layout, control panel, or XOP target window (e.g., surface plot).	Usually experiment procedures are stored in the built-in Procedure window. You can optionally create additional procedure windows in a particular experiment but this is usually not needed.	You create an experiment procedure by typing in the built-in Procedure window.
Utility Procedures	These are general-purpose and potentially useful for any Igor experiment. WaveMetrics supplies utility procedures in the WaveMetrics Procedures folder. You can also write your own procedures or get them from colleagues.	WaveMetrics-supplied utility procedure files are stored in the WaveMetrics Procedures folder. Utility procedure files that you or other Igor users create should be stored in your own folder, outside the Igor Pro Folder. Place an alias or shortcut for your folder in the User Procedures folder.	Use an include statement to use a WaveMetrics or user utility procedure file. Include statements are described in The Include Statement on page IV-119.
Global Procedures	These are procedures that you want to be available from all experiments.	Store global procedure files in your own folder, outside the Igor Pro Folder. Place an alias or shortcut for your folder in the Igor Procedures folder.	Igor automatically opens any procedure file in the Igor Procedures folder or referenced by an alias or shortcut in the Igor Procedures folder, and leaves it open in all experiments.

Following this scheme, you will know where to put procedure files that you get from colleagues and where to look for them when you need them.

Utility and global procedures should be general-purpose so that they can be used from any experiment. Thus, they should not rely on specific waves, global variables, global strings, specific windows or any other objects specific to a particular experiment. See **Writing General-Purpose Procedures** on page IV-120 for further guidelines.

After they are debugged and thoroughly tested, you may want to share your procedures with other Igor users. If so, contact WaveMetrics for help in publicizing and distributing them.

WaveMetrics Procedure Files

WaveMetrics has created a large number of utility procedure files that you can use as building blocks. These files are stored in the WaveMetrics Procedures folder. They are described in the WM Procedures Index help file, which you can access through the Windows→Help Windows menu.

You access WaveMetrics procedure files using include statements. Include statements are explained under **The Include Statement** on page IV-119.

Using the Igor Help Browser, you can search the WaveMetrics Procedures folder to find examples of particular programming techniques.

Macros and Functions

There are two kinds of Igor procedures: **macros** and **functions**. They use similar syntax. The main difference between them is that Igor compiles user functions but interprets macros.

Because functions are compiled, they are dramatically faster than macros. Compilation also allows Igor to detect errors in functions when you write the function, whereas errors in macros are detected only when they are executed.

Macros are a legacy of Igor's early days. With rare exceptions, **all new programming should use functions**, not macros. To simplify the presentation of Igor programming, most discussion of macros is segregated into Chapter IV-4, **Macros**.

Scanning and Compiling Procedures

When you modify text in a procedure window, Igor must process it before you can execute any procedures. There are two parts to the processing: scanning and function compilation. In the scanning step, Igor finds out what procedures exist in the window. In the compilation step, Igor's function compiler converts the function text into low-level instructions for later execution.

During scanning, Igor makes the cursor look like scrolling text. 

During compilation, Igor makes the cursor look like a meat grinder (text in, bits out). 

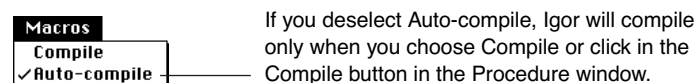

For the sake of brevity, we use the term “compile” to mean “scan and compile” except when we are specifically pointing out the distinction between these two steps.

You can *explicitly* compile the procedures using the Compile button in the Procedure window or the Compile item in the Macros menu.

By default, Igor *automatically* compiles the procedure text at appropriate times. For example, if you type in the Procedure window and then hide it by clicking in the close button, Igor will automatically compile.

If you have many procedures that take long to compile, you may want to turn auto-compiling off using the Macros menu.

When Auto-compile is deselected, Igor compiles only when you explicitly request it. Igor will still scan the procedures when it needs to know what macros and functions exist.

Indentation Conventions

We use indentation to indicate the structure of a procedure.

```

Function Example()
    <Input parameter declarations>
    <Local variable declarations>

    if (condition)
        <true part>
    else
        <false part>
    endif

    do
        <loop body>
    while (condition)
End
  
```

The body of the function is indented by one tab.

Indentation clearly shows what is executed if the condition is true and what is executed if it is false.

The body of the loop is indented by one tab.

The structural keywords, shown in bold here, control the flow of the procedure. The purpose of the indentation is to make the structure of the procedure apparent by showing which lines are within which struc-

tural keywords. Matching keywords are at the same level of indentation and all lines within those keywords are indented by one tab.

The Edit menu contains aids for maintaining or adjusting indentation. You can select multiple lines and choose Indent Left or Indent Right. You can have Igor automatically adjust the indentation of a procedure by selecting the whole procedure or a subset and then choosing Adjust Indentation.

Igor does not require that you use indentation but we recommend it for readability.

What's Next

The next chapter covers the core of Igor programming — writing user-defined functions.

Chapter IV-4, **Macros**, explains macros. Because new programming does not use macros, that chapter is mostly of use for understanding old Igor code.

Chapter IV-5, **User-Defined Menus**, explains user-defined menus. It explains how you can add menu items to existing Igor menus and create entire new menus of your own.

Chapter IV-6, **Interacting with the User**, explains other methods of interacting with the user, including the use of dialogs, control panels, and cursors.

Chapter IV-7, **Programming Techniques**, covers an assortment of programming topics. An especially important one is the use of the include statement, which you use to build procedures on top of existing procedures.

Chapter IV-8, **Debugging**, covers debugging using Igor's symbolic debugger.

Chapter IV-9, **Dependencies**, covers dependencies — a way to tie a variable or wave to a formula.

Chapter IV-10, **Advanced Programming**, covers advanced topics, such as communicating with other programs, doing FTP transfers, doing data acquisition, and creating a background task.

Overview

Most of Igor programming consists of writing user-defined functions.

A function has zero or more numeric, string and wave parameters. You can use local variables to store intermediate results. The function body consists of Igor operations, assignment statements, flow control statements, and calls to other functions.

A function can return a numeric or string result. It can also have a side-effect, such as creating a wave or creating a graph.

Before we dive into the technical details, here is an informal look at some simple examples.

```
Function Hypotenuse(side1, side2)
    Variable side1, side2

    Variable hyp
    hyp = sqrt(side1^2 + side2^2)

    return hyp
End
```

The Hypotenuse function takes two numeric parameters and returns a numeric result. “hyp” is a local variable and sqrt is a built-in function. You could test Hypotenuse by executing the following statement in the command line:

```
Print Hypotenuse(3, 4)
```

Now let’s look at a function that deals with text strings.

```
Function/S FirstStr(str1, str2)
    String str1, str2

    String result

    if (CmpStr(str1, str2) < 0)
        result = str1
    else
        result = str2
    endif

    return result
End
```

The FirstStr function takes two string parameters and returns the string that is first in alphabetical order. CmpStr is a built-in function. You could test FirstStr by executing the following statement in the command line:

```
Print FirstStr("ABC", "BCD")
```

Now a function that deals with waves.

```
Function CreateRatioOfWaves(w1, w2, nameOfOutputWave)
    WAVE w1, w2
    String nameOfOutputWave

    Duplicate/O w1, $nameOfOutputWave
    WAVE wOut = $nameOfOutputWave
    wOut = w1 / w2
End
```

The CreateRatioOfWaves function takes two wave parameters and a string parameter. The string is the name to use for a new wave, created by duplicating one of the input waves. The “WAVE wOut” statement creates a wave reference for use in the following assignment statement. This function has no direct result (no return statement) but has the side-effect of creating a new wave.

Chapter IV-3 — User-Defined Functions

Here are some commands to test CreateRatioOfWaves:

```
Make test1 = {1, 2, 3}, test2 = {2, 3, 4}
CreateRatioOfWaves(test1, test2, "ratio")
Edit test1, test2, ratio
```

Function Syntax

The basic syntax of a function is:

```
Function <Name> (<Parameter list> [<Optional Parameters>]) [:<Subtype>]
    <Parameter declarations>

    <Local variable declarations>

    <Body code>

    <Return statement>
End
```

Here is an example:

```
Function Hypotenuse(side1, side2)
    Variable side1, side2          // Parameter declaration

    Variable hyp                   // Local variable declaration

    hyp = sqrt( side1^2 + side2^2 ) // Body code

    return hyp                     // Return statement
End
```

You could test this function from the command line using one of these commands:

```
Print Hypotenuse(3,4)
Variable/G result = Hypotenuse(3,4); Print result
```

As shown above, the function returns a real, numeric result. The Function keyword can be followed by a flag that specifies a different result type.

Flag	Return Value Type
/C	Complex number
/S	String
/D	Double precision number (obsolete)

The /D flag is obsolete because all calculations are now performed in double precision. However, it is still permitted.

The Function Name

The names of functions must follow the standard Igor naming conventions. Names can consist of up to 31 characters. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Function ButtonProc(ctrlName) : ButtonControl
    String ctrlName

    Beep
End
```

Here, “ : ButtonControl” identifies a function intended to be called when a user-defined button control is clicked. Because of the subtype, this function is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-149 for details.

The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. There is no limit on the number of parameters.

All parameters must be declared immediately after the function declaration.

The parameter declaration must declare the type of each parameter using the keywords **Variable**, **String**, or **WAVE**.

If a parameter is a complex number, it must be declared **Variable/C**.

If it is a complex wave, it must be declared **WAVE/C**.

If it is a text wave, it must be declared **WAVE/T**.

Variable and string parameters are usually passed to a subroutine *by value* but can also be passed *by reference*. For an explanation of these terms, see **How Parameters Work** on page IV-44.

Optional Parameters

Following the list of required function input parameters, you can also specify a list of optional input parameters by enclosing the parameter names in brackets. You can supply any number of optional parameter values when calling the function by using the *ParamName=Value* syntax. Optional parameters may be of any valid data type. There is no limit on the number of parameters.

All optional parameters must be declared immediately after the function declaration. As with all other variables, optional parameters are initialized to zero. You must use the **ParamIsDefault** function to determine if a particular optional parameter was supplied in the function call.

See **Using Optional Parameters** on page IV-46 for an example.

Local Variable Declarations

The parameter declarations are followed by the local variable declarations if the procedure uses local variables. Local variables exist only during the execution of the procedure. They can be numeric or string and are declared using the **Variable** or **String** keywords. They can optionally be initialized. Here is an example:

```
Function Example(p1)
    Variable p1

    // Here are the local variables
    Variable v1, v2
    Variable v3=0
    Variable/C cv1=cplx(0,0)
    String s1="test", s2="test2"

    <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero. Local string variables are initialized with a null value such that, if you try to use the string before you store a value in it, Igor will report an error.

The name of a local variable is allowed to conflict with other names in Igor although they must be unique within the function. Clearly if you create a local variable named “sin” then you will be unable to use Igor’s built-in sin function within the function.

You can declare local variables in the body code section of a function as well as in the local variable section.

Chapter IV-3 — User-Defined Functions

As of Igor Pro 5, you can define structures and use them as local variables in functions. Structures are defined outside of function definitions and are instantiated as local variables using the **STRUCT** keyword as described in **Structures in Functions** on page IV-61.

Body Code

This table shows what can appear in body code of a function.

What	Allowed in Functions?	Comment
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes, with a few exceptions.	See Operations in Functions on page IV-71 for exceptions.
Calls to user functions	Yes	
Calls to macros	No	
External functions	Yes	
External operations	Yes, with exceptions.	

As of Igor Pro 5, external operations can be designed to be directly callable from user-defined functions. External operations implemented by old XOPs can not be called directly.

The **Execute** operation provides a way to work around the limitation on what can be called from user functions. See **The Execute Operation** on page IV-147.

The Return Statement

A return statement often appears at the end of a function, but it can appear anywhere in the function body. You can also have more than one return statement.

The return statement immediately stops executing the function and returns a value to the calling function. If the function is declared as a string function (Function/S), then the return statement must return a string. Otherwise it must return a number.

If there is no return statement or if a function ends without hitting a return statement then the function returns the value NaN (Not a Number) for numeric functions and null for string functions. If the calling function attempts to use the null value, Igor will report an error.

Conditional Statements in Functions

Igor Pro supports two basic forms of conditional statements: if-else-endif and if-elseif-endif statements. Igor also supports multiway branching with switch and strswitch statements.

If-Else-Endif

The form of the if-else-endif structure is

```
if ( <expression> )
    <TRUE part>
else
    <FALSE part>
endif
```

<expression> is a numeric expression that is considered TRUE if it evaluates to any nonzero number and FALSE if it evaluates to zero. The TRUE part and the FALSE part may consist of any number of lines. If the expression evaluates to TRUE, only the TRUE part is executed and the FALSE part is skipped. If the expression evaluates to FALSE, only the FALSE part is executed and the true part is skipped. After the TRUE part or FALSE part code is executed, execution will continue with any code immediately following the if-else-endif statement.

The keyword “else” and the FALSE part may be omitted to give a simple conditional:

```
if ( <expression> )
    <TRUE part>
endif
```

Because Igor is line-oriented, you may not put the `if`, `else` and `endif` keywords all on the same line. They must each be in separate lines with no other code.

If-Elseif-Endif

The if-elseif-endif statement provides a means for creating nested if structures. It has the form:

```
if ( <expression1> )
    <TRUE part 1>
elseif ( <expression2> )
    <TRUE part 2>
[else
    <FALSE part>]
endif
```

These statements follow similar rules as for if-else-endif statements. When any expression evaluates as TRUE (nonzero) the code immediately following the expression will be executed. If all expressions evaluate as FALSE (zero) and there is an else clause, then the statements following the else keyword will be executed. Once any code in a TRUE part or the FALSE part is executed, execution will continue with any code immediately following the if-elseif-endif statement.

Comparisons

The relational comparison operators are used in numeric conditional expressions.

Symbol	Meaning	Symbol	Meaning
==	equal	<=	less than or equal
!=	not-equal	>	greater than
<	less than	>=	greater than or equal

These operators return 1 for TRUE and 0 for FALSE.

The comparison operators work with numeric operands only. To do comparisons with string operands, use the **cmpstr** function.

Comparison operators are usually used in conditional structures but can also be used in arithmetic expressions. For example:

```
wave0 = wave0 * (wave0 < 0)
```

This clips all positive values in wave0 to zero.

See also **Example: Comparison Operators and Wave Synthesis** on page II-84.

Bitwise and Logical Operators

The bitwise and logical operators are also used in conditional expressions.

Symbol	Meaning	Symbol	Meaning
~	Bitwise complement	!	Logical NOT
&	Bitwise AND	&&	Logical AND
	Bitwise OR		Logical OR

Chapter IV-3 — User-Defined Functions

The precedence of operators is shown in the table under **Operators** on page IV-5. In the absence of parentheses, an operator with higher precedence (higher in the table) is executed before an operator with lower precedence.

Because the precedence of the arithmetic operators is higher than the precedence of the comparison operators, you can write the following without parentheses:

```
if (a+b != c+d)
    Print "a+b is not equal to c+d"
endif
```

Because the precedence of the comparison operators is higher than the precedence of the logical OR operator, you can write the following without parentheses:

```
if (a==b || c==d)
    Print "Either a equals b or c equals d"
endif
```

For operators with the same precedence, there is no guaranteed order of execution and you must use parentheses to be sure of what will be executed. For example:

```
if ((a&b) != (c&d))
    Print "a ANDED with b is not equal to c ANDED with d"
endif
```

See **Operators** on page IV-5 for more discussion of operators.

Using Bitwise Operators

The bitwise operators are used to test, set, and clear bits. This makes sense only when you are dealing with integer operands.

Bit Action	Operation
Test	AND operator (&)
Set	OR operator ()
Clear	Bitwise complement operator (~) followed by the bitwise AND operator (&)
Shift left	Multiply by powers of 2
Shift right	Divide by powers of 2

This function illustrates various bit manipulation techniques.

```
Function DemoBitManipulation(vIn)
    Variable vIn

    vIn = trunc(vIn)                // Makes sense with integers only
    Printf "Original value: %d\r", vIn

    Variable vOut

    if ((vIn & 2^3) != 0)           // Test if bit 3 is set
        Print "Bit 3 is set"
    else
        Print "Bit 3 is cleared"
    endif

    vOut = vIn | (2^3)              // Set bit 3
    Printf "Set bit 3: %d\r", vOut

    vOut = vIn & ~(2^3)             // Clear bit 3
    Printf "Clear bit 3: %d\r", vOut

    vOut = vIn * (2^3)              // Shift three bits left
    Printf "Shift three bits left: %d\r", vOut
```

```

    vOut = vIn / (2^3)           // Shift three bits right
    Printf "Shift three bits right: %d\r", vOut
End

```

For a simple demonstration, try this function passing 1 as the parameter.

In this example, 2^3 evaluates to 8 which is a value with only bit 3 set. In a real application, it is a good idea to define a constant that indicates the significance of the bit. These two statements are equivalent:

```

Constant kSystemReadyMask 8      // 8 specified in decimal notation
Constant kSystemReadyMask 0x08   // 8 specified in hexadecimal notation

```

Switch Statements

The switch construct can sometimes be used to simplify complicated flow control. It chooses one of several execution paths depending on a particular value.

Instead of a single form of switch statement, as is the case in C, Igor has two types: *switch* for numeric expressions and *strswitch* for string expressions. The basic syntax of these switch statements is as follows:

```

switch(<numeric expression>)      // numeric switch
    case <literal number or numeric constant>:
        <code>
        [break]
    case <literal number or numeric constant>:
        <code>
        [break]
    . . .
    [default:
        <code>]
endswitch

strswitch(<string expression>)    // string switch
    case <literal string or string constant>:
        <code>
        [break]
    case <literal string or string constant>:
        <code>
        [break]
    . . .
    [default:
        <code>]
endswitch

```

The switch numeric or string expression is evaluated and execution proceeds with the code following the matching case label. When none of the case labels match, execution will continue at the default label, if it is present, or otherwise the switch will exit with no action taken.

All of the case labels must be numeric or string constant expressions and they must all have unique values within the switch statement. The constant expressions can either be literal values or they must be declared using the constant and strconstant keywords for numeric and string switches, respectively. For more about constants, see **Constants** on page IV-38.

Execution proceeds within each case until a break statement is encountered or the endswitch is reached. The break statement explicitly exits the switch construct. Usually, you will put a break statement at the end of each case. If you omit the break statement, execution continues with the next case label. Do this when you want to execute a single action for more than one switch value.

The following examples illustrate how switch constructs can be used in Igor:

```
Constant kThree=3
StrConstant ksHow="how"

Function NumericSwitch(a)
    Variable a

    switch(a)                                // numeric switch
        case 1:
            print "a is 1"
            break
        case 2:
            print "a is 2"
            break
        case kThree:
        case 4:
            print "a is 3 or 4"
            break
        default:
            print "a is none of those"
            break
    endswitch
End

Function StringSwitch(a)
    String a

    strswitch(a)                            // string switch
        case "hello":
            print "a is hello"
            break
        case ksHow:
            print "a is how"
            break
        case "are":
        case "you":
            print "a is are or you"
            break
        default:
            print "a is none of those"
            break
    endswitch
End
```

Loops

Igor implements two basic types of looping structures: do-while and for loops. The do-while loop iterates through the loop code and tests an exit condition at the end of each iteration. The for loop is more complex; the beginning of a for loop includes expressions for initializing and updating variables as well as testing the loop's exit condition at the start of each iteration.

Do-While Loop

The form of the do-while loop structure is:

```
do
    <loop body>
while(<expression>)
```

This loop runs until the expression evaluates to zero or until a break statement is executed.

This example will always execute the body of the loop at least once, like the do-while loop in C.

```
Function Test(lim)
    Variable lim    // We use this parameter as the loop limit.
```

```
Variable sum=0
Variable i=0      // We use i as the loop variable.
do
    sum += i      // This is the body; equivalent to sum=sum+i.
    i += 1        // Increment the loop variable.
while(i < lim)
return sum
End
```

Nested Do-While Loops

A nested loop is a loop within a loop. Here is an example:

```
Function NestedLoopTest(numOuterLoops, numInnerLoops)
    Variable numOuterLoops, numInnerLoops

    Variable i, j
    i = 0
    do
        j = 0
        do
            <inner loop body>
            j += 1
            while (j < numInnerLoops)
                i += 1
        while (i < numOuterLoops)
    End
```

While Loop

This fragment will execute the body of the loop zero or more times, like the while loop in C.

```
do
    if (i > lim)
        break      // This breaks out of the loop.
    endif
    <loop body>
    i += 1
while(1)           // This would loop forever without the break.
...               // Execution continues here after the break.
```

In this example, the loop increment is 1 but it can be any value.

For Loop

The basic syntax of a for loop is:

```
for(<initialize>;<continue test>;<update>)
    <loop body>
endfor
```

Here is a simple example:

```
Function Example1()
    Variable i

    for(i=0;i<5;i+=1)
        print i
    endfor
End
```

The beginning of a for loop consists of three semicolon-separated expressions. The first is usually an assignment statement that initializes one or more variables. The second is a conditional expression used to determine if the loop should be terminated — if true, nonzero, the loop is executed; if false, zero, the loop terminates. The third expression usually updates one or more loop variables.

Chapter IV-3 — User-Defined Functions

When a for loop executes, the initialization expression is evaluated only once at the beginning. Then, for each iteration of the loop, the continuation test is evaluated at the start of every iteration, terminating the loop if needed. The third expression is evaluated at the end of the iteration and usually increments the loop variable.

All three expressions in a for statement are optional and can be omitted independent of the others; only the two semicolons are required. The expressions can consist of multiple assignments, which must be separated by commas.

In addition to the test expression, for loops may also be terminated by break or return statements within the body of the loop. A continue statement executed within the loop skips the remaining body code and execution continues with the loop's update expression.

Here is a more complex example:

```
Function Example2()
    Variable i,j

    for(i=0,j=10; ;i+=1,j*=2)
        if( i==2 )
            continue
        endif
        Print i,j
        if( i==5 )
            break
        endif
    endfor
End
```

Break Statement

A break statement terminates execution of do-while loops, for loops, and switch statements. The break statement continues execution with the statement after the *enclosing* loop's while, endfor, or endswitch statement. A nested do-while loop example demonstrates this:

```
...
Variable i=0, j

do                                // Starts outer loop.
    if (i > numOuterLoops)
        break                    // Break #1, exits from outer loop.
    endif
    j = 0
    do                            // Start inner loop.
        if (j > numInnerLoops)
            break                // Break #2, exits from inner loop only.
        endif
        j += 1
    while (1)                    // Ends inner loop.
    ...                          // Execution continues here from break #2.
    i += 1
while (1)                        // Ends outer loop.
...                              // Execution continues here from break #1.
```

Continue Statement

The continue statement can be used in do-while and for loops to short-circuit the loop and return execution back to the top of the loop. When Igor encounters a continue statement during execution, none of the code following the continue statement is executed during that iteration.

Flow Control for Aborts

Igor Pro includes a specialized flow control construct and keywords that you can use to test for and respond to abort conditions. The `AbortOnRTE` and `AbortOnValue` keywords can be used to trigger aborts, and the `try-catch-endtry` construct can be used to control program execution when aborts occur. These are advanced techniques. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

AbortOnRTE Keyword

The `AbortOnRTE` keyword can be used to raise an abort whenever a runtime error occurs. Use `AbortOnRTE` immediately after (on the same line preceded by a semicolon) a command or on a line following a sequence of commands for which you wish to catch a runtime error.

See **AbortOnRTE** on page V-12 for further details. For a usage example see **try-catch-endtry Example** on page IV-37.

AbortOnValue Keyword

The `AbortOnValue` keyword can be used to abort function execution when a specified abort condition is satisfied. When `AbortOnValue` triggers an abort, it can also return a numeric abort code that you can use to characterize the cause.

`AbortOnValue` is a low overhead, short-hand replacement for an

```
if (abortTest)
    Abort
endif
```

code block that you would normally use in a procedure to test for an abort condition.

See **AbortOnValue** on page V-12 for further details. For a usage example see **try-catch-endtry Example** on page IV-37.

try-catch-endtry Flow Control

The `try-catch-entry` flow control construct has the following syntax:

```
try
    <possible abort code>
catch
    <code to handle abort>
endtry
```

The `try-catch-entry` flow control construct can be used to catch and respond to abort conditions in user functions. Code within the `try-catch` area tests for abort conditions and when the first abort condition is satisfied, execution will immediately jump to code within the `catch-endtry` area where execution proceeds with code to handle the abort condition. Normal flow (no aborts) will skip past all code within the `catch-endtry` area.

When an abort occurs within the `try-catch` area, the construct returns a numeric code in the `V_AbortCode` variable, which provides information about the cause of the abort.

See **try-catch-endtry** on page V-637 for further details.

try-catch-endtry Example

The following example demonstrates how abort flow control may be used. Copy the code to your Procedure window and execute the `foo` function with 0 to 6 as input parameters.

```
Function foo(a)
    Variable a

    print "A"
    try
```

```
print "B1"
AbortOnValue a==1 || a==2,33
print "B2"
bar(a)
print "B3"
try
    print "C1"
    if( a==4 || a==5 )
        Make $" "; AbortOnRTE
    endif
    Print "C2"
catch
    Print "D1"
    // will be runtime error so pass along to outer catch
    AbortOnValue a==5, V_AbortCode
    Print "D2"
endtry
Print "B4"
if( a==6 )
    do
        while(1)
        endif
    Print "B5"
catch
    print "Abort code= ", V_AbortCode
    if( V_AbortCode == -4 )
        Print "Runtime error= ", GetRTEError(1)
    endif
    if( a==1 )
        abort "Aborting again"
    endif
    Print "E"
endtry
print "F"
End

Function bar(b)
    Variable b

    Print "Bar A"
    AbortOnValue b==3,99
    Print "Bar B"
End
```

Constants

You can define named numeric and string constants in Igor procedure files and use them in the body of user-defined functions.

Constants are defined in procedure files using following syntax:

```
Constant <name1> = <literal number> [, <name2> = <literal number>]
StrConstant <name1> = <literal string> [, <name2> = <literal string>]
```

For example:

```
Constant kIgorStartYear=1989,kIgorEndYear=2020
StrConstant ksPlatformMac="Macintosh",ksPlatformWin="Windows"
```

```
Function Test1()
    Variable v1 = kIgorStartYear
    String s1 = ksPlatformMac
```

```
Print v1, s1  
End
```

Constants declared like this are public and can be used in any function in any procedure file. A typical use would be to define constants in a utility procedure file that could be used from other procedure files as parameters to the utility routines. Be sure to use precise names to avoid conflicts with public constants declared in other procedure files.

If you are defining constants for use in a single procedure file, for example to improve readability or make the procedures more maintainable, you should use the `static` keyword (see **Static** on page V-533 for details) to limit the scope to the given procedure file.

```
static Constant kStart=1989,kEnd=2020  
static StrConstant ksMac="Macintosh",ksWin="Windows"
```

We suggest that you use the “k” prefix for numeric constants and the “ks” prefix for string constants. This makes it immediately clear that a particular keyword is a constant.

Names for numeric and string constants are allowed to conflict with all other names. Duplicate constants of a given type are not allowed (except static in different files and when used with the override keyword). The only true conflict is with variable names and with certain built-in functions that do not take parameters such as `pi`. Variable names (including local variable names, waves, NVARs, and SVARs) override constants, but constants override functions such as `pi`.

Pragmas

A pragma is a statement in a procedure file that sets a compiler mode or passes other information from the programmer to Igor. The form of a pragma statement is:

```
#pragma keyword [= parameter]
```

The pragma statement must be flush against the left margin of the procedure window, with no indentation.

Currently, Igor supports the following pragmas:

```
#pragma rtGlobals = value  
#pragma version = versionNumber  
#pragma IgorVersion = versionNumber  
#pragma ModuleName = name
```

The effect of a pragma statement lasts until the end of the procedure file that contains it.

The rtGlobals Pragma

The `rtGlobals` pragma controls how the Igor compiler treats references to global variables and waves. Igor Pro 3 introduced a new way of referencing globals from functions called the runtime lookup method. To use this method, all new procedure files must contain the statement

```
#pragma rtGlobals = 1
```

All new programming should use the runtime lookup method and therefore all new procedure files should contain the `rtGlobals` pragma shown above. Igor automatically inserts the `rtGlobals=1` pragma when you create new procedure window.

Note: All discussion in this chapter assumes that `rtGlobals=1` is in effect, except for the section **Legacy Code Issues** on page IV-72.

The version Pragma

The `version` pragma sets the version of the procedure file. It is optional and is of interest mostly if you are the developer of a package used by a widespread group of users.

For details on the version pragma, see **Procedure File Version Information** on page IV-120.

The IgorVersion Pragma

The IgorVersion pragma is also optional and of interest to developers of packages. It gives you a way to prevent procedures from running, or at least generating compilation errors that cannot be fixed, under versions of Igor Pro older than the specified version number.

For example, the statement:

```
#pragma IgorVersion = 4.0
```

requires Igor Pro 4.0 or later for the procedure file. This will be helpful if you share your code with others because you can ensure that your procedures will only run with versions of Igor Pro that fully support all of the new or updated features you may have used. This Igor version check was added with Igor Pro 4.0, and it will not work with previous versions.

The ModuleName Pragma

The ModuleName pragma gives you the ability to use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line. Using this pragma entails a two step process: define a name for the procedure file, and then use a special syntax to access objects in the named procedure file.

To define a module name for a procedure file use the format:

```
#pragma ModuleName= name
```

This statement associates the specified module name with the procedure file in which the statement appears.

You can then use objects from the named procedure file by preceding the object name with the name of the module and the # character. For example:

```
#pragma ModuleName= myGreatProcedure
```

```
Static Function foo(a)  
    variable a  
  
    return a+100  
End
```

Then on the command line you can execute:

```
Print myGreatProcedure#foo(3)
```

You should make sure the name is unlikely to clash with other names you or others might use. WaveMetrics will use names with a WM_ prefix, so you should avoid such names. The ModuleName pragma will not work with versions previous to Igor Pro 5.0.

The IndependentModule Pragma

The IndependentModule pragma is a way for you to designate groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

A file is designated as an independent module using

```
#pragma IndependentModule=imName
```

This is similar to `#pragma ModuleName=modName` (see **The ModuleName Pragma** on page IV-40) and, just as in the case of calling static functions in a procedure with `#pragma ModuleName`, calling nonstatic function in an IndependentModule from outside the module requires the use of `imName#functionName()` syntax.

Because all procedure files in a given independent module are compiled separately from all other files, function names never conflict with those outside the group and there is little or no need to use the static

designation on functions in an independent module. However, if need be, you can call static functions in the independent module from outside the group using a triple name syntax:

```
imName#modName#functionName()
```

Limitations of Independent Modules

Independent modules are not for every-day programming and are somewhat more difficult to create than normal modules because of the following limitations:

1. Macros and Procs are not supported.
2. Button and control dialogs do not list functions in an IndependentModule.
3. Functions in an independent module can not call outside that module unless they use Execute.
4. The IndependentModule pragma will not work with versions previous to Igor Pro 6.

By default, the debugger is disabled for independent modules. It can be enabled using:

```
SetIgorOption IndependentModuleDev=1
```

Also by default, independent module procedure windows that are read-only or write-protected are not shown or available via the Windows menu unless you use `SetIgorOption IndependentModuleDev=1`.

Procedures loaded from the Igor Procedures folder or those loaded via the #include mechanism are read-only (write-protected).

When `SetIgorOption IndependentModuleDev=1` the procedure window titles show all procedure windows, and those that belong to an independent module show the name in brackets:

This syntax is used in the **WinList** (see page V-661), **FunctionList** (see page V-180), **DisplayProcedure** (see page V-107), and **ProcedureText** (see page V-445) functions and operations.

Files loaded via #include are made part of a module by inserting a `#pragma IndependentModule` statement at the start of the file. If the same file is included several times, there will be several copies each with a different independent module name.

Although code in one independent module can not directly call routines in another independent module or in global (nonindependent module) procedures, it can use Execute to call such routines.

In the case of global functions, you must prepend `ProcGlobal#` to the function name:

```
Execute "ProcGlobal#foo()"
```

Calling nonstatic functions in other independent modules will need the independent module name prepended:

```
Execute "ThatOtherIndependentModule#bar()"
```

Calling static functions in other independent modules will need the independent module name and a required module name prepended:

```
Execute "ThatOtherIndependentModule#ThatModuleName#staticbar()"
```

Chapter IV-3 — User-Defined Functions

Development Tips

Development of an independent module may be easier if it is first done as for normal code. Add the module declaration

```
#pragma IndependentModule=moduleName
```

only after the code has been fully debugged and is working properly.

As a convenience, and to make #include files more useful, the names of control and hook functions are examined at runtime, and if running from an independent module, its name is inserted if needed. This means you can use something like

```
Button b0,proc=myFunc
```

and don't have to use

```
Button b0,proc=myImName#myFunc
```

Such independent module name insertion is only done when an operation is running in a function (or when compiling user-defined menu definitions, see **Independent Modules and User-Defined Menus** on page IV-43).

Independent module name insertion is not done if the operation is being executed on the command line or via Execute.

If you need to call a function in the current independent module using Execute, you can compose the name using the **GetIndependentModuleName** function (see page V-189). For example, without #pragma IndependentModule=imName the commands would be:

```
String cmd= "WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
Execute cmd
```

But with independent module the commands are:

```
#pragma IndependentModule=myIM

String cmd= "WS_UpdateWaveSelectorWidget(\"Panel0\", \"selectorWidgetName\")"
cmd= GetIndependentModulename() + "#" + cmd // prepend independent module name#
Execute cmd
```

You could change the command string to:

```
cmd = "myIM#" + cmd
```

but the use of GetIndependentModuleName can disable the #pragma IndependentModule and have the code still work.

GetIndependentModuleName is also useful for defining dependencies using functions in the current independent module. In order for dependencies to evaluate correctly (dependencies are evaluated in global procedure scope just as with the Execute parameter), the dependency must use GetIndependentModuleName to create a formula to pass to the **SetFormula** operation (see page V-495). For example, without #pragma IndependentModule=imName:

```
String formula= "foo(root:wave0)"
SetFormula root:aVariable $formula
```

But with independent module:

```
#pragma IndependentModule=myIM

String formula= GetIndependentModulename() + "#foo(root:wave0)"
SetFormula root:aVariable $formula
```

Another such situation is with the value parameter of a **PopupMenu** (see page V-432) when the menu content is generated by a user-defined string function in the independent module. For example without #pragma IndependentModule=imName:

```
Function/S myPopupMenuList()
    return "item 1;item2;"
```

```

End
...
PopupMenu pop0 value= #"myPopupMenuList()"// note the quotation marks

But with independent module:

#pragma IndependentModule=myIM

Function/S myPopupMenuList()
    return "item 1;item2;"
End
...
String cmd= GetIndependentModuleName()+"#myPopupMenuList()"
PopupMenu pop0 value= #cmd           // no enclosing quotation marks

```

Note that `#cmd` is **not** the same as `#"cmd"`. The `#command` form is a new syntax introduced with Igor Pro 6. When the PopupMenu is clicked, the string expression is evaluated before it is stored as the command for execution in global scope. (The older `#"commandString"` format stores *commandString* literally as the command to be executed in global scope whereas `GetIndependentModuleName` always returns "ProcGlobal" and not "myIM".)

Independent Modules and User-Defined Menus

Independent module procedures can contain user-defined menus. With a `#pragma IndependentModule` statement, Igor will inspect the execution text of the menu definition and possibly prepend the independent module name if needed (because execution text is executed in the global procedure scope):

```

#pragma IndependentModule=myIM

Menu "Macros"
    "Load Data File/1", Beep; LoadWave/G
    "Do Analysis/2", Func()
End

Function Func()
    ... analysis code here...
End

```

Without the `#pragma IndependentModule` statement, choosing the Do Analysis menu item would execute `Func` without any trouble because `Func` is in the global procedure scope.

With the `#pragma IndependentModule` statement, `Func` is hidden (like static functions) from the global procedure scope (for example, from the Command Line), and will fail without assistance.

Igor provides the assistance, which allows the procedure to work correctly with or without a `#pragma IndependentModule` statement, by prepending the independent module name and a `#` character as if the menu definition were:

```
"Do Analysis/2", myIM#Func()
```

This assistance is provided when the execution text starts with a name and a left parenthesis and when the name is a user-defined function in the procedure's independent module (the function can be in a different procedure file that is part of the same independent module).

When the execution text doesn't start with a user-defined function name, the text is unaltered (as for the Load Data File menu definition example).

Note: If a procedure with menu definitions is opened multiple times (for example, included into multiple independent modules, the menus are repeatedly defined. Judicious use of the `menus=0` option in the `#include` statements helps prevent this. See **Turning the Included File's Menus Off** on page IV-120.

Unknown Pragmas

Starting with Igor Pro version 3.04, Igor ignores pragmas that it does not know about. This allows newer versions of Igor to use new pragmas while older versions ignore them. The downside of this change is that, if you misspell a pragma keyword, Igor will not warn you about it.

Proc Pictures

Proc Pictures are binary PNG or JPEG images encoded as printable ASCII procedures in procedure files. They are intended for programmers who need images as part of the user interface for a procedure package. They can be used with the **DrawPICT** operation (see page V-116) and with the **Picture** keyword (see page V-425) in certain controls.

The syntax for defining and using a Proc Picture is illustrated in the following example:

```
// PNG: width= 56, height= 44
Picture myPictName
  ASCII85Begin
    M,6r;%14!\!!!!.8Ou6I!!!!Y!!!!M#Qau+!5G;q_uKc;&TgHDFAm*iFE_/6AH5;7DfQssEc39jTBQ
    =U!7FG,5u`*!m?g0PK.mR"U!k63rtBW) ]$T)Q*!=Sa1TCDV*V+1:Lh^NW!ful>;(.<VU1bs4L8&@Q_
    <4e("%^F50:Jg6);j!CQdUA[dh6] %[OkHSC,ht+Q7ZO#.6U,IgfSZ!R1g':oO_iLF.GQ@RF[/*G98D
    bJE.g?NCte(pX-($m^\_FhhfL`D9uO6Qi5c[r4849Fc7+*)*O[tY(6<rkm^)/KLlc]VdDEbF-n5&Am
    2^hbTu:U#8ies_W<LGkp_LEU1bs4L8&?fqRJ[h#sVSSz8OZBBY!QNJ
  ASCII85End
End

Function test()
  NewPanel
  DrawPict 0,0,1,1,ProcGlobal#myPictName
End
```

The ASCII text in the `myPictName` procedure between the `ASCII85Begin` and `ASCII85End` is similar to output from the Unix `btoa` command or, on Macintosh, StuffIt's binary to ASCII operation. (You must remove any extra header and trailer information if you use either of these utilities to create a Proc Picture.)

You can create Proc Pictures in Igor Pro from normal, global pictures using the Picture dialog (see **Pictures** on page III-405). Select a picture in the dialog and click the Copy Proc Picture button to place the text on the Clipboard and then paste it in your procedure file. If the existing picture is not a JPEG or PNG, it is converted to PNG.

Proc Pictures can be either global or local in scope. Global pictures can be used in all experiment procedure files; local pictures can be used only within the procedure file where they are defined. Proc Pictures are global by default and the picture name must be unique for all procedure files in an experiment. Proc Pictures can be made local in scope by declaring them Static (see **Static** on page V-533).

When accessing a Proc Picture from `DrawPict`, the picture name must be preceded by either the `ProcGlobal` keyword or the procedure module name, and the two names joined together with `#`. This naming convention is necessary to avoid potential conflicts with any existing experiment global pictures defined via the Pictures dialog.

For a global Proc Picture, you must use the `ProcGlobal` keyword as the prefix:

```
ProcGlobal#gProcPictName
```

For a static Proc Picture, you must use the module name defined in the procedure file by the `#pragma ModuleName = modName` statement (see **ModuleName** on page V-375) as the prefix:

```
modName#ProcPictName
```

How Parameters Work

There are two ways of passing parameters from a routine to a subroutine: **pass-by-value** and **pass-by-reference**. "Pass-by-value" means that the routine passes the *value* of an expression to the subroutine. "Pass-by-reference" means that the routine passes *access to a variable* to the subroutine. The important difference is that, in pass-by-reference, the subroutine can change the original variable in the calling routine.

The C and Pascal languages allow programmers to use either of these techniques, at their option while FORTRAN uses pass-by-reference only. Like C, Igor also allows either method for numeric and string variables.

Example of Pass-By-Value

```
Function Routine()  
    Variable v = 4321  
    String s = "Hello"  
  
    Subroutine(v, s)  
End  
  
Function Subroutine(v, s)  
    Variable v  
    String s  
  
    Print v, s  
  
    // These lines have NO EFFECT on the calling routine.  
    v = 1234  
    s = "Goodbye"  
End
```

Note that *v* and *s* are *local variables* in Routine. In Subroutine, they are *parameters* which act very much like local variables. The names “*v*” and “*s*” are local to the respective functions. The *v* in Subroutine is not the same variable as the *v* in Routine although it initially has the same value.

The last two lines of Subroutine set the value of the local variables *v* and *s*. They have no effect on the value of the variables *v* and *s* in the calling Routine. What is passed to Subroutine is the numeric value 4321 and the string value “Hello”.

Pass-By-Reference

You can specify that a parameter to a function is to be passed by reference rather than by value. In this way, the function called can change the value of the parameter and update it in the calling function. This is much like using pointers to arguments in C. This technique is needed and appropriate only when you need to return more than one value from a function.

The variable or string being passed must be a local variable and can not be a global variable. To designate a variable or string parameter for pass-by-reference, simply prepend an ampersand symbol (&) before the name in the parameter declaration:

```
Function Subroutine(num1,num2,str1)  
    Variable &num1, num2  
    String &str1  
  
    num1= 12+num2  
    str1= "The number is"  
End
```

and then call the function with the name of a local variable in the reference slot:

```
Function Routine()  
    Variable num= 1000  
    String str= "hello"  
    Subroutine(num,2,str)  
    print str, num  
End
```

When executed, Routine prints “The number is 14” rather than “hello 1000”, which would be the case if pass-by-reference were not used.

A pass-by-reference parameter can be passed to another function that expects a reference:

```
Function SubSubroutine(b)  
    Variable &b
```

Chapter IV-3 — User-Defined Functions

```
    b= 123
End

Function Subroutine(a)
    Variable &a
    SubSubroutine(a)
End

Function Routine()
    Variable num
    Subroutine(num)
    print num
End
```

Note: Functions with pass-by-reference parameters can only be called from other functions — not from the command line.

How Waves Are Passed

Here is an example of a function “passing a wave” to a subroutine.

```
Function Routine()
    Make/O wave0 = x
    Subroutine(wave0)
End

Function Subroutine(w)
    WAVE w

    w = 1234    // This line DOES AFFECT the wave referred to by w.
End
```

We are really not passing a wave to Subroutine, but rather we are passing a reference to a wave. The parameter *w* is the wave reference.

Waves are global objects that exist independent of functions. The subroutine can use the wave reference to modify the contents of the wave. Using the terminology of “pass-by-value” and “pass-by-reference”, the wave reference is passed by value, but this has the effect of “passing the wave” by reference.

Using Optional Parameters

Following is an example of a function with two optional input parameters:

```
Function opParamTest(a,b, [c,d])
    Variable a,b,c,d    // c and d are optional parameters

    // Determine if the optional parameters were supplied
    if( ParamIsDefault(c) && ParamIsDefault(d) )
        Print "Missing optional parameters c and d."
    endif

    Print a,b,c,d
End
```

Executing on the Command Line with none of the optional inputs:

```
•opParamTest(8,6)
    Missing optional parameters c and d.
    8  6  0  0
```

Executing with an optional parameter as an input:

```
•opParamTest(8,6, c=66)
    8  6  66  0
```

Note that the optional parameter is explicitly defined in the function call using the *ParamName=Value* syntax. All optional parameters must come after any required function parameters.

Local Versus Global Variables

Numeric and string variables can be **local** or **global**. “Local” means that the variable can be accessed only from within the procedure in which it was created. “Global” means that the variable can be accessed from the command line or from within any procedure. The following table shows the characteristics of local and global variables:

Local Variables	Global Variables
Are part of a procedure.	Are part of an Igor experiment.
Created using Variable or String within a procedure.	Created using Variable or String or Variable/G or String/G from the command line or within a procedure.
Used to store temporary results while the procedure is executing.	Used to store values that are saved from one procedure invocation to the next or to store data that is accessed by many procedures.
Cease to exist when the procedure ends.	Exist until you use KillVariables, KillStrings, or KillDataFolder.
Can be accessed only from within the procedure in which they were created.	Can be accessed from the command line or from within any procedure.

Local variables are private to the function in which they are declared and vanish when the function exits. Global variables are public and persistent — they exist until you explicitly delete them.

If you write a function whose main purpose is to display a dialog to solicit input from the user, you may want to store the user’s choices in global variables and use them to initialize the dialog the next time the user invokes it. This is an example of saving values from one invocation of a function to the next.

If you write a set of functions that loads, displays and analyzes experimentally acquired data, you may want to use global variables to store values that describe the conditions under which the data was acquired and to store the results from the analyses. These are examples of data accessed by many procedures.

Local Variables Used by Igor Operations

When invoked from a function, a number of Igor’s operations return results via local variables. For example, the WaveStats operation creates a number of local variables with names such as V_avg, V_sigma, etc. The following function illustrates this point.

```
Function PrintWaveAverage(w)
    WAVE w

    WaveStats/Q w
    Print V_avg
End
```

When the Igor compiler compiles the WaveStats operation, it creates various local variables, V_avg among them. When the WaveStats operation runs, it stores results in these local variables.

In addition to creating local variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific local variables to provide optional behavior. For example:

```
Function ExpFitWithMaxIterations(w, maxIterations)
    WAVE w
    Variable maxIterations

    Variable V_FitMaxIters = maxIterations

    CurveFit exp w
End
```

The CurveFit operation looks for a local variable named V_FitMaxIters, which sets the maximum number of iterations before the operation gives up.

The documentation for each operation lists the special variables that it creates or looks for.

Converting a String into a Reference Using \$

The \$ operator converts a string expression into an object reference. The object is usually a wave but can also be a global numeric or global string variable. This is a common and important technique.

We often use a string to pass the name of a wave to a procedure or to algorithmically generate the name of a wave. Then we use the \$ operator to convert the string into a wave reference so that we can operate on the wave.

The following trivial example shows why we need to use the \$ operator:

```
Function DisplayXY(xWaveName, yWaveName)
    String xWaveName, yWaveName

    Display $yWaveName vs $xWaveName
End
```

Here we use \$ to convert the string parameters into wave reference. The function will display the wave whose name is stored in the yWaveName string versus the wave whose name is stored in the xWaveName string.

If we omitted the \$ operators, we would have

```
Display yWaveName vs xWaveName
```

This would result in an error because the Display operation would look for a wave named yWaveName and would not find it.

As shown in the following example, \$ can create references to global numeric and string variables as well as to waves.

```
Function Test(vStr, sStr, wStr)
    String vStr, sStr, wStr

    NVAR v = $vStr          // v is local name for global numeric var
    v += 1
    SVAR s = $sStr          // s is local name for global string var
    s += "Hello"
    WAVE w = $wStr          // w is local name for global wave
    w += 1
End
```

```
Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
Test("gVar", "gStr", "gWave")
```

The NVAR, SVAR and WAVE references are necessary in functions so that the compiler can identify the kind of object. This is explained under **Accessing Global Variables and Waves** on page IV-49.

Compile Time Versus Runtime

Because Igor user-defined functions are compiled, you need to be aware of the difference between “compile time” and “runtime”.

Compile time is when Igor analyzes the text of all functions and produces low-level instructions that can be executed quickly later. This happens when you modify a procedure window and then:

- Choose Compile from the Macros menu.
- Click the Compile button at the bottom of a procedure window.
- Activate a nonprocedure window.

Runtime is when Igor actually executes a function’s low-level instructions. This happens when:

- You invoke the function from the command line.

- The function is invoked from another procedure.
- Igor updates a dependency which calls the function.
- You use a button or other control that calls the function.

Conditions that exist at compile time are different from those at runtime. For example, a function can reference a global variable. The global does not need to exist at compile time, but it does need to exist at runtime. This issue is discussed in detail in the following sections.

Here is another example of the distinction between compile time and runtime:

```
Function Example(w)
    WAVE w

    w= sin(x)
    FFT w
    w= r2polar(w)
End
```

The declaration “WAVE w” specifies that w is expected to be a real wave. This is correct until the FFT executes and thus the first wave assignment produces the correct result. After the FFT is executed at runtime, however, the wave becomes complex. The Igor compiler does not know this and so it will compile the second wave assignment on the assumption that w is real. A compile-time error will be generated complaining that r2polar is not available for this number type — i.e., real. To provide Igor with the information that the wave is complex after the FFT you need to rewrite the function like this:

```
Function Example(w)
    WAVE w

    w= sin(x)
    FFT w
    WAVE/C wc= w
    wc= r2polar(wc)
End
```

A statement like “WAVE/C wc= w” has the compile-time behavior of creating a symbol, wc, and specifying that it refers to a complex wave. It has the runtime behavior of making wc refer to a specific wave. The runtime behavior can not occur at compile time because the wave may not exist at compile time.

Accessing Global Variables and Waves

Global numeric variables, global string variables and waves can be referenced from any function. A function can refer to a global that does not exist at compile-time. For the Igor compiler to know what type of global you are trying to reference, you need to declare references to globals.

Consider the following function:

```
Function BadExample()
    gStr1 = "The answer is:"
    gNum1 = 1.234
    Print gStr1, gNum1
End
```

The compiler can not compile this because it doesn’t know what gStr1 and gNum1 are. We need to specify that they are a global string variable and a global numeric variable, respectively:

```
Function GoodExample1()
    SVAR gStr1 = root:gStr1
    NVAR gNum1 = root:gNum1
    gStr1 = "The answer is:"
    gNum1 = 1.234
    Print gStr1, gNum1
End
```

Chapter IV-3 — User-Defined Functions

The SVAR statement specifies two important things for the compiler: first, that gStr1 is a global string variable; second, that gStr1 refers to a global string variable named gStr1 in the root data folder. Similarly, the NVAR statement identifies gNum1. With this knowledge, the compiler can compile the function.

The technique illustrated here is called “runtime lookup of globals” because the compiler compiles code that associates the symbols gStr1 and gNum1 with specific global variables at runtime.

Runtime Lookup of Globals

The syntax for runtime lookup of globals is:

```
NVAR <local name1>[= <path to var1>][, <loc name2>[= <path to var2>]]...
SVAR <local name1>[= <path to str1>][, <loc name2>[= <path to str2>]]...
WAVE <local name1>[= <path to wave1>][, <loc name2>[= <path to wave2>]]...
```

NVAR and SVAR create a reference to a global numeric or string variable and WAVE creates a reference to a wave. At compile time, these statements identify the referenced objects. At runtime, the connection is made between the local name and the actual object. Consequently, the object must exist when these statements are executed.

<local name> is the name by which the global variable, string or wave is to be known within the user function. It does not need to be the same as the name of the global variable. The example function could be rewritten as follows:

```
Function GoodExample2()
    SVAR str1 = root:gStr1      // str1 is the local name.
    NVAR num1 = root:gNum1     // num1 is the local name.
    str1 = "The answer is:"
    num1 = 1.234
    Print str1, num1
End
```

If you use a local name that is the same as the global name, and if you want to refer to a global in the current data folder, you can omit the <path to ...> part of the declaration:

```
Function GoodExample3()
    SVAR gStr1                // Refers to gStr1 in current data folder.
    NVAR gNum1                // Refers to gNum1 in current data folder.
    gStr1 = "The answer is:"
    gNum1 = 1.234
    Print gStr1, gNum1
End
```

GoodExample3 accesses globals in the current data folder while GoodExample2 accesses globals in a specific data folder.

If you use <path to ...>, it may be a simple name (gStr1) or it may include a full or partial path to the name.

The following are valid examples, referencing a global numeric variable named gAvg:

```
NVAR gAvg= gAvg
NVAR avg= gAvg
NVAR gAvg
NVAR avg= root:Packages:MyPackage:gAvg
NVAR avg= :SubDataFolder:gAvg
NVAR avg= $"gAvg"
NVAR avg= $("g"+ "Avg")
NVAR avg= ::$"gAvg"
```

As illustrated above, the local name can be the same as the name of the global object and the lookup expression can be either a literal name or can be computed at runtime using \$<string expression>.

In some cases, it may be convenient to create global variables in a temporary data folder as a way of passing results back to the calling routine. For example:

```
Function MyWaveStats(inputWave)
    WAVE inputWave

    NewDataFolder/O/S tmpMyWaveStatsDF

    WaveStats/Q inputWave

    Variable/G gNumPoints = V_npnts
    Variable/G gAvg = V_avg
    Variable/G gSdev = V_sdev
End

Function Test()
    Make/O testwave= gnoise(1)

    MyWaveStats(testwave)          // Create temp output data folder.

    NVAR gNumPoints,gAvg,gSdev // Create references to globals.

    Printf "Points: %g; Avg: %g; SDev: %g\r", gNumPoints,gAvg,gSdev

    KillDataFolder :              // Kill temp output data folder.
End
```

Note that the NVAR statement must appear after the MyWaveStats call because NVAR associates the local names with existing global variables at runtime.

Runtime Lookup Failure

At runtime, it is possible that a NVAR, SVAR or WAVE statement may fail. For example, NVAR `v1= var1` will fail if `var1` does not exist in the current data folder when the statement is executed. You can use the NVAR_Exists, SVAR_Exists, and WaveExists functions to test if a given global reference is valid.

One cause for failure is putting a WAVE statement in the wrong place. For example:

```
Function BadExample()
    WAVE w = resultWave
    <Call a function that creates a wave named resultWave>
    Display w
End
```

This function will compile successfully but will fail at runtime. The reason is that the “WAVE `w = resultWave`” statement has the runtime behavior of associating the local name `w` with a particular wave. But that wave does not exist until the following statement is executed. The function should be rewritten as:

```
Function GoodExample()
    <Call a function that creates a wave named resultWave>
    WAVE w = resultWave
    Display w
End
```

Runtime Lookup Failure and the Debugger

You can break whenever a runtime lookup fails using the symbolic debugger (described in Chapter IV-8, **Debugging**). It is a good idea to do this, because it lets you know about runtime lookup failures at the moment they occur.

Sometimes you may create a WAVE, NVAR or SVAR reference knowing that the referenced global may not exist at runtime. Here is a trivial example:

```
Function Test()
    WAVE w = testWave
    if (WaveExists(testWave))
        Printf "testWave had %d points.\r", numpnts(testWave)
    endif
End
```

Chapter IV-3 — User-Defined Functions

If you enable the debugger's WAVE checking and if you execute the function when testWave does not exist, the debugger will break and flag that the WAVE reference failed. But you wrote the function to handle this situation, so the debugger break is not helpful in this case.

The solution is to rewrite the function using WAVE/Z instead of just WAVE. The /Z flag specifies that you know that the runtime lookup may fail and that you don't want to break if it does. You can use NVAR/Z and SVAR/Z in a similar fashion.

Accessing Complex Global Variables and Waves

You must specify if a global numeric variable or a wave is complex using the /C flag:

```
NVAR/C gc1= gc1
WAVE/C gcw1= gcw1
```

Accessing Text Waves

Text waves must be accessed using the /T flag:

```
WAVE/T tw= MyTextWave
```

Runtime Lookup Example

In this example, a function named Routine calls another function named Subroutine and needs to access a number of result values created by Subroutine. To make it easy to clean up the temporary result globals, Subroutine creates them in a new data folder. Routine uses the results created by Subroutine and then deletes the temporary data folder.

```
Function Subroutine(w)
    WAVE w

    NewDataFolder/O/S SubroutineResults    // Results go here

    WaveStats/Q w                        // WaveStats creates local variables
    Variable/G gAvg= V_avg               // Return the V_avg result in global gAvg
    Variable/G gMin= V_min
    String/G gWName= NameOfWave(w)

    SetDataFolder ::                     // Back to original data folder
End

Function Routine()
    Make aWave= {1,2,3,4}
    Subroutine(aWave)
    NVAR theAvg= :SubroutineResults:gAvg    // theAvg is local name
    NVAR theMin= :SubroutineResults:gMin
    SVAR theName= :SubroutineResults:gWName
    Print theAvg,theMin,theName
    KillDataFolder SubroutineResults    // We are done with results
End
```

Note that the NVAR statement must appear *after* the procedure (Subroutine in this case) that creates the global variable. This is because NVAR has both a compile-time and a runtime behavior. At compile time, it creates a name that Igor can compile (theAvg in this case). At runtime, it actually looks up and creates a link to the global (variable gAvg stored in data folder SubroutineResults in this case).

Often a Function will need to access quite a large number of global variables stored in a data folder. In such cases, you can write more compact code using the ability of NVAR, SVAR or WAVE to access multiple objects in the current data folder as illustrated here:

```
Function Routine2()
    Make/O aWave= {1,2,3,4}
    Subroutine(aWave)
```

```

String dfSav=GetDataFolder(1)
SetDataFolder :SubroutineResults
NVAR gAvg,gMin           // Access two variables via one NVAR
SVAR gWName
SetDataFolder dfSav

Print gAvg,gMin,gWName
KillDataFolder SubroutineResults    // We are done with results
End

```

Automatic Creation of NVAR and SVAR References

The Igor compiler sometimes automatically creates NVAR and SVAR references. For example:

```

Function Example1()
    Variable/G gVar1
    gVar1= 1

    String/G gStr1
    gStr1= "hello"
End

```

In this example we did not use NVAR or SVAR references and yet we were still able to compile assignment statements referring to global variables which will not exist until runtime. This is a feature of `Variable/G` and `String/G` that automatically create local references for simple object names.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. `Variable/G` and `String/G` do not create references if you use `$<name>`, a partial data folder path or a full data folder path to specify the object.

Automatic Creation of WAVE References

The Igor compiler sometimes automatically creates WAVE references. For example:

```

Function Example1()
    Make wave1
    wave1= x^2
End

```

In this example we did not use a WAVE reference and yet we were still able to compile an assignment statement referring to a wave which will not exist until runtime. This is a feature of the **Make** operation (see page V-325) which automatically creates local references for simple object names. The **Duplicate** operation (see page V-120) also creates local wave references.

Simple object names are names which are known at compile time for objects which will be created in the current data folder at runtime. **Make** and **Duplicate** do not create references if you use `$<name>`, a partial data folder path or a full data folder path to specify the object.

In the case of **Make** and **Duplicate** with simple object names, the type of the automatically created wave reference (real, complex or text) is determined by flags. `Make/C` and `Duplicate/C` create complex wave references. `Make/T` and `Duplicate/T` create text wave references. `Make` and `Duplicate` without type flags create real wave references. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Other operations also automatically create wave references for output waves (often called “destination” waves). For example, if you write:

```
DWT srcWave, destWave
```

it is as if you wrote:

```
DWT srcWave, destWave
WAVE destWave
```

After the discrete wavelet transform executes, you can reference `destWave` without an explicit wave reference.

Chapter IV-3 — User-Defined Functions

The FFT/DEST=<simple name> operation, by default, creates a complex wave reference for the destination wave. Thus:

```
FFT /DEST=output input
```

acts as if you wrote:

```
FFT /DEST=output input
Wave/C output
```

However, if a real wave reference for the same name already exists, FFT/DEST will not create a new wave reference. For example:

```
Wave output           // Real wave reference
FFT /DEST=output input // FFT does not create wave reference because
                        // it already exists.
```

Depending on various flags, after the FFT executes the actual destination wave may be real or complex. In the example above, it would be complex. If you need to use the destination wave later in the function in a wave assignment statement, you would need to create a complex wave reference for it, like this:

```
Wave output           // Real wave reference
FFT /DEST=output input
Wave/C out=output
out += cmplx(1,1)
```

Note that you can not use:

```
Wave/C output
```

for the last Wave declaration because it would conflict with the preceding one. You have to use a different name, “out” in this case.

The IFFT and WignerTransform operations are like the FFT operation except that, by default, they create real wave references.

WAVE Reference Types

When WAVE references are created at compile time, they are created with a specific numeric type or are defined as text. The compiler then uses this type when creating expressions based on the WAVE reference or when trying to match two instances of the same name. For example:

```
Make rWave
```

```
Make/C cWave
```

```
Make/T tWave
```

creates single precision real, single precision complex, and text WAVE reference variables. These types then define what kind of right-hand side expression to compile:

```
rWave= expression      // will be real
cWave= expression      // will be complex
tWave= expression      // will be text
```

At the present time, these are the only three types of expressions that the compiler creates and numeric expressions are always evaluated in double precision. However, in the future, the compiler might be extended to create integer or single precision code. As a result of these considerations, the compiler is sometimes quite picky about the exact congruence between two declarations of WAVE reference variables of the same name (which create just a single instance). For example:

```
WAVE aWave
if( !WaveExists(aWave) )
    Make/D aWave
endif
```

will give a compile error complaining about inconsistent type for a WAVE reference. This is because the default type for the WAVE reference is single precision real. In this case, you will need to use the /D flag like so:

```
WAVE/D aWave
```

WAVE Reference Type Flags

The **WAVE** reference (see page V-644) along with certain operations such as Duplicate can accept the following flags identifying the type of WAVE reference:

/B	8-bit signed integer destination waves, unsigned with /U.
/C	complex destination waves.
/D	double precision destination waves.
/I	32-bit signed integer destination waves, unsigned with /U.
/S	single precision destination waves.
/T	text destination waves.
/U	unsigned destination waves.
/W	16-bit signed integer destination waves, unsigned with /U.

These are the same flags used by the **Make** operation (see page V-325) except in this case they do not affect the actual wave and are used only specify what kind of wave is expected at runtime. This information is used if, later in the function, you create a wave assignment statement using a duplicated wave as the destination:

```
Function DupIt(wv)
    WAVE/C wv                // complex wave

    Duplicate/O/C wv,dupWv    // dupWv is complex
    dupWv[0]=cplx(5.0,1.0)    // no error, because dupWv known complex
    ...
End
```

If Duplicate did not have the /C flag, you would get a “function not available for this number type” message when compiling the assignment of dupWv to the result of the cplx function.

Problems with Automatic Creation of WAVE References

In some cases, the wave reference automatically created by an operation might be of the wrong type. For example, the FFT operation (see page V-139) automatically creates a complex wave reference for the destination wave, so if you write:

```
FFT/DEST=destWave srcWave
```

it is as if you wrote:

```
FFT/DEST=destWave srcWave
WAVE/C destWave
```

But the output of the FFT operation can sometimes be real, not complex. For example:

```
FFT/DEST=destWave/OUT=2 srcWave
```

The /OUT=2 flag creates a real destination wave. Thus the complex wave reference automatically created by the FFT operation is wrong and can not be used to subsequently access the destination wave. In this case, you must explicitly create a real wave reference, like this:

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE realDestWave = destWave
```

Note that you can not write:

Chapter IV-3 — User-Defined Functions

```
FFT/DEST=destWave/OUT=2 srcWave
WAVE destWave
```

because the FFT operation has already created a complex wave reference named `destWave`, so the compiler will generate an error. You must use a different name for the real wave reference.

The **IFFT** operation (see page V-221) has a similar problem but in reverse. IFFT automatically creates a real wave reference for the destination wave. In some cases, the actual destination wave will be complex and you will need to create an explicit wave reference in order to access it.

WAVE Reference Is Not Needed to Pass a Wave Parameter

You don't need to use a WAVE reference when passing a literal wave name as a parameter to an operation or function. For example:

```
Function Test()
    Display jack
    Display root:jack
    Variable tmp = mean(jack,0,100)
End
```

In these examples, Igor knows that the parameters of the Display operation and the first parameter of the mean function are waves and therefore does not need the additional information provided by the WAVE reference.

Creating Globals in a Specific Data Folder

There may be times when you want to create globals in a specific data folder rather than in the current data folder. This might be the case if you have written a package of procedures that creates its own data folder. Here is an example of this scenario.

```
Function Example2()
    if( !DataFolderExists("root:Packages:'My Package'") )
        Abort "Hey! 'My Package' doesn't exist"
        return -1
    endif

    Make root:Packages:'My Package':wave1
    Variable/G root:Packages:'My Package':gVar1
    String/G root:Packages:'My Package':gStr1

    WAVE wave1 = root:Packages:'My Package':wave1
    NVAR var1 = root:Packages:'My Package':gVar1
    SVAR str1 = root:Packages:'My Package':gStr1

    wave1= x^2
    var1= 1
    str1= "hello"
End
```

In this example, the parameters to Make, Variable/G and String/G are not simple (the objects are not in the current data folder). Therefore, Igor does not automatically create WAVE, NVAR and SVAR references so we need to explicitly create them. We could rewrite the function to use simple references as follows:

```
Function Example3()
    String dfSav= GetDataFolder(1)
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S root:Packages:'My Package'

    Make wave1
    Variable/G gVar1
    String/G gStr1

    wave1= x^2
    gVar1= 1
    gStr1= "hello"
```

```
SetDataFolder dfSav
End
```

In addition to eliminating the need for NVAR, SVAR and WAVE references, the second version creates the My Package data folder if it does not already exist.

Accessing Waves in Functions

To access a wave, we need to create, one way or another, a wave reference. The section **Accessing Global Variables and Waves** on page IV-49 explained how to access a wave using a WAVE reference. This section introduces several additional techniques. Other useful details may be found in **Returning Created Waves from User Functions** on page III-140.

We can create the wave reference by:

- Declaring a wave parameter
- Using \$<string expression>
- Using a literal wave name
- Using a wave reference function

Each of these techniques is illustrated in the following sections.

Each example shows a function and commands that call the function. The function itself illustrates how to deal with the wave within the function. The commands show how to pass enough information to the function so that it can access the wave. Other examples can be found in **Writing Functions that Process Waves** on page III-141.

Wave Reference Passed as Parameter

This is the simplest method. The function might be called from the command line or from another function.

```
Function Test(w)
    WAVE w                      // Wave reference passed as a parameter

    w += 1                      // Use in assignment statement
    Print mean(w,-INF,INF)      // Pass as function parameter
    WaveStats w                 // Pass as operation parameter
    AnotherFunction(w)          // Pass as user function parameter
End

Make/O/N=5 wave0 = p
Test(wave0)
Test($"wave0")
String wName = "wave0"; Test($wName)
```

In the first call to Test, the wave reference is a literal wave name. In the second call, we create the wave reference using \$<literal string>. In the third call, we create the wave reference using \$<string variable>. \$<literal string> and \$<string variable> are specific cases of the general case \$<string expression>.

If the function expected to receive a reference to a text wave, we would declare the parameter using:

```
WAVE/T w
```

If the function expected to be receive a reference to a complex wave, we would declare the parameter using:

```
WAVE/C w
```

If you need to return a large number of values to the calling routine, it is sometimes convenient to use a parameter wave as an output mechanism. The following example illustrates this technique:

```
Function MyWaveStats(inputWave, outputWave)
    WAVE inputWave
    WAVE outputWave

    WaveStats/Q inputWave
```

```
    outputWave[0] = V_npts
    outputWave[1] = V_avg
    outputWave[2] = V_sdev
End

Function Test()
    Make/O testwave= gnoise(1)

    Make/O/N=20 tempResultWave
    MyWaveStats(testwave, tempResultWave)
    Variable npts = tempResultWave[0]
    Variable avg = tempResultWave[1]
    Variable sdev = tempResultWave[2]
    KillWaves tempResultWave

    Printf "Points: %g; Avg: %g; SDev: %g\r", npts, avg, sdev
End
```

Wave Accessed Via String Passed as Parameter

This technique is of most use when the wave might not exist when the function is called. It is appropriate for functions that create waves.

```
Function Test(wName)
    String wName                // String containing a name for wave

    Make/O/N=5 $wName
    WAVE w = $wName             // Create a wave reference
    Print NameOfWave(w)
End

Test("wave0")
```

This example will create wave0 if it does not yet exist or overwrite it if it does exist. If we knew that the wave had to already exist, we could and should use the wave parameter technique shown in the preceding section. In this case, since the wave may not yet exist, we can not use a wave parameter.

Notice that we create a wave reference immediately after making the wave. Once we do this, we can use the wave reference in all of the ways shown in the preceding section. We can not create the wave reference before making the wave because a wave reference must refer to an existing wave.

The following command demonstrates that \$wName and the wave reference w can refer to a wave that is not in the current data folder.

```
NewDataFolder root:Folder1; Test("root:Folder1:wave0")
```

Wave Accessed Via String Calculated in Function

This technique is used when creating multiple waves in a function or when algorithmically selecting a wave or a set of waves to be processed.

```
Function Test(baseName, startIndex, endIndex)
    String baseName
    Variable startIndex, endIndex

    Variable index = startIndex
    do
        WAVE w = $(baseName + num2istr(index))
        WaveStats/Q w
        Printf "Wave: %s; average: %g\r", NameOfWave(w), V_avg
        index += 1
    while (index <= endIndex)
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Test("wave", 0, 2)
```

We need to use this method because we want the function to operate on any number of waves. If the function were to operate on a small, fixed number of waves, we could use the wave parameter method.

As in the preceding section, we create a wave reference using `$<string expression>`.

Wave Accessed Via Literal Wave Name

In data acquisition or analysis projects, you often need to write procedures that deal with runs of identically-structured data. Each run is stored in its own data folder and contains waves with the same names. In this kind of situation, you can write a set of functions that use literal wave names specific for your data structure.

```
Function CreateRatio()
    WAVE dataA, dataB
    Duplicate dataA, ratioAB
    WAVE ratioAB
    ratioAB = dataA / dataB
End

Make/O/N=5 dataA = 1 + p, dataB = 2 + p
CreateRatio()
```

The CreateRatio function assumes the structure and naming of the data. The function is hard-wired to this naming scheme and assumes that the current data folder contains the appropriate data.

Wave Accessed Via Wave Reference Function

A wave reference function is a built-in Igor function that returns a reference to a wave. Wave reference functions are typically used on the right-hand side of a WAVE statement. For example:

```
WAVE w = WaveRefIndexed("", i, 4)
```

A common use for a wave reference function is to get access to waves displayed in a graph, using the TraceNameToWaveRef function. Here is an example.

```
Function PrintAverageOfDisplayedWaves()
    String list, traceName

    list = TraceNameList("", ";", 1)    // List of traces in top graph
    Variable index = 0
    do
        traceName = StringFromList(index, list)    // Next trace name
        if (strlen(traceName) == 0)
            break    // No more traces
        endif
        WAVE w = TraceNameToWaveRef("", traceName) // Get wave ref
        WaveStats/Q w
        Printf "Wave: %s; average: %g\r", NameOfWave(w), V_avg
        index += 1
    while (1)    // loop till break above
End

Make/O/N=5 wave0=gnoise(1), wave1=gnoise(1), wave2=gnoise(1)
Display wave0, wave1, wave2
PrintAverageOfDisplayedWaves()
```

There are other wave reference functions (see **Wave Reference Functions** on page IV-143), but WaveRefIndexed and TraceNameToWaveRef are the most used.

Destination Wave Parameters

Many operations create waves. Examples are Make, Duplicate, and Differentiate. Such operations take “destination wave name” parameters. Their parameters are not wave parameters. For example, the following is incorrect:

```
Function Test()
    Wave wave0 = root:FolderA:wave0
```

Chapter IV-3 — User-Defined Functions

```
    Make wave0                                // WRONG
    wave0 = sin(x/8)
    Display wave0
End
```

This function attempts to pass a wave parameter to Make but Make does not take a wave parameter. A wave parameter must refer to an existing wave. Since Make creates waves, its parameters may refer to waves that do not yet exist and so the parameters must be destination wave names, not waves. Make will treat wave0 as the destination wave name and will make a wave in the current data folder, not in root:FolderA.

This function should be written like this:

```
Function Test()
    Make root:FolderA:wave0                    // CORRECT
    Wave wave0 = root:FolderA:wave0
    wave0 = sin(x/8)
    Display wave0
End
```

Unlike Make, Display does take a wave parameter. Like many operations, the parameters to Display must be existing waves. Parameters that represent existing waves are wave parameters whereas parameters that represent the names of waves to be created are destination wave name parameters.

Trace Name Parameters

The ModifyGraph operation takes trace name parameters. A trace name is not the same as a wave. An example may clarify this subtle point:

```
Function Test()
    Wave w = root:FolderA:wave0
    Display w
    ModifyGraph rgb(w) = (65535,0,0)           // WRONG
End
```

This is wrong because ModifyGraph is looking for the name of a trace in a graph and w is not the name of a trace in a graph. The name of the trace in this case is wave0. The function should be written like this:

```
Function Test()
    Wave w = root:FolderA:wave0
    Display w
    ModifyGraph rgb(wave0) = (65535,0,0)       // CORRECT
End
```

In the next example, the wave is passed to the function as a parameter so the name of the trace is not so obvious:

```
Function Test(w)
    Wave w
    Display w
    ModifyGraph rgb(w) = (65535,0,0)           // WRONG
End
```

This is wrong for the same reason as the first example: w is not the name of the trace. The function should be written like this:

```
Function Test(w)
    Wave w
    Display w

    String name = NameOfWave(w)
    ModifyGraph rgb($name) = (65535,0,0)       // CORRECT
End
```

Structures in Functions

You can define structures in procedure files and use them in functions. Structures can be used only in user-defined functions as local variables and their behavior is defined almost entirely at compile time. Runtime or interactive definition and use of structures is not currently supported (for this purpose, use Data Folders (see Chapter II-8, **Data Folders**), the **StringByKey** function (see page V-602), or the **NumberByKey** function (see page V-404)).

Use of structures is an advanced technique. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

Defining Structures

Structures are defined in a procedure file with the following syntax:

```
Structure structureName
    memType memName [arraySize] [, memName [arraySize]]
    ...
EndStructure
```

Structure member types (*memType*) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

Igor Member Type	C Equivalent	Byte Size
char	signed char	1
uchar	unsigned char	1
int16	short int	2
uint16	unsigned short int	2
int32	long int	4
uint32	unsigned long int	4
float	float	4
double	double	8

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).

The optional *arraySize* must be specified using an expression involving literal numbers or locally-defined constants enclosed in brackets. The value must be between 1 and 100. The upper limit is a consequence of how memory is allocated on the stack frame.

Structures are two-byte aligned. This means that if an odd number of bytes has been allocated and then a nonchar field is defined, an extra byte of padding will be inserted in front of the new field. This is mainly of concern only when reading and writing structures from and to disk files.

The Structure keyword can be preceded with the **Static** keyword (see page V-533) to make the definition apply only to the current procedure window. Without the Static designation, structures defined in one procedure window may be used in any other.

Using Structures

To use (“instantiate”) a structure in a function, you must allocate a STRUCT variable using:

```
STRUCT sName name
```

Chapter IV-3 — User-Defined Functions

where *sName* is the name (or “tag” if you’re a C programmer) of an existing structure and *name* is the local variable name (sometimes called the “instance name”). (See **STRUCT** on page V-606 for details.)

To access a member of a structure, specify the STRUCT variable name followed by a “.” and the member name:

```
STRUCT Point pt
pt.v= 100
```

When a member is defined as an array:

```
Structure mystruct
  Variable var1
  Variable var2[10]
...
EndStructure
```

you must specify [*index*] to use a given element in the array:

```
STRUCT mystruct ms
ms.var2[n]= 22
```

The names must be literal and can not use *\$str* notation. The *index* value can be calculated at runtime (it doesn’t have to be a literal number). If the field is itself a STRUCT, continue to append “.” and field names as needed. See the **Example** on page IV-62.

Note that you can **not** define an array of structures:

```
STRUCT Point pt[100]           // Not allowed
```

WAVE, NVAR, SVAR, and FUNCREF members can be initialized using the same syntax as used for the corresponding nonstructure variables. See **Runtime Lookup of Globals** on page IV-50 and **Function References** on page IV-67.

Structures may be passed to functions **only** by reference (as with Fortran), which allows them to be both input and output parameters (see **Pass-By-Reference** on page IV-45). The syntax is:

```
STRUCT sName &varName
```

In a user function you define the input parameter:

```
Function myFunc(s)
  STRUCT mystruct &s
...
End
```

Char and uchar arrays can be treated as zero-terminated strings by leaving off the brackets. Because the Igor compiler knows the size, the entire array can be used with no zero termination. Like normal string variables, concatenation using += is allowed but substrings assignment using [*p1*,*p2*]= *subStr* is not supported.

Structures, including substructures, may be copied using simple assignment from one structure to the other. The source and destination structures must be defined using the same structure name (tag).

The **Print** operation (see page V-437) can print individual elements of a structure or can print a summary of the entire STRUCT variable.

Example

Here is a (somewhat contrived) example using structures. Try executing `foo(2)`:

```
Constant kCaSize= 5

Structure substruct
  Variable v1
  Variable v2
EndStructure

Structure mystruct
  Variable var1
  Variable var2[10]
```

```

String s1
WAVE fred
NVAR globVar1
SVAR globStr1
FUNCREF myDefaultFunc afunc
STRUCT substruct ssl[3]
char ca[kCaSize+1]
EndStructure

Function foo(n)
    Variable n

    Make/O/N=20 fred
    Variable/G globVar1= 111
    String/G aGlobStr="a global string var"

    STRUCT mystruct ms
    ms.var1= 11
    ms.var2[n]= 22
    ms.s1= "string s1"
    WAVE ms.fred      // could have =name if want other than waves named fred
    NVAR ms.globVar1
    SVAR ms.globStr1= aGlobStr
    FUNCREF myDefaultFunc ms.afunc= anotherfunc
    ms.ssl[n].v1= ms.var1/2
    ms.ssl[0]= ms.ssl[n]
    ms.ca= "0123456789"
    bar(ms,n)
    print ms.var1,ms.var2[n],ms.s1,ms.globVar1,ms.globStr1,ms.ssl[n].v1
    print ms.ss 1[n].v2,ms.ca,ms.afunc()
    print "a whole wave",ms.fred
    print "the whole ms struct:",ms

    STRUCT substruct ss
    ss= ms.ssl[n]
    print "copy of substruct",ss
End

Function bar(s,n)
    STRUCT mystruct &s
    Variable n

    s.ssl[n].v2= 99
    s.fred= sin(x)
    Display s.fred
End

Function myDefaultFunc()
    return 1
End

Function anotherfunc()
    return 2
End

```

Note the use of WAVE, NVAR, SVAR and FUNCREF in the function foo. These keywords are required both in the structure definition and again in the function, when the structure members are initialized.

Built-In Structures

Igor includes a few special purpose, predefined structures for use with certain operations. Some of those structures use these predefined general purpose structures:

```

Structure Rect
    Int16 top,left, bottom,right
EndStructure

Structure Point
    Int16 v,h
EndStructure

```

Chapter IV-3 — User-Defined Functions

A number of operations use built-in structures that the Igor programmer can use. See the command reference information for details about these structures and their members.

Operation	Structure Name
Button	WMButtonAction
CheckBox	WMCheckboxAction
CustomControl	WMCustomAction
ListBox	WMListboxAction
ModifyFreeAxis	WMAxisHookStruct
PopupMenu	WMPopupAction
SetVariable	WMSetVariableAction
SetWindow	WMWinHookStruct
Slider	WMSliderAction
TabControl	WMTabControlAction

Applications of Structures

Structures are useful for reading and writing disk files. The **FBinRead** operation (see page V-137) and the **FBinWrite** operation (see page V-138) understand structure variables and will read or write the entire structure from or to a disk file. The individual fields of the structure will be byte-swapped if you use the /B flag.

Structures can be used in complex programming projects to reduce the dependency on global objects and to simplify passing data to and getting data from functions. For example, a base function might allocate a local structure variable and then pass that variable on to a large set of lower level routines. Because structure variables are passed by reference, data written into the structure by lower level routines is available to the higher level. Without structures, you would have to pass a large number of individual parameters or use global variables and data folders.

Using Structures with Windows and Controls

Predefined structures are available for “new-style” (new as of Igor Pro 5) action procedures for controls and hook functions for windows. See the documentation for each of the individual control listed in Chapter III-14, **Controls and Control Panels** and in Chapter V-1, **Igor Reference**, and the **SetWindow** operation (see page V-504).

Advanced programmers should also be aware of userdata that can be associated with windows using the **SetWindow** operation (see page V-504). Userdata is binary data that persists with individual windows; it is suitable for storing structures. Storing structures in a window’s userdata is very handy in eliminating the need for global variables and reduces the bookkeeping needed to synchronize those globals with the window’s life cycle. Userdata is also available for use with controls. See the **ControlInfo** operation (see page V-57), **GetWindow** operation (see page V-199), **GetUserData** operation (see page V-198), and **SetWindow** operation (see page V-504) operations.

Example

Here is an example illustrating Igor- and user-defined structures along with userdata in a control. Put the following in the procedure window of a new experiment and run the Panel0 macro. Then click on the buttons. Note that the buttons will remember their state even if the experiment is saved and reloaded. To fully understand this example, examine the definition of WMButtonAction in the **Button** operation (see page V-34).

```
#pragma rtGlobals=1          // Use modern global access method.

Structure mystruct
    Int32 nclicks
    double lastTime
EndStructure
```

```

Function ButtonProc(bStruct) : ButtonControl
    STRUCT WMButtonAction &bStruct

    if( bStruct.eventCode != 1 )
        return 0          // we only handle mouse down
    endif

    STRUCT mystruct s1
    if( strlen(bStruct.userdata) == 0 )
        print "first click"
    else
        StructGet/S s1,bStruct.userdata
        String ctime= Secs2Date(s1.lastTime, 1)+" "+Secs2Time(s1.lastTime,1)
        // Warning: Next command is wrapped to fit on the page.
        printf "button %s clicked %d time(s), last click =
%s\r",bStruct.ctrlName,s1.nclicks,ctime
    endif
    s1.nclicks += 1
    s1.lastTime= datetime
    StructPut/S s1,bStruct.userdata
    return 0
End

Window Panel0() : Panel
    PauseUpdate; Silent 1          // building window...

EndMacro

```

Limitations of Structures

Although structures can reduce the need for global variables, they do not eliminate them altogether. A structure variable, like all local variables in functions, disappears when its host function returns. In order to maintain state information, you will need to store and retrieve structure information using global variables. You can do this using a global variable for each field or, with certain restrictions, you can store entire structure variables in a single global using the **StructPut** operation (see page V-606) and the **StructGet** operation (see page V-606).

As of Igor Pro 5.03, a structure can be passed to an external operation or function. See the Igor XOP Toolkit manual for details.

Static Functions

You can create functions that are local to the procedure file in which they appear by inserting the keyword *Static* in front of *Function* (see **Static** on page V-533 for usage details). The main reason for using this technique is to minimize the possibility of your function names conflicting with other names. You can use common intuitive names instead of devising a special and sometimes ugly naming strategy.

Functions normally have global scope and are available in any part of an Igor experiment, but the static keyword limits the scope of the function to its procedure file and hides it from all other procedure files. Static functions can only be used in the file in which they are defined. They can not be called from the command line and they cannot be accessed from macros.

Because static functions cannot be executed from the command line, you will have write a public test function to test them.

You can break this rule and access a static function using a module name (see **The ModuleName Pragma** on page IV-40). This technique can test the function from the command line.

ThreadSafe Functions

ThreadSafe user functions provide support for computers with multiple processors and can be used for preemptive multitasking background tasks. A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads.

Note: With the exception of providing ThreadSafe functions to FuncFit, multitasking is for experts only. Writing a ThreadSafe function is not difficult but creating preemptive tasks is not for beginners.

You can create thread safe functions by inserting the keyword **ThreadSafe** in front of **Function**. For example:

```
ThreadSafe Function myadd(a,b)
    Variable a,b

    return a+b
End
```

Only a subset of functions and operations can be used in a ThreadSafe function. Generally, all numeric or utility functions can be used but those that access windows can not. To determine if a routine is ThreadSafe, use the Command Help tab of the Help Browser and choose ThreadSafe from the pop-up menu.

Although file operations are listed as ThreadSafe, they have certain limitations when running in a ThreadSafe function. If a file load hits a condition that normally would need user assistance, the load is aborted. No printing to history is done and there is no support for symbolic paths (use **PathInfo** and pass the path as a string input parameter).

ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. Non-ThreadSafe functions can call ThreadSafe functions.

When ThreadSafe functions execute in the main thread, they have normal access to data folders, waves, and variables. But when running in a preemptive thread, ThreadSafe functions use their own private data folders, waves, and variables. When a thread is started, waves can be passed to the function as input parameters. Such waves are then flagged as being in use by the thread, which prevents any changes to the size of the wave. When all threads under a given main thread are finished, the waves return to normal. You can pass data folders between the main thread and preemptive threads but such data folders are never shared.

See **ThreadSafe Functions and Multitasking** on page IV-214 for a discussion of programming with preemptive multitasking threads.

Function Overrides

In some rare cases, you may need to temporarily change an existing function. When that function is part of a package provided by someone else (or by WaveMetrics) it may be undesirable or difficult to edit the original function. By using the keyword “Override” in front of “Function” you can define a new function that will be used in place of another function of the same name that is defined in a *different and later* procedure file.

Although it is difficult to determine the order in which procedure files are compiled, the main procedure window is always first. Therefore, always define override functions in the main procedure file.

Although you can override static functions, you may run into a few difficulties. If there are multiple files with the same static function name, your override will affect all of them, and if the different functions have different parameters then you will get a link error.

Here is an example of the Override keyword. In this example, start with a new experiment and create a new procedure window. Insert the following in the new window (not the main procedure window).

```
Function foo()
    print "this is foo"
End
```

```
Function Test()
    foo()
End
```

Now, on the command line, execute Test(). You will see “this is foo” in the history.

Open the main procedure window and insert the following:

```
Override Function foo()
    print "this is an override version of foo"
End
```

Now execute Test() again. You will see the “this is an override version of foo” in the history.

Function References

Function references provide a way to pass a function to a function. This is a technique for advanced programmers. If you are just starting with Igor programming, you may want to skip this section and come back to it later.

To specify that an input parameter to a function is a function reference, use the following syntax:

```
Function Example(f)
    FUNCREF myprotofunc f
    ...
End
```

This specifies that the input parameter *f* is a function reference and that a function named *myprotofunc* specifies the kind of function that is legal to pass. The calling function passes the name of a function as the *f* parameter. The called function can use *f* just as it would use the prototype function.

If a valid function is not passed then the prototype function will be called instead. The prototype function can either be a default function or it can contain error handling code that makes it obvious that a proper function was not passed.

A similar syntax can be used to create function reference variables in the body of a function:

```
FUNCREF protoFunc f = funcName
FUNCREF protoFunc f = $"str"
FUNCREF protoFunc f = funcRef
```

As shown, the right hand side can take either a literal function name, a \$ expression that evaluates to a function name at runtime, or it can take another FUNCREF variable.

FUNCREF variables can refer to external functions as well as user functions. However, the prototype function must be a user function and it must not be static.

Although you can store a reference to a static function in a FUNCREF variable, you can not then use that variable with Igor operations that take a function as an input. FuncFit is an example of such an operation.

Following are some example functions and FUNCREFs that illustrate several concepts:

```
Function myprotofunc(a)
    Variable a

    print "in myprotofunc with a= ",a
End

Function fool(var1)
    Variable var1

    print "in fool with a= ",var1
End
```

Chapter IV-3 — User-Defined Functions

```
Function foo2(a)
    Variable a

    print "in foo2 with a= ",a
End

Function foo3(a)
    Variable a

    print "in foo3 with a= ",a
End

Function badfoo(a,b)
    Variable a,b

    print "in badfoo with a= ",a
End

Function bar(a,b,fin)
    Variable a,b
    FUNCREF myprotofunc fin

    if( a==1 )
        FUNCREF myprotofunc f= foo1
    elseif( a==2 )
        FUNCREF myprotofunc f= $"foo2"
    elseif( a==3 )
        FUNCREF myprotofunc f= fin
    endif
    f(b)
End
```

For the above functions, the following table shows the results for various invocations of the bar function executed on the command line:

Command	Result
bar(1,33,foo3)	in foo1 with a= 33
bar(2,44,foo3)	in foo2 with a= 44
bar(3,55,foo3)	in foo3 with a= 55
bar(4,55,foo3)	in myprotofunc with a= 55

Executing `bar(3,55,badfoo)` will generate a syntax error dialog that will highlight “badfoo” in the command. This error results because the format of the badfoo function does not match the format of the prototype function, myprotofunc.

Conditional Compilation

Compiler directives can be used to conditionally include or exclude blocks of code. This is especially useful when an XOP may or may not be available. It is also convenient for testing and debugging code. For example, to enable a block of procedure code depending on the presence or absence of an XOP use

```
#if Exists("nameOfAnXopRoutine")
    <procedure code using XOP routines>
#endif
```

The conditional compiler directives are modeled after the C/C++ language. Unlike other #keyword directives, these may be indented. For defining symbols, the directives are:

```
#define symbol
#undef symbol
```

For conditional compilation, the directives are:

```
#ifdef symbol
#ifdef symbol
#if expression
#elif expression
#else
#endif
```

Expressions are ordinary Igor expressions, but cannot involve any user-defined objects. They evaluate to TRUE if the absolute value is > 0.5 .

Conditionals must be either completely outside or completely inside function definitions; they cannot straddle a function definition. Conditionals cannot be used within Macros.

Nesting depth is limited to 16 levels. Trailing text other than a comment is illegal.

Note that #define is used purely for defining symbols (there is nothing like C's preprocessor) and the only use of a symbol is with #ifdef and #ifndef.

Unlike C, you cannot use #if defined(*symbol*).

Symbols exist only in the file where they are defined; the only exception is for symbols defined in the main procedure window, which are available to all other procedures except independent modules. In addition, you can define global symbols that are available in all procedure windows (including independent modules) using:

```
SetIgorOption poundDefine=symb
```

This adds one symbol to a global list. You can query the global list using

```
SetIgorOption poundDefine=symb?
```

This will set V_flag to TRUE if symb exists. To remove a symbol from the global list use

```
SetIgorOption poundUndefine=symb
```

For nonindependent module procedure windows, a symbol is defined if it exists in the global list *or* in the main procedure window's list *or* in the given procedure window.

For independent module procedure windows, a symbol is defined if it exists in the global list *or* in the given procedure window; it does not use the main procedure window list.

A symbol defined in a global list is not undefined by a #undef in a procedure window.

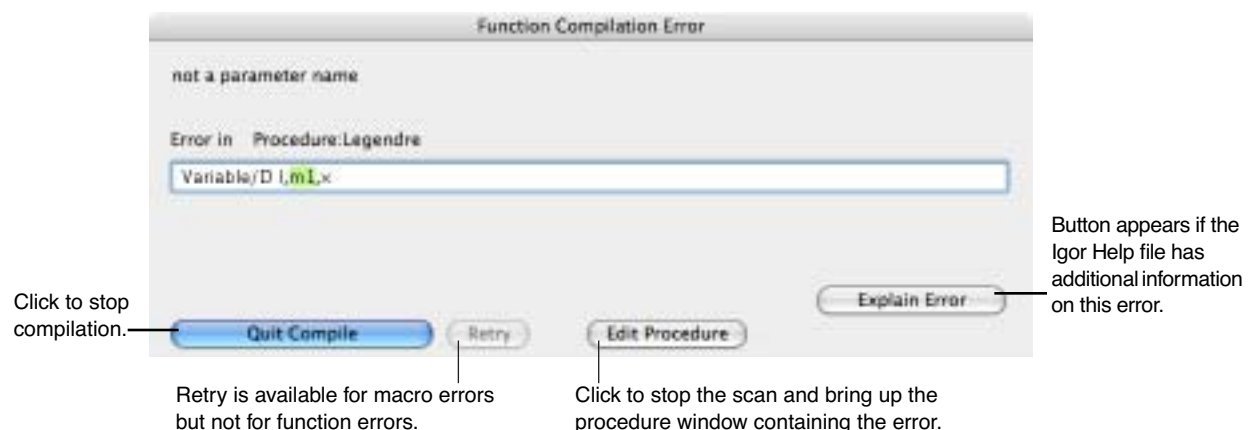

Conditional Compilation Examples

```
#define MYSYMBOL

#ifdef MYSYMBOL
Function foo()
    print "this is foo when MYSYMBOL is defined"
end
#else
Function foo()
    print "this is foo when MYSYMBOL is NOT defined"
end
#endif
```

Function Errors

During function compilation, Igor checks and reports syntactic errors and errors in parameter declarations. The normal course of action is to edit the offending function and try to compile again.

Runtime errors in functions are not reported on the spot. Instead, Igor saves information about the error and function execution continues. Igor presents an error dialog only after the last function ceases execution and Igor returns to the idle state. If multiple runtime errors occur, only the first is reported.

When a runtime error occurs, after function execution ends, Igor will present a dialog:

In this example, we tried to pass to the `AppendToGraph` function a reference to a wave that did not exist. To find the source of the error, you should use Igor's debugger and set it to break on error (see **Debugging on Error** on page IV-155 for details).

Sophisticated programmers may want to detect and deal with runtime errors on their own. The `GetRTErr` function (see page V-195) can be used to check if an error occurred, and optionally to clear the error so that Igor doesn't report it.

Coercion in Functions

The term "coercion" means the conversion of a value from one numeric precision or numeric type to another. Consider this example:

```
Function foo(awave)
    WAVE/C awave

    Variable/C var1

    var1= awave[2]*cplx(2,3)
    return real(var1)
End
```

The parameter declaration specifies that `awave` is complex. You can pass any kind of wave you like but it will be coerced into complex before use. For example, if you pass a real valued integer wave the value at point index 2 will be converted to double precision and zero will be used for the imaginary part.

Operations in Functions

You can call most operations from user-defined functions. To provide this capability, WaveMetrics had to create special code for each operation. Some operations weren't worth the trouble or could cause problems. If an operation can't be invoked from a function, an error message is displayed when the function is compiled. The operations that can't be called from a function are:

AppendToLayout	Layout	Modify	OpenProc
PrintGraphs	Quit	RemoveFromLayout	Stack
StackWindows	Tile	TileWindows	

If you need to invoke one of these operations from a user-defined function, use the Execute operation. See **The Execute Operation** on page IV-147.

Note that the ModifyGraph, ModifyTable and ModifyLayout operations *can* be called from a function.

Also, you can use the **NewLayout** operation (see page V-387) instead of Layout, the **AppendLayoutObject** operation (see page V-19) instead of AppendToLayout, and the **RemoveLayoutObjects** operation (see page V-457) instead of RemoveFromLayout.

External operations implemented by old XOPs also can not be called directly from user-defined functions. Again, the solution is to use the Execute operation.

Updates During Function Execution

An update is an action that Igor performs which consists of:

- Reexecuting formulas for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**);
- Redrawing graphs and tables which display waves that have changed;
- Redrawing page layouts containing graphs, tables, or annotations that have changed;
- Redrawing windows that have been uncovered.

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

When a function is executing, Igor does no automatic updates at all. However, you can force an update by calling the **DoUpdate** operation (see page V-110). Call DoUpdate if you don't want to wait for the next automatic update which will occur when function execution finishes.

Aborting Functions

There are two ways to prematurely stop procedure execution: a user abort or a programmed abort. Both stop execution of all procedures, no matter how deeply nested.

On Macintosh, you can abort procedure execution by pressing Command-period. On Windows, press Ctrl+Break or click the Abort button in the status bar. You may need to hold the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

A user abort does not directly return. Instead it sets a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs during procedure execution according to conditions set by the programmer.

The simplest programmed abort occurs when the **Abort** operation (see page V-12) is executed. Here is an example:

```
if( numCells > 10 )
    Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Other programmed aborts can be triggered using the **AbortOnRTE** and **AbortOnValue** flow control keywords. The try-catch-endtry flow control construct can be used for catching and testing for aborts. See **Flow Control for Aborts** on page IV-37 for more details.

Legacy Code Issues

This section discusses changes that have occurred in Igor programming over the years. If you are writing new code, you don't need to be concerned with these issues. If you are working with existing code, you may run into some of them.

If you are just starting to learn Igor programming, you have enough to think about already, so it is a good idea to skip this section. Once you are comfortable with the modern techniques described above, come back and learn about these antiquated techniques.

Old-Style Comments and Compatibility Mode

As of Igor Pro 4.0, the old comment character, a vertical bar (|), has been replaced and should no longer be used when writing new procedures. In Igor Pro 4.0 and later, the | character is used as the bitwise OR operator (see **Operators** on page IV-5).

In order to run old procedures which use | as the comment symbol, Igor supports a compatibility mode. This mode is a property of an experiment. When the current experiment is in compatibility mode, Igor interprets | as a comment symbol. Normally, when the current experiment is not in compatibility mode, Igor interprets | as bitwise OR.

You put the current experiment in compatibility mode by executing the following on the command line:

```
Silent 100
```

You take the current experiment out of compatibility mode by executing:

```
Silent 101
```

When you execute these commands, Igor automatically recompiles all procedure files in the current experiment using the new mode.

All experiments created pre-Igor 4 are automatically in compatibility mode until you update them and their procedures.

We strongly recommend that you update old experiments and procedures so that you don't need to use compatibility mode. Until you do so, your old experiments will not work with new procedure files that use | as bitwise OR. Here are the steps to update an experiment and its procedures:

1. In each old procedure file, replace each | symbol that is used to introduce a comment with //. Use Edit→Find and Edit→Find Same to find each occurrence of |. Do not do a mass replace because you may inadvertently change a | symbol used in the old bitwise OR operator (%|, which is still supported) or in a string.
2. On the command line, take the experiment out of compatibility mode by executing:

```
Silent 101
```

Igor will recompile procedures.
3. If there are any remaining obsolete uses of |, Igor will display a compile error dialog. Fix the error and recompile the procedures until you get no more errors.

If you create procedure files that are used by other people (either in your group or for public use) and you want to use the new logic operations, such as `|` (bitwise OR) or `||` (logical OR), which require compatibility mode to be off (`Silent 101`), then you can specify

```
#pragma rtGlobals=2
```

in place of the normal `rtGlobals=1`.

If your procedure file is included in an experiment running in compatibility mode (`Silent 100`) then an alert dialog will be presented that will allow the user to turn compatibility mode off. However, keep in mind that when the procedures are recompiled in the new mode, the user's other procedures will generate errors if they use the obsolete comment symbol.

Text After Flow Control

Prior to Igor Pro 4, Igor ignored any extraneous text after a flow control statement. Such text was an error, but Igor did not detect it.

Igor now checks for extra text after flow control statements. When found, a dialog is presented asking the user if such text should be considered an error or not. The answer lasts for the life of the Igor session.

Because previous versions of Igor ignored this extra text, it may be common for existing procedure files to have this problem. The text may in many cases simply be a typographic error such as an extra closing parenthesis:

```
if( a==1 ) )
```

In other cases, the programmer may have thought they were creating an `elseif` construct:

```
else if( a==2 )
```

even though the `"if(a==2)"` part was simply ignored. In some cases this may represent a bug in the programmer's code but most of the time it is asymptomatic.

Global Variables Used by Igor Operations

The section **Local Variables Used by Igor Operations** on page IV-47 explains that certain Igor operations create and set certain special local variables. That is true if the procedure file uses runtime lookup of globals (`rtGlobals=1` is in effect). In very old procedure files that use the obsolete direct reference method of accessing variables, the operations create and set global variables.

Also explained in **Local Variables Used by Igor Operations** on page IV-47 is the fact that some operations, such as `CurveFit`, look for certain special local variables which modify the behavior of the operations. For historic reasons, operations that look for special variables will look for global variables in the current data folder if the local variable is not found. This is true whether `rtGlobals=1` is in effect or not. This behavior is unfortunate and may be removed from Igor some day. New programming should use local variables for this purpose.

Direct Reference to Globals

The section **Accessing Global Variables and Waves** on page IV-49 explains how to access globals from a procedure file that uses runtime lookup of globals (`rtGlobals=1` is in effect). This section explains accessing globals in very old procedure files that use the obsolete direct reference method of accessing variables.

Prior to Igor Pro 3, Igor required that globals referenced from functions had to exist when the function was compiled. This was called the "direct reference" method of accessing globals. In Igor Pro 3, a new method, called the "runtime lookup" method, was added.

In a particular procedure file, the presence of the statement:

```
#pragma rtGlobals = 1
```

specifies that the file uses the runtime lookup method. If this statement is absent, or if the number used is 0 instead of the usual 1, the file uses the old direct reference method.

Chapter IV-3 — User-Defined Functions

All new programming should use the runtime lookup method and consequently all new procedure files should contain the `rtGlobals` pragma as shown above.

Future versions of Igor may remove the old method. Therefore Igor programmers should modify old procedure files to use it.

This section explains the old method. It is of interest only if you need to work with old files.

To compile a direct reference to a global, the global must exist at compile time. There are three ways to meet this requirement:

1. Create the global from the command line before compiling the procedures.
2. Declare the global in a function before the first use of the global.
3. Let Igor automatically create the global.

Method 1 works for waves, numeric variables and string variables. However, methods 2 and 3 work for numeric and string variables only, not for waves.

To use method 1, execute a `Make`, `Variable`, or `String` command from the command line before compiling procedures that refer to the global. This technique is not good for use with a separate utility procedure file because you would need to remember to create the globals each time you opened the file.

To use method 2, create a function at the top of the procedure file that declares all of the global variables used in the procedure file. For example:

```
#pragma rtGlobals=0          // Use old direct reference method

Function InitFilterProcGlobals()
    Variable/G gCutoffFrequency, gFilterType
    String/G gFilterErrorMessage

    gCutoffFrequency = 1.0
    gFilterType = 0
    gFilterErrorMessage = ""
End
```

This method works because, with `rtGlobals=0`, Igor creates the declared global variables and strings at compile time. When Igor compiles the `Variable/G` and `String/G` declarations, it creates the globals right then and there. Thus, the globals are guaranteed to exist when referenced later in this function or in any other function compiled after this function.

Although the globals are created at compile time, they will have default values (0 for numeric globals, "" for string globals) until the function actually runs. Compile-time declaration creates the globals but does not set their initial values.

Method number 3 occurs automatically when you compile, with `rtGlobals=0`, an operation (e.g., `WaveStats`) that returns results via global variables. Therefore the following will compile without error:

```
#pragma rtGlobals=0          // Use old direct reference method

Function WaveStdDev(w)
    WAVE w

    WaveStats/Q w
    return V_sdev
End
```

`V_sdev` is one of many global variable created by the `WaveStats` operation at compile time (if `rtGlobals=0` is in effect) but set to a value at runtime. Thus, when you compile `WaveStats` in a function, Igor creates these global variables.

By default (if a given procedure file contains no `rtGlobals` statement), `rtGlobals=0` is in effect. The “`#pragma rtGlobals=1`” statement affects only the procedure file in which it appears. If you enter it in your main pro-

cedure window, it will not affect any other included or explicitly opened procedure files. Use this to modernize one procedure file at a time.

The `rtGlobals` pragma can appear anywhere in the procedure file, even inside a function, and it can appear more than once. However, it should be sufficient in nearly all cases to have just one `rtGlobals` pragma near the beginning of the file.

Here are the steps for converting a procedure file to use the runtime lookup method for accessing globals:

1. Insert the `#pragma rtGlobals=1` statement, with no indentation, at or near the top of the procedure in the file.
2. Click the Compile button to compile the procedures.
3. If you use direct reference to access a global, Igor will display an error dialog indicating the line on which the error occurred. Add an `NVAR`, `SVAR` or `WAVE` reference.
4. If you encountered an error in step 3, return to step 2.

Overview

When we first created Igor, some time in the last millennium, it supported automation through macros. The idea of the macro was to allow users to collect commands into conveniently callable routines. Igor interpreted and executed each command in a macro as if it were entered in the command line.

WaveMetrics soon realized the need for a faster, more robust technology that would support full-blown programming. This led to the addition of user-defined functions. Because functions are compiled, they execute much more quickly. Also, compilation allows Igor to catch syntactic errors sooner. Functions have a richer set of flow control capabilities and support many other programming refinements. Over time, the role of macros has diminished in favor of functions.

Macros are still supported and there are still a few uses in which they are preferred. When you close a graph, table, page layout, or control panel, Igor offers to automatically create a window recreation macro which you can later run to resurrect the window. You can also ask Igor to automatically create a window style macro using the Window Control dialog. The vast majority of programming, however, should be done using functions.

The syntax and behavior of macros are similar to the syntax and behavior of functions, but the differences can be a source of confusion for someone first learning Igor programming. If you are just starting, you can safely defer reading the rest of this chapter until you need to know more about macros, if that time ever comes.

Comparing Macros and Functions

Like functions, macros are created by entering text in procedure windows. Each macro has a name, a parameter list, parameter declarations, and a body. Unlike functions, a macro has no return value.

Macros and functions use similar syntax. Here is an example of each. To follow along, open the Procedure window (Windows menu) and type in the macro and function definitions.

```
Macro MacSayHello(name)
    String name

    Print "Hello "+name
End

Function FuncSayHello(name)
    String name

    Print "Hello "+name
End
```

Now click in the Command window to bring it to the front. Use this to type commands into the command line and to compile the Procedure window.

If you execute the following on the command line

```
MacSayHello("John"); FuncSayHello("Sue")
```

you will see the following output printed in the history area:

```
Hello John
Hello Sue
```

This example may lead you to believe that macros and functions are nearly identical. In fact, there are a lot of differences. The most important differences are:

- Macros automatically appear in the Macros menu. Functions must be explicitly added to a menu, if desired, using a menu definition.
- Most errors in functions are detected when procedures are compiled. Most errors in macros are detected when the macro is executed.
- Functions run a lot faster than macros.
- Functions support wave parameters, for loops and switches while macros do not.

- Functions have a richer syntax.

If you look in the Macros menu, you will see MacSayHello but not FuncSayHello.

If you execute “FuncSayHello()” on the command line you will see an error dialog. This is because you must supply a parameter. You can execute, for example:

```
FuncSayHello( "Sam" )
```

On the other hand, if you run MacSayHello from the Macros menu or if you execute “MacSayHello()” on the command line, you will see a dialog that you use to enter the name before continuing:

This is called the “missing parameter dialog”. It is described under **The Missing Parameter Dialog** on page IV-83. Functions can display a similar dialog, called a simple input dialog, with a bit of additional programming.

Now try this: In both procedures, change “Print” to “xPrint”. Then click in the command window. You will see a dialog like this:

Click the Edit Procedure button and change “xPrint” back to “Print” in the function but not in the macro. Then click in the command window.

Notice that no error was reported once you fixed the error in the function. This is because only functions are compiled and thus only functions have their syntax completely checked at compile time. Macros are interpreted and most errors are found only when the line in the procedure window in which they occur is executed. To see this, run the macro by executing “MacSayHello("Sam")” on the command line.

You will then see this dialog:

Notice the box around the line containing the error. This box means you can edit its contents. If you change “xPrint” to “Print” in this dialog you will see that the Retry button becomes enabled. If you click this button, you can continue execution of the macro. When the macro finishes, take a look at the Procedure window.

You will notice that the correction you made in the dialog was put in the Procedure window and your “broken” macro is now fixed.

Macro Syntax

Here is the basic syntax for macros.

```
<Defining keyword> <Name> ( <Input parameter list> ) [:<Subtype>]
    <Input parameter declarations>

    <Local variable declarations>

    <Body code>
End
```

The Defining Keyword

<Defining keyword> is one of the following:

Defining Keyword	Creates Macro In
Window	Windows menu.
Macro	Macros menu.
Proc	—

The Window keyword is used by Igor when it automatically creates a window recreation macro. Except in rare cases, you will not write window recreation macros but instead will let Igor create them automatically.

The Procedure Name

The names of macros must follow the standard Igor naming conventions. Names can consist of up to 31 characters. The first character must be alphabetic while the remaining characters can include alphabetic and numeric characters and the underscore character. Names must not conflict with the names of other Igor objects, functions or operations. Names in Igor are case insensitive.

The Procedure Subtype

You can identify procedures designed for specific purposes by using a subtype. Here is an example:

```
Proc ButtonProc(ctrlName) : ButtonControl
    String ctrlName

    Beep
End
```

Here, “ : ButtonControl” identifies a macro intended to be called when a user-defined button control is clicked. Because of the subtype, this macro is added to the menu of procedures that appears in the Button Control dialog. When Igor automatically generates a procedure it generates the appropriate subtype. See **Procedure Subtypes** on page IV-149 for details.

The Parameter List and Parameter Declarations

The parameter list specifies the name for each input parameter. Macros have a limit of 10 parameters.

The parameter declaration must declare the type of each parameter using the keywords **Variable** or **String**. If a parameter is a complex number, it must be declared **Variable/C**.

Note: There should be no blank lines or other commands until after all the input parameters are defined. There should be one blank line after the parameter declarations, before the rest of the procedure. Igor will report errors if these conditions are not met.

Variable and string parameters in macros are always passed to a subroutine by value.

When macros are invoked with some or all of their input parameters missing, Igor displays a missing parameter dialog to allow the user to enter those parameters. In the past this has been a reason to use macros. However, as of Igor Pro 4, functions can present a similar dialog to fetch input from the user, as explained under **The Simple Input Dialog** on page IV-104.

Local Variable Declarations

The input parameter declarations are followed by the local variable declarations if the macro uses local variables. Local variables exist only during the execution of the macro. They can be numeric or string and are declared using the **Variable** or **String** keywords. They can optionally be initialized. Here is an example:

```
Macro Example(p1)
    Variable p1

    // Here are the local variables
    Variable v1, v2
    Variable v3=0
    Variable/C cv1=cplx(0,0)
    String s1="test", s2="test2"

    <Body code>
End
```

If you do not supply explicit initialization, Igor automatically initializes local numeric variables with the value zero and local string variables with the value "".

The name of a local variable is allowed to conflict with other names in Igor although they must be unique within the macro. Clearly if you create a local variable named "sin" then you will be unable to use Igor's built-in sin function within the macro.

You can declare a local variable in any part of a macro with one exception. If you place a variable declaration inside a loop in a macro then the declaration will be executed multiple times and Igor will generate an error since local variable names must be unique.

Body Code

The local variable declarations are followed by the body code. This table shows what can appear in body code of a macro.

What	Allowed in Macros?	Comments
Assignment statements	Yes	Includes wave, variable and string assignments.
Built-in operations	Yes	
External operations	Yes	
External functions	Yes	
Calls to user functions	Yes	
Calls to macros	Yes	
if-else-endif	Yes	
if-elseif-endif	No	
switch-case-endswitch	No	
strswitch-case-endswitch	No	
try-catch-endtry	No	
structures	No	
do-while	Yes	
for-endfor	No	
Comments	Yes	Comments start with //.

What	Allowed in Macros?	Comments
break	Yes	Used in loop statements.
continue	No	
default	No	
return	Yes, but with no return value.	

Conditional Statements in Macros

The conditional if-else-endif statement is allowed in macros. It works the same as in functions. See **If-Else-Endif** on page IV-30.

Loops in Macros

The do-while loop is supported in macros. It works the same as in functions. See **Do-While Loop** on page IV-34.

Return Statement in Macros

The return keyword immediately stops executing the current macro. If it was called by another macro, control returns to the calling macro.

A macro has no return value so return is used just to prematurely quit the macro. Most macros will have no return statement.

Invoking Macros

There are several ways to invoke a macro:

- From the command line
- From the Macros, Windows or user-defined menus
- From another macro
- From a button or other user control

The menu in which a macro appears, if any, is determined by the macro's type and subtype.

This table shows how a macro's type determines the menu that Igor puts it in.

Macro Type	Defining Keyword	Menu
Macro	Macro	Macros menu
Window Macro	Window	Windows menu
Proc	Proc	—

If a macro has a subtype, it may appear in a different menu. This is described under **Procedure Subtypes** on page IV-149. You can put macros in other menus as described in Chapter IV-5, **User-Defined Menus**.

You can not directly invoke a macro from a user function. You can invoke it indirectly, using the **Execute** operation (see page V-130).

Using \$ in Macros

As shown in the following example, the \$ operator can create references to global numeric and string variables as well as to waves.

```
Macro MacroTest(vStr, sStr, wStr)
    String vStr, sStr, wStr

    $vStr += 1
    $sStr += "Hello"
    $wStr += 1
End
```

```
Variable/G gVar = 0; String/G gStr = ""; Make/O/N=5 gWave = p
MacroTest("gVar", "gStr", "gWave")
```

See **String Substitution Using \$** on page IV-14 for additional examples using \$.

Waves as Parameters in Macros

The only way to pass a wave to a macro is to pass the name of the wave in a string parameter. You then use the \$ operator to convert the string into a wave reference. For example:

```
Macro PrintWaveStdDev(w)
    String w

    WaveStats/Q $w
    Print V_sdev
End

Make/O/N=100 test=gnoise(1)
Print NamedWaveStdDev("test")
```

The Missing Parameter Dialog

When a macro that is declared to take a set of input parameters is executed with some or all of the parameters missing, it displays a dialog in which the user can enter the missing values. For example:

```
Macro MacCalcDiag(x,y)
    Variable x=10,y=20
    Prompt x, "Enter X component: "      // set prompt for x param
    Prompt y, "Enter Y component: "      // set prompt for y param

    Print "diagonal=",sqrt(x^2+y^2)
End
```

The Prompt statements are also optional — if omitted, the variable name will be used as the prompt text.

There must be a blank line after the set of input parameter and prompt declarations and there must not be any blank lines within the set.

The missing parameter dialog supports the creation of pop-up menus as described under **Pop-Up Menus in Simple Dialogs** on page IV-105. One difference is that in a missing parameter dialog, the menu item list can be continued using as many lines as you need. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
"yellow;purple"
```

Macro Errors

Igor can find errors in macros at two times:

- When it scans the macros
- When it executes the macros

After you modify procedure text, scanning occurs when you activate a nonprocedure window, click the Compile button or choose Compile from the Macros menu. At this point, Igor is just looking for the names

of procedures. The only errors that it detects are name conflicts and ill-formed names. If it finds such an error, it displays a dialog that you use to fix it.

Igor detects other errors when the macro executes. Execution errors may be recoverable or nonrecoverable. If a recoverable error occurs, Igor puts up a dialog in which you can edit the erroneous line.

You can fix the error and retry or quit macro execution.

If the error is nonrecoverable, you get a similar dialog except that you can't fix the error and retry. This happens with errors in the parameter declarations and errors related to if-else-endif and do-while structures.

The Silent Option

Normally Igor displays each line of a macro in the command line as it executes the line. This gives you some idea of what is going on. However it also slows macro execution down considerably. You can prevent Igor from showing macro lines as they are executed by using the `Silent 1` command.

You can use `Silent 1` from the command line. It is more common to use it from within a macro. The effect of the `Silent` command ends at the end of the macro in which it occurs. Many macros contain the following line:

```
Silent 1; PauseUpdate
```

The Slow Option

You can observe the lines in a macro as they execute in the command line. However, for debugging purposes, they often whiz by too quickly. The `Slow` operation slows the lines down. It takes a parameter which controls how much the lines are slowed down. Typically, you would execute something like "`Slow 10`" from the command line and then "`Slow 0`" when you are finished debugging.

You can also use the `Slow` operation from within a macro. You must explicitly invoke "`Slow 0`" to revert to normal behavior. It does not automatically revert at the end of the macro from which it was invoked.

We never use this feature. Instead, we generally use print statements for debugging or we use the Igor symbolic debugger, described in Chapter IV-8, **Debugging**.

Accessing Variables Used by Igor Operations

A number of Igor's operations return results via variables. For example, the `WaveStats` operation creates a number of variables with names such as `V_avg`, `V_sigma`, etc.

When you invoke these operations from the command line, they create global variables in the current data folder. When you invoke them from a macro, they create local variables unless a global variable already exists. If both a global variable and a local variable exist, Igor uses the local variable.

In addition to creating variables, a few operations, such as CurveFit and FuncFit, check for the existence of specific variables to provide optional behavior. The operations look first for a local variable with a specific name. If the local variable is not found, they then look for a global variable.

Updates During Macro Execution

An update is an action that Igor performs. It consists of:

- Reexecuting assignments for dependent objects whose antecedents have changed (see Chapter IV-9, **Dependencies**);
- Redrawing graphs and tables which display waves that have changed;
- Redrawing page layouts containing graphs, tables, or annotations that have changed;
- Redrawing windows that have been uncovered.

When no procedure is executing, Igor continually checks whether an update is needed and does an update if necessary.

During macro execution, Igor checks if an update is needed after executing each line. You can suspend checking using the PauseUpdate operation. This is useful when you want an update to occur when a macro finishes but not during the course of the macro's execution.

PauseUpdate has effect only inside a macro. Here is how it is used.

```
Window Graph0() : Graph
    PauseUpdate; Silent 1
    Display /W=(5,42,400,250) w0,w1,w2
    ModifyGraph gFont="Helvetica"
    ModifyGraph rgb(w0)=(0,0,0),rgb(w1)=(0,65535,0),rgb(w2)=(0,0,0)
    <more modifies here...>
End
```

Without the PauseUpdate, Igor would do an update after each modify operation. This would take a long time.

At the end of the macro, Igor automatically reverts the state of update-checking to what it was when this macro was invoked. You can use the ResumeUpdate operation if you want to resume updates before the macro ends or you can call DoUpdate to force an update to occur at a particular point in the program flow. Such explicit updating is rarely needed.

Aborting Macros

There are two ways to prematurely stop macro execution: a user abort or a programmed abort. Both stop execution of all macros, no matter how deeply nested.

On Macintosh, you can abort macro execution by pressing Command-period. On Windows, press Ctrl+Break or click the Abort button in the status bar. You may need to hold the keys down for a while because Igor looks at the keyboard periodically and if you don't press the keys long enough, Igor will not see them.

On either platform, you can abort macro execution by choosing Abort Procedure Execution from the Macros menu.

A user abort does not directly return. What it does is set a flag that stops loops from looping and then returns using the normal calling chain. For this reason some code will still be executed after an abort but execution should stop quickly. This behavior releases any temporary memory allocations made during execution.

A **programmed abort** occurs when the Abort operation is executed. Here is an example:

```
if( numCells > 10 )
    Abort "Too many cells! Quitting."
endif
// code here doesn't execute if numCells > 10
```

Converting Macros to Functions

If you have old Igor procedures written as macros, as you have occasion to revisit them, you can consider converting them to functions. In most cases, this is a good idea. An exception is if the macros are so complex that there would be a substantial risk of introducing bugs. In this case, it is better to leave things as they are.

If you decide to do the conversion, here is a checklist that you can use in the process.

1. Back up the old version of the procedures.
2. Change the defining keyword from Macro or Proc to Function.
3. If the macro contained Prompt statements, then it was used to generate a missing parameter dialog. Change it to generate a simple input dialog as follows:
 - a. Remove the parameters from the parameter list. The old parameter declarations now become local variable declarations.
 - b. Make sure that the local variable for each prompt statement is initialized to some value.
 - c. Add a DoPrompt statement after all of the Prompt statements.
 - d. Add a test on V_Flag after the DoPrompt statement to see if the user canceled.
4. Look for statements that access global variables or strings and create NVAR and SVAR references for them.
5. Look for any waves used in assignment statements and create WAVE references for them.
6. Compile procedures. If you get an error, fix it and repeat step 6.

User-Defined Menus

Overview	88
Menu Definition Syntax	89

Enabling and Disabling Special Character Interpretation	98
Keyboard Shortcuts	99
Function Keys	100
Marquee Menus	100
Trace Menus	101

Overview

You can add your own menu items to many Igor menus by writing a menu definition in a procedure window. A simple menu definition looks like this:

```
Menu "Macros"  
    "Load Data File/1"  
    "Do Analysis/2"  
    "Print Report"  
End
```

This adds three items to the Macros menu. If you choose Load Data File or press Command-1 (*Macintosh*) or Ctrl+1 (*Windows*), Igor will execute the procedure LoadDataFile which, presumably, you have written in a procedure window. The command executed when you select a particular item is derived from the text of the item. This is an *implicit* specification of the item's execution text.

You can also *explicitly* specify the execution text:

```
Menu "Macros"  
    "Load Data File/1", Beep; LoadWave/G  
    "Do Analysis/2"  
    "Print Report"  
End
```

Now if you choose Load Data File, Igor will execute "Beep; LoadWave/G".

When you choose a user menu item, Igor checks to see if there is execution text for that item. If there is, Igor executes it. If not, Igor makes a procedure name from the menu item string. It does this by removing any characters that are not legal characters in a procedure name. Then it executes the procedure. For example, choosing an item that says

```
"Set Sampling Rate..."
```

executes the SetSamplingRate procedure.

If a procedure window is the top window and if Option (*Macintosh*) or Alt (*Windows*) is pressed when you choose a menu item, Igor tries to find the procedure in the window, rather than executing it.

A menu definition can add submenus as well as regular menu items.

```
Menu "Macros"  
    Submenu "Load Data File"  
        "Text File"  
        "Binary File"  
    End  
  
    Submenu "Do Analysis"  
        "Method A"  
        "Method B"  
    End  
  
    "Print Report"  
End
```

This adds three items to the Macros menu, two submenus and one regular item. You can nest submenus to any depth.

There are some limits to the number of menu items that you can add. Igor can handle no more than 100 user-defined main menus and not more than 200 user-defined submenus.

The user-defined menus added by procedure files opened in the current experiment (such as the Example Experiments menu item in the File menu added by the WMMenus.ipf procedure file in the Igor Procedures folder) count against those limits.

In the Windows version of Igor, there is also a limit of 31 items in a menu, and each special user-defined menu counts as several user-defined menus or submenus. For example, a `"*COLORPOP"` submenu counts as 6 submenus against the allowed 200. See **Specialized Menu Item Definitions** on page IV-94.

Menu Definition Syntax

The syntax for a menu definition is:

```
Menu <Menu title string>
  [<Menu help strings>]
  <Menu item string> [, <menu item flags>] [, <execution text>]
  [<Item help strings>]
  ...
  Submenu <Submenu title string>
    [<Submenu help strings>]
    <Submenu item string> [, <execution text>]
    [<Item help strings>]
  ...
End
End
```

`<Menu title string>` is the title of the menu to which you want to add items. Often this will be `Macros` but you can also add items to `Analysis`, `Misc` and many other built-in Igor menus, including some submenus and the graph marquee and layout marquee menus. If `<Menu title string>` is not the title of a built-in menu then Igor creates a new main menu on the menu bar.

`<Menu help strings>` specifies the help for the menu title. This is optional. See **Help for User Menus** on page IV-90 for details.

`<Menu item string>` is the text to appear for a single menu item, a semicolon-separated string list to define **Multiple Menu Items** (see page IV-93), or **Specialized Menu Item Definitions** (see page IV-94) such as a color, line style, or font menu.

`<Menu item flags>` are optional flags that modify the behavior of the menu item. The only flag currently supported is `/Q`, which prevents Igor from storing the executed command in the history area. This is useful for menu commands that are executed over and over through a keyboard shortcut. This feature was introduced in Igor Pro 5. Using it will cause errors in earlier versions of Igor.

`<Execution text>` is an Igor command to execute for the menu item. If omitted, Igor makes a procedure name from the menu item string and executes that procedure.

`<Item help strings>` specifies the help for the menu item. This is optional. It can appear after a main menu item or after a submenu item. See **Help for User Menus** on page IV-90 for details.

The `Submenu` keyword introduces a submenu with `<Submenu title string>` as its title. The submenu continues until the next `End` keyword.

`<Submenu item string>` acts just like `<Menu item string>`.

Built-in Menus That Can Be Extended

Here are the titles of built-in Igor menus to which you can add items.

Add Controls	AllTracesPopup	Analysis	Append to Graph	Control
Data	Edit	File	Graph	GraphMarquee
Help	Layout	LayoutMarquee	Load Waves	Macros
Misc	Statistics	New	Notebook	Open File
Panel	Procedure	Save Waves	Table	TracePopup

These menu titles must appear in double quotes when used in a menu definition.

Chapter IV-5 — User-Defined Menus

Use these menu titles to identify the menu to which you want to append items even if you are working with a version of Igor translated into a language other than English.

The GraphMarquee, LayoutMarquee, TracePopup, and AllTracesPopup menus are contextual menus. See **Marquee Menus** on page IV-100 and **Trace Menus** on page IV-101.

All other Igor menus, including menus added by XOPs, can not accept user-defined items.

The **HideIgorMenus** operation (see page V-215) and the **ShowIgorMenus** operation (see page V-511) hide or show most of the built-in main menus (not the Marquee and Popup menus). User-defined menus that add items to built-in menus are normally not hidden or shown by these operations. When a built-in menu is hidden, the user-defined menu items create a user-defined menu with only user-defined items. For example, this user-defined menu:

```
Menu "Table"
    "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"
End
```

will create a Table menu with only one item in it after the HideIgorMenus "Table" command is executed.

To have your user-defined menu items hidden along with the built-in menu items, add the **hideable** keyword after the Menu definition:

```
Menu "Table", hideable
    "Append Columns to Table...", DoIgorMenu "Table", "Append Columns to Table"
End
```

Adding a New Main Menu

You can add an entirely new menu to the main menu bar by using a menu title that is not used by Igor. For example:

```
Menu "Test"
    "Load Data File"
    "Do Analysis"
    "Print Report"
End
```

Help for User Menus

You can specify help for the menus and menu items that you define. On Mac OS X, the help text appears if you enable Igor Tips through the Help menu. On Windows, Igor uses the help text to provide status line help.

```
Menu "Test"
    help = {"This is the help for the Test menu."}

    "Load Data File"
    help = {"This is the help for the Load Data File item."}

    "Do Analysis"
    help = {"This is the help for the Do Analysis item."}

    "Print Report"
    help = {"This is the help for the Print Report item."}
End
```

The first help line specifies the help text for the menu title. The subsequent lines specify the help text to appear for the respective menu items.

On Macintosh, help does not appear for menu and submenu titles. It does appear over menu and submenu items.

Because of technical difficulties, help for user-defined items in the Edit menu will not appear. Also, on Macintosh, help for user-defined items in the Help menu will not appear.

The full form of the menu help specification is:

```
help = {"String 1", "String 2", "String 3", "String 4"}
```

String 1 supplies the text to appear when the menu or menu item is enabled. String 2 supplies the text to appear when the menu or menu item is disabled. String 3 supplies the text to appear when the menu or menu item is checked. String 4 supplies the text to appear when the menu or menu item is marked with a marker other than check.

If you omit one or more of these strings, Igor uses the text for string 1 for the corresponding state. Thus, the following are equivalent:

```
help = {"Test 1", "Test 2", "Test 1", "Test 1"}
help = {"Test 1", "Test 2"}
```

In most cases, it will be sufficient to provide just the text for the enabled state since you will most likely not go to the trouble of enabling, disabling or checking your menu items.

Dynamic Menu Items

In the examples shown so far all of the user-defined menu items are static. Once defined, they never change. This is sufficient for the vast majority of cases and is by far the easiest way to define menu items.

Igor also provides support for dynamic user-defined menu items. A dynamic menu item changes depending on circumstances. The item might be enabled under some circumstances and disabled under others. It might be checked or deselected. Its text may toggle between two states (e.g. "Show Tools" and "Hide Tools").

Because dynamic menus are much more difficult to program than static menus and also slow down Igor's response to a menu-click, we recommend that you keep your use of dynamic menus to a minimum. The effort you expend to make your menu items dynamic may not be worth the time you spend to do it.

For a menu item to be dynamic, you must define it using a string expression instead of the literal strings used so far. Here is an example.

```
Function DoAnalysis()
    Print "Analysis Done"
End

Function ToggleTurboMode()
    Variable prevMode = NumVarOrDefault("root:gTurboMode", 0)
    Variable/G root:gTurboMode = !prevMode
End

Function/S MacrosMenuItem(itemNumber)
    Variable itemNumber

    Variable turbo = NumVarOrDefault("root:gTurboMode", 0)

    if (itemNumber == 1)
        if (strlen(WaveList("*", ";", ""))=0) // any waves exist?
            return "(Do Analysis" // disabled state
        else
            return "Do Analysis" // enabled state
        endif
    endif

    if (itemNumber == 2)
        if (turbo)
            return "!" + num2char(18) + "Turbo" // Turbo with a check
        else
            return "Turbo"
        endif
    endif
end
```

```
endif
End

Menu "Macros", dynamic
  MacrosMenuItem(1)
  help= {"Do analysis", "Not available because there are no waves."}

  MacrosMenuItem(2), /Q, ToggleTurboMode()
  help= {"When checked, turbo mode is on."}
End
```

In this example, the text for the menu item is computed by the `MacrosMenuItem` function. It computes text for item 1 and for item 2 of the menu. Item 1 can be enabled or disabled. Item 2 can be checked or unchecked.

The `dynamic` keyword specifies that the menu definition contains a string expression that needs to be reevaluated each time the menu item is drawn. This rebuilds the user-defined menu each time the user clicks in the menu bar. Under the current implementation, *all* user menus are rebuilt each time the user clicks in the menu bar if *any* user-defined menu is declared dynamic. If you use a large number of user-defined items, the time to rebuild the menu items may be noticeable.

There is another technique for making menu items change. You define a menu item using a string expression rather than a literal string but you do not declare the menu dynamic. Instead, you call the `BuildMenu` operation whenever you need the menu item to be rebuilt. Here is an example:

```
Function ToggleItem1()
  String item1Str = StrVarOrDefault("root:MacrosItem1Str","On")
  if (CmpStr(item1Str,"On") == 0)      // Item is now "On"?
    String/G root:MacrosItem1Str = "Off"
  else
    String/G root:MacrosItem1Str = "On"
  endif
  BuildMenu "Macros"
End

Menu "Macros"
  StrVarOrDefault("root:MacrosItem1Str","On"), /Q, ToggleItem1()
End
```

Here, the menu item is controlled by the global string variable `MacrosItem1Str`. When the user chooses the menu item, the `ToggleItem1` function runs. This function changes the `MacrosItem1Str` string and then calls `BuildMenu`, which rebuilds the user-defined menu the next time the user clicks in the menu bar. Under the current implementation, Igor will rebuild *all* user-defined menus if `BuildMenu` is called for *any* user-defined menu.

Optional Menu Items

A dynamic user-defined menu item *disappears* from the menu if the menu item string expression evaluates to `""`; the remainder of the menu definition line is then ignored. This makes possible a variable number of items in a user-defined menu list. This example adds a menu listing the names of up to 8 waves in the current data folder. If the current data folder contains less than 8 waves, then only those that exist are shown in the menu:

```
Menu "Waves", dynamic
  WaveName(" ",0,4), DoSomething($WaveName(" ",0,4))
  WaveName(" ",1,4), DoSomething($WaveName(" ",1,4))
  WaveName(" ",2,4), DoSomething($WaveName(" ",2,4))
  WaveName(" ",3,4), DoSomething($WaveName(" ",3,4))
  WaveName(" ",4,4), DoSomething($WaveName(" ",4,4))
  WaveName(" ",5,4), DoSomething($WaveName(" ",5,4))
  WaveName(" ",6,4), DoSomething($WaveName(" ",6,4))
  WaveName(" ",7,4), DoSomething($WaveName(" ",7,4))
End

Function DoSomething(w)
  Wave/Z w
```

```

    if( WaveExists(w) )
        Print "DoSomething: wave's name is "+NameOfWave(w)
    endif
End

```

This works because WaveName returns "" if the indexed wave doesn't exist.

Note that each potential item must have a menu definition line that either appears or disappears.

Multiple Menu Items

A menu item string that contains a semicolon-separated "string list" (see **StringFromList** on page V-603) generates a menu item for each item in the list. For example:

```

Menu "Multi-Menu"
    "first item;second item;", DoItem()
End

```

Multi-Menu will be a two-item menu. When either item is selected the DoItem procedure is called.

This begs the question: How does the DoItem procedure know which item was selected? The answer is that DoItem must call the **GetLastUserMenuInfo** operation (see page V-191) and examine the appropriate returned variables, usually V_value (the selected item's number, 1 for the first item, 2 for the second, etc.) or S_Value (the selected item's text).

The string list can be dynamic, too. The above "Waves" example can be rewritten to handle an arbitrary number of waves (maximum 31 on Windows) using this definition:

```

Menu "Waves", dynamic
    WaveList("*,",",",""), DoItem()
End

Function DoItem()
    GetLastUserMenuInfo          // sets S_value, V_value, etc.
    WAVE/Z w= $S_value
    if( WaveExists(w) )
        Print "The wave's name is "+NameOfWave(w)
    endif
End

```

Consolidating Menu Items Into a Submenu

It is common to have many utility procedure files open at the same time. Each procedure file could add menu items which would clutter Igor's menus. When you create a utility procedure file that adds multiple menu items, it is usually a good idea to consolidate all of the menu items into one submenu. Here is an example.

Let's say we have a procedure file full of utilities for doing frequency-domain data analysis and that it contains the following:

```

Function ParzenDialog()
    ...
End

Function WelchDialog()
    ...
End

Function KaiserDialog()
    ...
End

```

We can consolidate all of the menu items into a single submenu in the Analysis menu:

```
Menu "Analysis"  
  Submenu "Windows"  
    "Parzen...", ParzenDialog()  
    "Welch...", WelchDialog()  
    "Kaiser...", KaiserDialog()  
  End  
End
```

Specialized Menu Item Definitions

A menu item string that contains certain special values adds a specialized menu such as a color menu.

Only one specialized menu item string is allowed in each menu or submenu, it must be the first item, and it must be the only item.

Menu Item String	Result
"*CHARACTER"	"Character menu, no character is initially selected, font is Geneva, font size is 12. See Menu Limits on page IV-95 for *CHARACTER* menu limitations.
"*CHARACTER*(Symbol)"	"Character menu of Symbol font.
"*CHARACTER*(Symbol,36)"	"Character menu of Symbol font in 36 point size.
"*CHARACTER*(,36)"	"Character menu of Geneva font in 36 point size.
"*CHARACTER*(Symbol,36,p)"	"Character menu of Symbol font in 36 point size, initial character is p (π).
"*COLORTABLEPOP"	"Color table menu, initial table is Grays.
"*COLORTABLEPOP*(YellowHot)"	"Color table menu, initial table is YellowHot. See CTabList on page V-73 for a list of color tables.
"*COLORTABLEPOP*(YellowHot,1)"	"Color table menu with the colors drawn reversed.
"*COLORPOP"	"Color menu, initial color is black.
"*COLORPOP*(0,65535,0)"	"Color menu, initial color is green.
"*FONT"	"Font menu, no font is initially selected, does not include "default" as a font choice. See Menu Limits on page IV-95 for *FONT* menu limitations.
"*FONT*(Arial)"	"Font menu, Arial is initially selected.
"*FONT*(Arial,default)"	"Font menu with Arial initially selected and including "default" as a font choice.
"*LINESTYLEPOP"	"Line style menu, no line style is initially selected.
"*LINESTYLEPOP*(3)"	"Line style menu, initial line style is style=3 (coarse dashed line).
"*MARKERPOP"	"Marker menu, no marker is initially selected.
"*MARKERPOP*(8)"	"Marker menu, initial marker is 8 (empty circle).
"*PATTERNPOP"	"Pattern menu, no pattern is initially selected.
"*PATTERNPOP*(1)"	"Pattern menu, initial pattern is 1 (SW-NE light diagonal).

To retrieve the selected color, line style, etc., the execution text must be a procedure that calls the **GetLastUserMenuInfo** operation (see page V-191). Here's an example of a color submenu implementation:

```
Menu "Main", dynamic  
  "First Item", /Q, HandleFirstItem()  
  Submenu "Color"  
    CurrentColor(), /Q, SetSelectedColor() // must be first item
```

```

// can't add items here
End
"Third Item", /Q, HandleThirdItem()
End

Function/S CurrentColor()
Variable/G root:red, root:green, root:blue
NVAR red= root:red
NVAR green= root:green
NVAR blue= root:blue
String menuText
sprintf menuText, "*COLORPOP*(%d,%d,%d)", red, green, blue
return menuText
End

Function SetSelectedColor()
GetLastUserMenuInfo // sets V_red, V_green, V_blue, S_value, V_value
Variable/G root:red= V_red
Variable/G root:green= V_green
Variable/G root:blue= V_blue

Make/O/N=(2,2,3) root:colorSpot
Wave colorSpot= root:colorSpot
colorSpot[0][0]= V_red
colorSpot[0][1]= V_green
colorSpot[0][2]= V_blue

CheckDisplayed/A colorSpot
if( V_Flag == 0 )
    NewImage colorSpot
endif
End

```

Menu Limits

Although the maximum font size allowed is 99, the *CHARACTER* menus are limited to about 800 pixels wide by 600 pixels high and most font sizes above 48 or so don't increase the font size of the displayed characters.

The *FONT* menus are quite different on Macintosh and Windows.

The Macintosh menu is just a long menu of all the fonts, optionally with "default" at the bottom.

On Windows, menus are limited to 31 items. If you specify just "*FONT*", the resulting menu item has just a "Font..." item. You can list up to 28 font names including the initially-selected font (the first one listed) and optionally a divider represented by "-". "default" can be one of the listed font names. A "Font..." item always appears in the menu to select any installed font. Fonts that you list but which are not installed are ignored and won't appear in the menu. Those that do appear are sorted alphabetically. For example:

```

Menu " Font" // (The "Font" menu is restricted, but " Font" isn't)
    "*FONT*(Times New Roman,default,Arial,Webdings,Symbol)", DoFont()
End

Function DoFont()
    GetLastUserMenuInfo
    Print S_value
End

```

produces a Font menu with "Orange LET" initially selected and all the listed fonts as (sorted) font choices:

On Windows, most specialized menu items count as more than one menu against the limits of 100 user-defined main menus or 200 user-defined submenus:

Menu Kind	Effective Number of Menus (Windows only)
"*FONT*	1
"*LINESTYLEPOP*	1
"*PATTERNPOP*	3
"*MARKERPOP*	2
"*CHARACTER*	8
"*COLORPOP*	6
"*COLORTABLEPOP*	2

Special Characters in Menu Item Strings

You can control some aspects of a menu item by using special characters. These special characters are based on the behavior of the Macintosh menu manager and are only partially supported on Windows (see **Special Menu Characters on Windows** on page IV-97). They affect user-defined menus in the main menu bar. On Macintosh, but not on Windows, they also affect user-defined pop-up menus in control panels, graphs and simple input dialogs.

By default, special character interpretation is enabled in user-defined menu bar menus and is disabled in user-defined control panel, graph and simple input dialog pop-up menus. This is almost always what you would want. In some cases, you might want to override the default behavior. This is discussed under **Enabling and Disabling Special Character Interpretation** on page IV-98.

This table shows the special characters and their effect if special character interpretation is enabled. See **Special Menu Characters on Windows** on page IV-97 for Windows-specific considerations.

Character	Behavior
/	<p>Creates a keyboard shortcut for the menu item.</p> <p>The character after the slash defines the item's keyboard shortcut. For example, "Low Pass/1" makes the item "Low Pass" with a keyboard shortcut for Command-1 (<i>Macintosh</i>) or Ctrl-1 (<i>Windows</i>). You can also use function keys. To avoid conflicts with Igor, use the numeric keys and the function keys only. See Keyboard Shortcuts on page IV-99 and Function Keys on page IV-100 for further details.</p> <p>Keyboard shortcuts are not supported in the graph marquee and layout marquee menus.</p>
-	<p>Creates a divider between menu items.</p> <p>If a hyphen (minus sign) is the first character in the item then the item will be a disabled divider. This can be a problem when trying to put negative numbers in a menu. Use a leading space character to prevent this. The string "(-" also disables the corresponding divider.</p>
(<p>Disables the menu item.</p> <p>If a left parenthesis appears anywhere in the item then the item will be disabled.</p>

Character	Behavior
!	<p>Adds a mark to the menu item.</p> <p>If an exclamation point appears in the item, the character after the exclamation point will appear to the left of the menu item. For example, "Low Pass!*" makes an item "Low Pass" with an asterisk to the left. To mark an item with a check, use</p> <pre>"Low Pass!" + num2char(18)</pre> <p>This is necessary because the character code (18) for a check mark is a nonprinting control character that is not displayed correctly in most fonts.</p>
<	<p>Controls the typographic style of the item.</p> <p>This is rarely used since it tends to make the menu too garish.</p>
^	<p>Draws an icon as the menu item.</p> <p>This is not supported in Igor. Do not use it.</p>
;	<p>Separates one menu item from the next.</p> <p>Example: "Item 1;Item 2"</p>

Whereas it is standard practice to use a semicolon to separate items in a pop-up menu in a control panel, graph or simple input dialog, you should avoid using the semicolon in user-defined main-menu-bar menus. It is clearer if you use one item per line. It is also necessary in some cases (see **Menu Definition Syntax** on page IV-89).

If a left angle bracket appears in the item, then the style of type for the item is controlled by the character following the angle bracket as follows:

Character Sequence	Makes Item
<B	bold
<I	italic
<U	underlined
<O	outlined
<S	shadowed

For example, "Low Pass<U" makes the item "Low Pass" with an underline.

If special character interpretation is disabled, these characters will appear in the menu item instead of having their special effect. The semicolon character is treated as a separator of menu items even if special character interpretation is disabled.

Special Menu Characters on Windows

On Windows, these characters are treated as special in menu bar menus but not in pop-up menus in graphs, control panels, and simple input dialogs. The following table shows which special characters are supported.

Character	Meaning	Status
/	Defines accelerator	Supported
-	Divider	Supported
(Disables item	Supported
!	Adds mark to item	Partially supported — see discussion below
<	Controls typography	Not supported — ignored
^	Specifies icon	Not supported — ignored
;	Separates items	Supported

Chapter IV-5 — User-Defined Menus

Windows does not directly support marking a menu item with anything other than a checkmark. Therefore, on Windows, when Igor sees the "!" special character, it checks the menu item regardless of which character follows the "!". The following user-defined menu item definition will produce a checked item on both platforms:

```
"Test!" + num2char(18)
```

"num2char(18)" returns the character code for a check mark on the Macintosh.

In general, Windows does not allow using Ctrl+<punctuation> as an accelerator. Therefore, in the following example, the accelerator will not do anything:

```
Menu "Macros"  
  "Test/[ "          // "[/" will not work on Windows.  
End
```

On Windows, you can designate a character in a menu item as a mnemonic keystroke by preceding the character with an ampersand:

```
Menu "Macros"  
  "&Test", Print "This is a test"  
End
```

This designates "T" as the mnemonic keystroke for Test. To invoke this menu item, press Alt and release it, press the "M" key to highlight the Macros menu, and press the "T" key to invoke the Test item. If you hold the Alt key pressed while pressing the "M" and "T" keys and if the active window is a procedure window, Igor will not execute the item's command but rather will bring up the procedure window and display the menu definition. This is a programmer's shortcut.

Note: The mnemonic keystroke is not supported on Macintosh. If you use an ampersand in a menu item, it will appear in the menu item on the Macintosh. For this reason, if you care about cross-platform compatibility, you should not use ampersands in your menu items.

Enabling and Disabling Special Character Interpretation

The interpretation of special characters in menu items can sometimes get in the way. For example, you may want a menu item to say "m/s" or "A<B". With special character interpretation enabled, the first of these would become "m" with "s" as the keyboard shortcut and the second would become "A" in a bold typeface.

Igor provides WaveMetrics-defined escape sequences that allow you to override the default state of special character interpretation. These escape sequences are case sensitive and must appear at the very start of the menu item:

Escape Code	Effect	Example	
"\\M0"	Turns special character interpretation off.	"\\M0m/s"	<div>m/s</div> <div>m/s</div>
"\\M1"	Turns special character interpretation on.	"\\M1m/s"	<div>m ⌘s</div> <div>m Ctrl+s</div>

The most common use for this will be in a user-defined menu bar menu in which the default state is on and you want to display a special character in the menu item text itself. That is what you can do with the "\\M0" escape sequence.

Another possible use on Macintosh is to create a disabled menu item in a control panel, graph or simple input dialog pop-up menu. The default state of special character interpretation in pop-up menus is off. To disable the item, you either need to turn it on, using "\\M1" or to use the technique described in the next paragraph.

What if we want to include a special character in the menu item itself *and* have a keyboard shortcut for that item? The first desire requires that we turn special character interpretation off and the second requires that we turn it on. The WaveMetrics-defined escape sequence can be extended to handle this. For example:

```
"\\M0:/1:m/s"
```

The initial "\\M0" turns normal special character interpretation off. The first colon specifies that one or more special characters are coming. The /1 makes Command-1 (*Macintosh*) or Ctrl+1 (*Windows*) the keyboard shortcut for this item. The second colon marks the end of the menu commands and starts the regular menu text which is displayed in the menu without special character interpretation. The final result is as shown above.

Any of the special characters can appear between the first colon and the second. For example:

```
Menu "Macros"
  "\\M0:/1:(Cmd key)"
  "\\M0::(Disabled item)"
  "\\M0:!*: (Marked with *)"
  "\\M0:/2!*: (Cmd key plus *)"
End
```

```
Menu "Macros"
  "\\M0:/1:(Ctrl key)"
  "\\M0::(Disabled item)"
  "\\M0:!" + num2char(18) + ": (Marked with a check)"
  "\\M0:/2!" + num2char(18) + ": (Ctrl key plus check)"
End
```

The \\M escape code affects just the menu item currently being defined. In the following example, special character interpretation is enabled for the first item but not for the second:

```
"\\M1(First item;(Second item)"
```

To enable special character interpretation for both items, we need to write:

```
"\\M1(First item;\\M1(Second item)"
```

Keyboard Shortcuts

A keyboard shortcut is a set of one or more keys which invoke a menu item. In a menu item string, a keyboard shortcut is introduced by the / special character. For example:

```
Menu "Macros"
  "Test/1"          // The keyboard shortcut is Cmd-1 (Macintosh)
End                 // or Ctrl-1 (Windows).
```

All of the alphabetic keyboard shortcuts (/A.../Z) are used by Igor. Numeric keyboard shortcuts (/0.../9) are available for use in user menu definitions as are Function Keys, described below.

You can define a numeric keyboard shortcut that includes one or more modifier keys. The modifier keys are Shift and Option (*Macintosh*) or Alt (*Windows*). For example:

```
Menu "Macros"
  "Test/1"          // Cmd-1, Ctrl-1
  "Test/S1"         // Shift-Cmd-1, Ctrl-Shift-1.
  "Test/O1"         // Option-Cmd-1, Ctrl-Alt-1
  "Test/OS1"        // Option-Shift-Cmd-1, Ctrl-Shift-Alt-1
End
```

On Macintosh, "L" can be used to indicate that the Control key must be pressed. This is not supported on Windows.

Function Keys

Most keyboards have function keys labeled F1 through F12. In Igor, you can treat a function key as a keyboard shortcut that invokes a menu item.

Note: Mac OS X reserves nearly all function keys for itself. In order to use function keys for an application, you must check a checkbox in the Keyboard control panel. Even then the OS will intercept some function keys.

Note: On Windows, Igor uses F1 for help-related operations. F1 will not work as a keyboard shortcut on Windows. Also, the Windows OS reserves Ctrl-F4 and Ctrl-F6 for closing and reordering windows.

Here is a simple function key example:

```
Menu "Macros"  
  "Test/F5"      // The keyboard shortcut is F5.  
End
```

As with other keyboard shortcuts, you can specify that one or more modifier keys must be pressed along with the function key. The modifier keys are Shift and Option (*Macintosh*) or Alt (*Windows*).

```
Menu "Macros"  
  // Function keys with and without modifiers  
  "Test/F5"      // F5  
  "Test/SF5"     // Shift-F5  
  "Test/OF5"     // Option-F5, Alt-F5  
  "Test/SOF5"    // Shift-Option-F5, Shift-Alt-F5  
End
```

By including the “C” modifier character, you specify that the Command (*Macintosh*) or Ctrl (*Windows*) key must also be pressed:

```
Menu "Macros"  
  // Cmd-Function or Ctrl-Function keys with and without modifiers  
  "Test/CF5"     // Cmd-F5, Ctrl-F5  
  "Test/SCF5"    // Shift-Cmd-F5, Ctrl-Shift-F5  
  "Test/OCF5"    // Option-Cmd-F5, Ctrl-Alt-F5  
  "Test/OSCF5"   // Option-Shift-Cmd-F5, Ctrl-Shift-Alt-F5  
End
```

On Macintosh only, you can also use Control as a modifier by adding an “L” between the slash and the “F5”.

Although some keyboards have function keys labeled F13 and higher, they do not behave consistently and are not supported.

Marquee Menus

Igor has two menus called “marquee menus”. In graphs and page layouts you create a marquee when you drag diagonally. Igor displays a dashed-line box indicating the area of the graph or layout that you have selected. If you click inside the marquee, you get a marquee menu.

You can add your own menu items to a marquee menu by creating a GraphMarquee or LayoutMarquee menu definition. For example:

```
Menu "GraphMarquee"  
  "Print Marquee Coordinates", GetMarquee bottom; Print V_left, V_right  
End
```

The use of keyboard shortcuts is not supported in marquee menus.

See **Marquee Menu as Input Device** on page IV-115 for details.

Trace Menus

Igor has two “trace” menus named “TracePopup” and “AllTracesPopup”. When you control-click or right-click in a graph on a trace you get the TracesPopupMenu. If you hold down Shift while clicking, you get the AllTracesPopup (standard menu items in that menu operated on all the traces in the graph). You can append menu items to these menus with Menu “TracePopup” and Menu “AllTracesPopup” definitions.

For example:

```
Menu "TracePopup"  
    "IdentifyTrace", /Q, IdentifyTrace()  
End  
  
Function IdentifyTrace()  
    GetLastUserMenuInfo  
    Print S_graphName, S_traceName  
End
```

Cursors as Input Device	114
Marquee Menu as Input Device	115
Polygon as Input Device	115

Overview

The following sections describe the various programming techniques available for getting input from and for interacting with a user during the execution of your procedures. These techniques include:

- The simple input dialog
- Control panels
- Cursors
- Marquee menus

The simple input dialog provides a bare bones but functional user interfaces with just a little programming. In situations where more elegance is required, control panels provide a better solution.

Modal and Modeless User Interface Techniques

Before the rise of the graphical user interface, computer programs worked something like this: The user would start the program which would then ask the user for input. The program would then do some processing, after which it would ask the user for more input. In this model, the program is in charge and the user must respond with specific input at specific points of program execution. This is called a “modal” user interface because the program has one mode in which it will only accept specific input and another mode in which it will only do processing.

The Macintosh changed all this with the idea of event-driven programming. In this model, the computer waits for an event such as a mouse click or a key press and then acts on that event. The user is in charge and the program responds. This is called a “modeless” user interface because the program will accept any user action at any time.

You can use both techniques in Igor. Your program can put up a modal dialog asking for input and then do its processing or you can use control panels to build a sophisticated modeless event-driven system.

Event-driven programming is quite a bit more work than dialog-driven programming. You have to be able to handle user actions in any order rather than progressing through a predefined sequence of steps. In real life, a combination of these two methods is often used.

The Simple Input Dialog

The simple input dialog is a way by which a function can get input from the user in a modal fashion. It is very simple to program and is also somewhat simple in appearance.

A simple input dialog is presented to the user when a DoPrompt statement is executed in a function. Parameters to DoPrompt specify the title for the dialog and a list of local variables. For each variable, you must include a Prompt statement that provides the text label for the variable.

Generally, the simple input dialog is used in conjunction with routines that run when the user chooses an item from a menu. This is illustrated in the following example which you can type into the procedure window of a new experiment:

```
Menu "Macros"
    "Calculate Diagonal...", CalcDiagDialog()
End

Function CalcDiagDialog()
    Variable x=10,y=20
    Prompt x, "Enter X component: " // Set prompt for x param
    Prompt y, "Enter Y component: " // Set prompt for y param
    DoPrompt "Enter X and Y", x, y
    if (V_Flag)
        return -1 // User canceled
    endif
```

```
Print "Diagonal=",sqrt(x^2+y^2)
End
```

If you run the CalcDiagDialog function, you will see the following dialog:

If the user presses Continue without changing the default values, “Diagonal= 22.3607” will be printed in the history. If the user presses Cancel, nothing will be printed because DoPrompt sets the V_Flag variable to 1 in this case.

The simple input dialog allows for up to 10 numeric or string variables. When more than 5 items are used, the dialog uses two columns and you may have to limit the length of your Prompt text.

The simple input dialog is unique in that you can enter not only literal numbers or strings but also numeric expressions or string expressions. Any literal strings that you enter must be quoted.

If the user presses the Help button, Igor will search for a help topic with a name derived from the dialog title. If such a help topic is not found, then generic help about the simple input dialog will be presented. In both cases, the input dialog will remain until the user presses either Continue or Cancel.

Pop-Up Menus in Simple Dialogs

The simple input dialog supports pop-up menus as well as text items. The pop-up menus can contain an arbitrary list of items such as a list of wave names. To use a pop-up menu in place of the normal text entry item in the dialog, you use the following syntax in the prompt declaration:

```
Prompt <variable name>, <title string>, popup <menu item list>
```

The popup keyword indicates that you want a pop-up menu instead of the normal text entry item. The menu list specifies the items in the pop-up menu separated by semicolons. For example:

```
Prompt color, "Select Color", popup "red;green;blue;"
```

If the menu item list is too long to fit on one line, you can compose the list in a string variable like so:

```
String stmp= "red;green;blue;"
stmp += "yellow;purple"
Prompt color, "Select Color", popup stmp
```

The pop-up menu items support the same special characters as the user-defined menu definition (see **Special Characters in Menu Item Strings** on page IV-96) except that items in pop-up menus are limited to 50 characters, keyboard shortcuts are not supported, and special characters are disabled by default.

You can use pop-up menus with both numeric and string parameters. When used with numeric parameters the number of the item chosen is placed in the variable. Numbering starts from one. When used with string parameters the text of the chosen item is placed in the string variable.

There are a number of functions, such as the **WaveList** function (see page V-647) and the **TraceNameList** function (see page V-635), that are useful in creating pop-up menus.

To obtain a menu item list of all waves in the current data folder, use:

```
WaveList("*", ";", "")
```

To obtain a menu item list of all waves in the current data folder whose names end in “_X”, use:

```
WaveList("*_X", ";", "")
```

Chapter IV-6 — Interacting with the User

To obtain a menu item list of all traces in the top graph, use:

```
TraceNameList("", ";", 1)
```

For a list of all contours in the top graph, use ContourNameList. For a list of all images, use ImageNameList. For a list of waves in a table, use WaveList.

This next example creates two pop-up menus in the simple input dialog.

```
Menu "Macros"
    "Color Trace...", ColorTraceDialog()
End

Function ColorTraceDialog()
    String traceName
    Variable color=3
    Prompt traceName, "Trace", popup, TraceNameList("", ";", 1)
    Prompt color, "Color", popup, "red;green;blue"
    DoPrompt "Color Trace", traceName, color
    if( V_Flag )
        return 0          // user canceled
    endif

    if (color == 1)
        ModifyGraph rgb($traceName)=(65000, 0, 0)
    elseif(color == 2)
        ModifyGraph rgb($traceName)=(0, 65000, 0)
    elseif(color == 3)
        ModifyGraph rgb($traceName)=(0, 0, 65000)
    endif
End
```

If you choose Color Trace from the Macros menu, Igor brings up the simple input dialog with two pop-up menus. The first menu contains a list of all traces in the target window which is assumed to be a graph. The second menu contains the items red, green and blue with blue (item number 3) initially chosen.

After you choose the desired trace and color from the pop-up menus and click the Continue button, the function continues execution. The string parameter traceName will contain the name of the trace chosen from the first pop-up menu. The numeric parameter color will have a value of 1, 2 or 3, corresponding to red, green and blue.

In the preceding example, we needed a trace name to pass to the ModifyGraph operation. In another common situation, we need a wave reference to operate on. For example:

```
Menu "Macros"
    "Smooth Wave In Graph...", SmoothWaveInGraphDialog()
End

Function SmoothWaveInGraphDialog()
    String traceName
    Prompt traceName, "Wave", popup, TraceNameList("", ";", 1)
    DoPrompt "Smooth Wave In Graph", traceName
```

```

    WAVE w = TraceNameToWaveRef("", traceName)
    Smooth 5, w
End

```

The `traceName` parameter alone is not sufficient to specify which wave we want to smooth because it does not identify in which data folder the wave resides. The `TraceNameToWaveRef` function returns a wave reference which solves this problem. See **Wave Reference Functions** on page IV-143 for details.

Saving Parameters for Reuse

It is possible to write a procedure that presents a simple input dialog with default values for the parameters saved from the last time it was invoked. To accomplish this, we use global variables to store the values between calls to the procedure. Here is an example that saves one numeric and one string variable.

```

Function TestDialog()
    String savDF = GetDataFolder(1)
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S :TestDialog

    Variable num = NumVarOrDefault("gNum", 42)
    Prompt num, "Enter a number"
    String str = StrVarOrDefault("gStr", "Hello")
    Prompt str, "Enter a string"
    DoPrompt "test", num, str

    Variable/G gNum = num          // Save for next time
    String/G gStr = str

    // Put function body here
    Print num, str

    SetDataFolder savDF
End

```

This example illustrates the `NumVarOrDefault` and `StrVarOrDefault` functions. These functions return the value of a global variable or a default value if the global variable does not exist. 42 is the default value for `gNum`. `NumVarOrDefault` will return 42 if `gNum` does not exist. If `gNum` does exist, it will return the value of `gNum`. Similarly, "Hello" is the default value for `gStr`. `StrVarOrDefault` will return "Hello" if `gStr` does not exist. If `gStr` does exist, it will return the value of `gStr`.

Multiple Simple Input Dialogs

Prompt statements can be located anywhere within the body of a function and they do not need to be grouped together, although it will aid code readability if associated Prompt and DoPrompt code is kept together. Functions may contain multiple DoPrompt statements, and Prompt statements can be reused or redefined.

The following example illustrates multiple simple input dialogs and prompt reuse:

```

Function Example()
    Variable a= 123
    Variable/C ca= cmplx(3,4)
    String s

    Prompt a, "Enter a value"
    Prompt ca, "Enter complex value"
    Prompt s, "Enter a string", popup "red;green;blue"
    DoPrompt "Enter Values", a, s, ca
    if(V_Flag)
        Abort "The user pressed Cancel"
    endif

    Print "a= ", a, "s= ", s, "ca=", ca

```

```
Prompt a,"Enter a again please"
Prompt s,"Type a string"
DoPrompt "Enter Values Again", a,s

if(V_Flag)
    Abort "The user pressed Cancel"
endif

Print "Now a=",a," and s=",s
End
```

When this function is executed, it will produce two simple input dialogs, one after the other after the user clicks Continue; following is the first dialog:

Pause For User

The **PauseForUser** operation (see page V-420) allows an advanced programmer to create a more sophisticated semimodal user interface. When you invoke it from a procedure, Igor suspends procedure execution and the user can interact with graph, table or control panel windows using the mouse or keyboard. Execution continues when the user kills the main window specified in the **PauseForUser** command.

Pausing execution can serve two purposes. First, the programmer can pause function execution so that the user can, for example, adjust cursors in a graph window before continuing with a curve fit. In this application, the programmer creates a control panel with a continue button that the user presses after adjusting the cursors in the target graph. Pressing the continue button kills the host control panel (see example below).

In the second application, the programmer may wish to obtain input from the user in a more sophisticated manner than can be done using **DoPrompt** commands. This method uses a control panel as the main window with no optional target window. It is similar to the control panel technique shown above, except that it is modal.

Following are some examples of how you can use the **PauseForUser** operation (see page V-420) in your own user functions.

PauseForUser Simple Cursor Example

This example is a handy function that you can use to put up a panel that instructs the user to adjust the cursors and then click continue. Before calling this function, you need to make sure the target graph exists and has cursors showing.

```
Function UserCursorAdjust(grfName)
    String grfName

    DoWindow/F $grfName           // Bring graph to front
    if (V_Flag == 0)              // Verify that graph exists
        Abort "UserCursorAdjust: No such graph."
        return -1
    endif

    NewPanel/K=2 /W=(139,341,382,432) as "Pause for Cursor"
    DoWindow/C tmp_PauseforCursor // Set to an unlikely name
    AutoPositionWindow/E/M=1/R=$grfName // Put panel near the graph
```

```

    DrawText 21,20,"Adjust the cursors and then"
    DrawText 21,40,"Click Continue."
    Button button0,pos={80,58},size={92,20},title="Continue"
    Button button0,proc=UserCursorAdjust_ContButtonProc

    PauseForUser tmp_PauseforCursor,$grfName

    return 0
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
    String ctrlName

    DoWindow/K tmp_PauseforCursor // Kill self
End

```

And here is a routine that demonstrates the UserCursorAdjust code. To try this yourself, copy and paste all three routines into the procedure window of a new experiment and then run the Demo function.

```

Function Demo()
    Make/O jack;SetScale x,-5,5,jack
    jack= exp(-x^2)+gnoise(0.1)
    DoWindow Graph0
    if( V_Flag==0 )
        Display jack
        ShowInfo
    endif
    if (UserCursorAdjust("Graph0") != 0)
        return -1;
    endif
    CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
End

```

PauseForUser Advanced Cursor Example

Now for something a bit more complex. Here we modify the preceding example to include a Cancel button. For this, we need to return information about which button was pressed. Although we could do this by creating a single global variable in the root data folder, we use a slightly more complex technique using a temporary data folder. This technique is especially useful for more complex panels with multiple output variables because it limits any worry about name conflicts to the data folder itself. It also allows much easier clean up because we can kill the entire data folder and everything in it with just one operation.

```

Function UserCursorAdjust(grfName)
    String grfName

    DoWindow/F $grfName // Bring graph to front
    if (V_Flag == 0) // Verify that graph exists
        Abort "UserCursorAdjust: No such graph."
        return -1
    endif

    NewDataFolder/O root:tmp_PauseforCursorDF
    Variable/G root:tmp_PauseforCursorDF:canceled= 0

    NewPanel/K=2 /W=(139,341,382,450) as "Pause for Cursor"
    DoWindow/C tmp_PauseforCursor // Set to an unlikely name
    AutoPositionWindow/E/M=1/R=$grfName // Put panel near the graph

    DrawText 21,20,"Adjust the cursors and then"
    DrawText 21,40,"Click Continue."
    Button button0,pos={80,58},size={92,20},title="Continue"
    Button button0,proc=UserCursorAdjust_ContButtonProc
    Button button1,pos={80,80},size={92,20}
    Button button1,proc=UserCursorAdjust_CancelBProc,title="Cancel"

```

```
PauseForUser tmp_PauseforCursor,$grfName

NVAR gCaneled= root:tmp_PauseforCursorDF:canceled
Variable canceled= gCaneled // Copy from global to local
                             // before global is killed
KillDataFolder root:tmp_PauseforCursorDF

return canceled
End

Function UserCursorAdjust_ContButtonProc(ctrlName) : ButtonControl
String ctrlName

DoWindow/K tmp_PauseforCursor // Kill self
End

Function UserCursorAdjust_CancelBProc(ctrlName) : ButtonControl
String ctrlName

Variable/G root:tmp_PauseforCursorDF:canceled= 1
DoWindow/K tmp_PauseforCursor // Kill self
End
```

And now a demo that uses the new version:

```
Function Demo()
Make/O jack;SetScale x,-5,5,jack
jack= exp(-x^2)+gnoise(0.1)
DoWindow Graph0
if (V_Flag==0)
Display jack
ShowInfo
endif
Variable rval= UserCursorAdjust("Graph0")
if (rval == -1) // Graph name error?
return -1;
endif
if (rval == 1) // User canceled?
DoAlert 0,"Canceled"
return -1;
endif
CurveFit gauss,jack[pcsr(A),pcsr(B)] /D
End
```

PauseForUser Control Panel Example

The following is a very simple example of using a control panel as modal dialog. The panel was designed by first manually creating a data folder with a few variables and then creating a panel. When the panel was designed properly, it was closed to create a recreation macro. Lines from the macro were then used in the body of the function.

```
Function UserGetInputPanel_ContButton(ctrlName) : ButtonControl
String ctrlName

DoWindow/K tmp_GetInputPanel // kill self
End

// Call with these variables already created and initialized:
// root:tmp_PauseForUserDemo:numvar
// root:tmp_PauseForUserDemo:strvar
Function DoMyInputPanel()
NewPanel /W=(150,50,358,239)
DoWindow/C tmp_GetInputPanel // set to an unlikely name
DrawText 33,23,"Enter some data"
SetVariable setvar0,pos={27,49},size={126,17},limits={-Inf,Inf,1}
SetVariable setvar0,value= root:tmp_PauseForUserDemo:numvar
```

```

SetVariable setvar1,pos={24,77},size={131,17},limits={-Inf,Inf,1}
SetVariable setvar1,value= root:tmp_PauseForUserDemo:strvar
Button button0,pos={52,120},size={92,20}
Button button0,proc=UserGetInputPanel_ContButton,title="Continue"

PauseForUser tmp_GetInputPanel
End

Function Demo1()
  NewDataFolder/O root:tmp_PauseForUserDemo
  Variable/G root:tmp_PauseForUserDemo:numvar= 12
  String/G root:tmp_PauseForUserDemo:strvar= "hello"

  DoMyInputPanel()

  NVAR numvar= root:tmp_PauseForUserDemo:numvar
  SVAR strvar= root:tmp_PauseForUserDemo:strvar

  printf "You entered %g and %s\r",numvar,strvar

  KillDataFolder root:tmp_PauseForUserDemo
End

```

For comparison, here is the equivalent using the simple input dialog technique:

```

Function Demo2()
  Variable numvar= 12
  String strvar= "hello"
  Prompt numvar,"numvar:"
  Prompt strvar,"strvar:"
  DoPrompt "Enter some data",numvar,strvar
  printf "You entered %g and %s\r",numvar,strvar
End

```

Control Panels and Event-Driven Programming

The CalcDiagDialog function shown above creates a modal dialog. “Modal” means that the function retains complete control until the user clicks Cancel or Continue. The user can not activate another window or choose a menu item until the dialog is dismissed.

This section shows how to implement the same functionality using a control panel as a modeless dialog. “Modeless” means that the user can activate another window or choose a menu item at any time. The modeless window accepts input whenever the user wants to enter it but does not block the user from accessing other windows.

The control panel looks like this:

The code implementing this control panel is given below. Before we look at the code, here is some explanation of the thinking behind it.

The X Component and Y Component controls are SetVariable controls. Each SetVariable control must be attached to a global variable. To keep the global variables from cluttering the user’s space, we buried them in a data folder named root:Packages:DiagonalControlPanel.

We want the globals to be automatically created so the user does not need to worry about them, so we wrote a routine (DisplayDiagonalControlPanel) that makes sure that the variables and their containing data folders exist. The routine then creates the control panel or, if it already exists, just brings it to the front. We added a menu item to the Macros menu so the user can easily invoke DisplayDiagonalControlPanel.

Chapter IV-6 — Interacting with the User

We built the control panel manually using techniques explained in Chapter III-14, **Controls and Control Panels**. Then we closed it so Igor would create a display recreation macro which we named `DiagonalControlPanel`. We then manually tweaked the macro to attach the `SetVariable` controls to the desired globals and to set the panel's behavior when the user clicks the close button.

Here are the procedures.

```
// Add a menu item to display the control panel.
Menu "Macros"
    "Display Diagonal Control Panel", DisplayDiagonalControlPanel()
End

// This is the display recreation macro, created by Igor
// and then manually tweaked. The parts that were tweaked
// are shown in bold. NOTE: Some lines are wrapped to fit on the page.
Window DiagonalControlPanel() : Panel
    PauseUpdate; Silent 1    // building window...

    NewPanel/W=(162,95,375,198)/K=1 as "Compute Diagonal"

    SetVariable XSetVar,pos={22,11},size={150,15},title="X Component:"
    SetVariable XSetVar,limits={-Inf,Inf,1},value=
        root:Packages:DiagonalControlPanel:gXComponent

    SetVariable YSetVar,pos={22,36},size={150,15},title="Y Component:"
    SetVariable YSetVar,limits={-Inf,Inf,1},value=
        root:Packages:DiagonalControlPanel:gYComponent

    Button ComputeButton,pos={59,69},size={90,20},
        proc=ComputeDiagonalProc,title="Compute"
EndMacro

// This is the action procedure for the Compute button.
// We created it using the Button dialog.
Function ComputeDiagonalProc(ctrlName) : ButtonControl
    String ctrlName

    String dfSave = GetDataFolder(1)
    SetDataFolder root:Packages:DiagonalControlPanel

    NVAR gXComponent, gYComponent    // Access current data folder.
    Variable diagonal
    diagonal = sqrt(gXComponent^2 + gYComponent^2)
    Printf "Diagonal=%g\r", diagonal

    SetDataFolder dfSave
End

// This is the top level routine which makes sure that the globals
// and their enclosing data folders exist and then makes sure that
// the control panel is displayed.
Function DisplayDiagonalControlPanel()
    // If the panel is already created, just bring it to the front.
    DoWindow/F DiagonalControlPanel
    if (V_Flag != 0)
        return 0
    endif

    String dfSave = GetDataFolder(1)

    // Create a data folder in Packages to store globals.
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S root:Packages:DiagonalControlPanel

    // Create global variables used by the control panel.
    Variable xComponent = NumVarOrDefault(":gXComponent", 10)
```

```

Variable/G gXComponent = xComponent
Variable yComponent = NumVarOrDefault(":gYComponent", 20)
Variable/G gYComponent = yComponent

// Create the control panel.
Execute "DiagonalControlPanel()"

SetDataFolder dfSave
End

```

Although this example is very simple, it illustrates the process of creating a control panel that functions as a modeless dialog. There are many more examples of this in the Examples folder. See Chapter III-14, **Controls and Control Panels**, for more information on building control panels.

Detecting a User Abort

If you have written a user-function that takes a long time to execute, you may want to provide a way for the user to abort it. Your first instinct might be to create a control panel with a Stop button. This won't work because Igor does not look at controls while your user function is running. Instead, you must detect that the user is pressing Escape, as this example illustrates:

```

Function PressEscapeToAbort(phase, title, message)
    Variable phase    // 0: Display control panel with message.
                    // 1: Test if Escape key is pressed.
                    // 2: Close control panel.
    String title      // Title for control panel.
    String message    // Tells user what you are doing.

    if (phase == 0)   // Create panel
        DoWindow/F PressEscapePanel
        if (V_flag == 0)
            NewPanel/K=1 /W=(100,100,350,200)
            DoWindow/C PressEscapePanel
            DoWindow/T PressEscapePanel, title
        endif
        TitleBox Message,pos={7,8},size={69,20},title=message
        String abortStr = "Press escape to abort"
        TitleBox Press,pos={6,59},size={106,20},title=abortStr
        DoUpdate
    endif

    if (phase == 1)   // Test for Escape key
        Variable doAbort = 0
        if (GetKeyState(0) & 32)    // Is Escape key pressed now?
            doAbort = 1
        else
            if (strlen(message) != 0) // Want to change message?
                TitleBox Message,title=message
                DoUpdate
            endif
        endif
        return doAbort
    endif

    if (phase == 2)   // Kill panel
        DoWindow/K PressEscapePanel
    endif

    return 0
End

```

```
Function Demo()  
    // Create panel  
    PressEscapeToAbort(0, "Demonstration", "This is a demo")  
  
    Variable startTicks = ticks  
    Variable endTicks = startTicks + 10*60  
    Variable lastMessageUpdate = startTicks  
  
    do  
        String message  
        message = ""  
        if (ticks>=lastMessageUpdate+60) // Time to update message?  
            Variable remaining = (endTicks - ticks) / 60  
            sprintf message, "Time remaining: %.1f seconds", remaining  
            lastMessageUpdate = ticks  
        endif  
  
        if (PressEscapeToAbort(1, "", message))  
            Print "Test aborted by Escape key."  
            break  
        endif  
    while(ticks < endTicks)  
  
    PressEscapeToAbort(2, "", "") // Kill panel.  
End
```

Cursors as Input Device

You can use the cursors on a trace in a graph to identify the data to be processed.

The examples shown above using `PauseForUser` are modal - the user adjusts the cursors in the middle of procedure execution and can do nothing else. This technique is nonmodal — the user is expected to adjust the cursors before invoking the procedure.

This function does a straight-line curve fit through the data between cursor A (the round cursor) and cursor B (the square cursor). This example is written to handle both waveform and XY data.

```
Function FitLineBetweenCursors()  
    Variable isXY  
  
    // Make sure both cursors are on the same wave.  
    WAVE wA = CsrWaveRef(A)  
    WAVE wB = CsrWaveRef(B)  
    String dfA = GetWavesDataFolder(wA, 2)  
    String dfB = GetWavesDataFolder(wB, 2)  
    if (CmpStr(dfA, dfB) != 0)  
        Abort "Both cursors must be on the same wave."  
        return -1  
    endif  
  
    // Find the wave that the cursors are on.  
    WAVE yWave = CsrWaveRef(A)  
  
    // Decide if this is an XY pair.  
    WAVE xWave = CsrXWaveRef(A)  
    isXY = WaveExists(xWave)  
  
    if (isXY)  
        CurveFit line yWave(xcsr(A),xcsr(B)) /X=xWave /D  
    else  
        CurveFit line yWave(xcsr(A),xcsr(B)) /D  
    endif  
End
```

This technique is demonstrated in the **Fit Line Between Cursors** example experiment in the “Examples:Curve Fitting” folder.

Advanced programmers can set things up so that a hook function is called whenever the user adjusts the position of a cursor. For details, see **Cursors — Moving Cursor Calls Function** on page IV-220.

Marquee Menu as Input Device

A marquee is the dashed-line rectangle that you get when you click and drag diagonally in a graph or page layout. It is used for expanding and shrinking the range of axes and for specifying an area of a layout. You can use the marquee as an input device for your procedures. This is a relatively advanced technique.

This menu definition adds a user-defined item to the graph marquee menu:

```
Menu "GraphMarquee"  
  "Print Marquee Coordinates", PrintMarqueeCoords()  
End
```

To add an item to the layout marquee menu, use `LayoutMarquee` instead of `GraphMarquee`.

When the user chooses `Print Marquee Coordinates`, the following function runs. It prints the coordinates of the marquee in the history area. It assumes that the graph has left and bottom axes.

```
Function PrintMarqueeCoords()  
  String format  
  GetMarquee/K left, bottom  
  format = "flag: %g; left: %g; top: %g; right: %g; bottom: %g\r"  
  printf format, V_flag, V_left, V_top, V_right, V_bottom  
End
```

The ability to add items to the marquee menus through `GraphMarquee` and `LayoutMarquee` menu definitions was added in Igor Pro 5. Before that, the `GraphMarquee` and `LayoutMarquee` procedure subtype keywords were used. This technique is no longer recommended but is still supported.

The use of the marquee menu as an input device is demonstrated in the **Marquee Demo** and **Delete Points from Wave** example experiments.

Polygon as Input Device

This technique is similar to the marquee technique except that you can identify a nonrectangular area. It is implemented using **FindPointsInPoly** operation (see page V-157).

Overview

This chapter discusses programming techniques and issues that go beyond the basics of the Igor programming language and which all Igor programmers should understand. Techniques for advanced programmers are discussed in Chapter IV-10, **Advanced Programming**.

The Include Statement

The include statement is a “compiler directive” that you can put in your procedure file to automatically open another procedure file. A typical include statement looks like this:

```
#include <String Substitution>
```

This statement automatically opens the file String Substitution in the WaveMetrics Procedures folder. Once this statement has been compiled, you can call routines from that file. This is the recommended way to access procedure files that contain utility routines.

The # character at the beginning specifies that a compiler directive follows. Compiler directives must start at the far left edge of the procedure window with no leading tabs or spaces. Include statements can appear anywhere in the file but it is conventional to put them near the top.

It is possible to include a file which in turn includes other files that will automatically open.

Included files are opened when procedures are compiled. If you remove an include statement from a procedure file, the file will automatically close when you next compile.

There are four forms of the include statement specifying where files are located:

1. The named file is in the WaveMetrics Procedures folder and in any subfolders:

```
#include <fileName>
```

Example: #include <String Substitution>

2. The named file is in the User Procedures folder and in any subfolders:

```
#include "fileName"
```

Example: #include "Test Utility Procs"

3. The file is in the exact location specified:

```
#include "full file path"
```

Example: #include "Hard Disk:Desktop Folder:Test Utility Procs"

4. The file is located relative to the Igor Pro folder or the folder containing the procedure file that contains the #include statement:

```
#include ":partial file path"
```

Example: #include ":Spectroscopy Procedures:Voigt Procs"

Prior to Igor Pro 6, this form searched relative to the Igor Pro Folder only. Now, if no file is found relative to the Igor Pro Folder, it searches again, but this time relative to the procedure file containing the #include statement. With this method you can distribute a master procedure file that includes helper procedure files stored next to the master.

In Igor Pro 6.02 or later, if the procedure file containing the relative #include statement is the built-in procedure file or a packed procedure file, the search for the included file is relative to the experiment file.

The name of the file being included must end with the standard “.ipf” extension but the extension is not used in the include statement.

To make it easier to update Igor Pro, it is a good idea to avoid mixing your files with Igor files. Instead of putting your procedure files directly in the User Procedures folder, you can put them in your own folder, outside the Igor Pro folder. Then you put an alias (*Macintosh*) or shortcut (*Windows*) for your folder in the User Procedures folder. Igor will then search your folder when you use the second form to include a file.

Procedure File Version Information

If you create a procedure file to be used by other Igor users, it's a good idea to add version information to the file. You do this by putting a `#pragma version` statement in the procedure file. For example:

```
#pragma version = 1.10
```

This statement must appear with no indentation and must appear in the first 50 lines of the file. If Igor does not find the `#pragma version` statement and if Igor is running on Macintosh, it then looks for a `'vers',1` resource, which advanced programmers can add using the Apple-supplied ResEdit program. If Igor finds neither the `#pragma` statement nor the resource, it treats the file as version 1.00.

Igor looks for the version information when the user invokes the File Information dialog from the Procedure menu. If the file has version information, Igor displays the version next to the file name in the dialog.

Igor also looks for version information when it opens an included file. An include statement can require a certain version of the included file using the following syntax:

```
#include <Bivariate Histogram>, version>=1.03
```

If the required version of the procedure file is not available, Igor displays a warning to inform the user that the procedure file needs to be updated.

Turning the Included File's Menus Off

Normally an included procedure file's menus and menu items are displayed. However, if you are including a file merely to call one of its procedures, you may not want that file's menu items to appear. To suppress the file's menus and menu items, use:

```
#include <Decimation> menus=0
```

To use both the menus and version options, you must separate them with a comma:

```
#include <Decimation> menus=0, version>=1.1
```

Writing General-Purpose Procedures

Procedures can be placed on a scale ranging from general to specific. Usually, the high-level procedures of a program are specific to the task at hand and call on more general, lower-level procedures. The most general procedures are often called "utility" procedures.

You can achieve a high degree of productivity by building a library of utility procedures that you reuse in different programs. In Igor, you can think of the routines in an experiment's built-in Procedure window as a program. It can call utility routines which should be stored in a separate procedure file so that they are available to multiple experiments.

The files stored in the WaveMetrics Procedures folder contain general-purpose procedures on which your high-level procedures can build. Use the include statement (see **The Include Statement** on page IV-119) to access these and other utility files.

When you write utility routines, you should keep them as general as possible so that they can be reused as much as possible. Here are some guidelines.

- Avoid the use of global variables as inputs or outputs. Using globals hard-wires the routine to specific names which makes it difficult to use and limits its generality.
- If you use globals to store state information between invocations of a routine, package the globals in data folders.

WaveMetrics packages usually create data folders inside "root:Packages". We use the prefix "WM" for data folder names to avoid conflict with other packages. Follow this lead and should pick your own data folder names so as to minimize the chance of conflict with WaveMetrics packages or with others.

- Choose a clear and specific name for your utility routine.

By choosing a name that says precisely what your utility routine does, you minimize the likelihood of collision with the name of another procedure. You also increase the readability of your program.

- Make functions which are used only internally by your procedures static.

By making internal functions static (i.e., private), you minimize the likelihood of collision with the name of another procedure.

Programming with Liberal Names

Standard names in Igor may contain letters, numbers and the underscore character only. Starting with Igor Pro 3.0, it became possible to use wave names and data folder names that contain almost any character (see **Liberal Object Names** on page III-400). However, if you do use liberal names, some existing Igor procedures and extensions may break. Programmers will need to make changes to their procedures to ensure they will work with liberal names.

Whenever a liberal name is used in a command or expression, the name must be enclosed in single quotes. For example:

```
Make 'Wave 1', wave2, 'miles/hour'
'Wave 1' = wave2 + 'miles/hour'
```

Without the single quotes, Igor has no way to know where a particular name ends. This is a problem whenever Igor parses a command or statement. Igor parses commands at the following times:

- When it compiles a user-defined function.
- When it compiles the right-hand side of an assignment statement, including a formula (:= dependency expression).
- When it interprets a macro.
- When it interprets a command that you enter in the command line or via an Igor Text file.
- When it interprets a command you submit for execution via the Execute operation.
- When it interprets a command that an XOP submits for execution via the XOPCommand or XOPSilentCommand callback routines.

When you use an Igor dialog to generate a command, Igor automatically uses quotes where necessary.

Programmers need to be concerned about liberal names whenever they create a command and then execute it (via an Igor Text file, the Execute operation or the XOPCommand and XOPSilentCommand callback routines) or when creating a formula. In short, when you create something that Igor has to parse, names must be quoted if they are liberal. Names that are not liberal can be quoted or unquoted.

If you have a procedure that builds up a command in a string variable and then executes it via the Execute operation, you must use the PossiblyQuoteName function to provide the quotes if needed.

Here is a trivial example showing the old way of doing this along with the new, liberal-name aware way.

```
Function AddOneToWave(w)
    WAVE w

    String cmd
    String name = NameOfWave(w)

    // Here is the old way
    sprintf cmd, "%s += 1", name
    Execute cmd

    // Here is the new, liberal-name aware way
    sprintf cmd, "%s += 1", PossiblyQuoteName(name)
    Execute cmd
End
```

Imagine that you pass a wave named *wave 1* to this function. Using the old method, the Execute operation would see the following text:

```
wave 1 += 1
```

Chapter IV-7 — Programming Techniques

Igor will generate an error because it will try to find an operation, macro, function, wave or variable named *wave*.

Using the new method, the Execute operation would see the following text:

```
'wave 1' += 1
```

This works correctly because Igor sees 'wave 1' as a single name.

Depending on exactly what they do with their parameters, Igor procedures and extensions written before Igor Pro 3.0 or which have not been tested with liberal names may cause errors like this to occur. The safe route is to test all of the procedures and extensions that you rely on before routinely using liberal names.

When you pass a string expression containing a simple name to the \$ operator, the name must not be quoted because Igor does no parsing — the name is used as is. Examples:

```
String w = "wave 1"; Display $w                // Right
String w = "'wave 1'"; Display $w              // Wrong
String w = "wave 1"; Display $PossiblyQuoteName(w) // Wrong
```

Caution: When using the \$ operator to convert a string containing a liberal name, be aware that a full path name (like "root:folder1:waveName") *must* have any liberal names in single quotes (\$"root:folder #1:'wave #2'"). Just a wave name must not be quoted (\$"wave #2").

Some built-in string functions return a list of waves. WaveList is the most common example. If liberal wave names are used, you will have to be extra careful when using the list of names. For example, you can't just append the list to the name of an operation that takes a list of names and then execute the resulting string. Rather, you will have to extract each name in turn, possibly quote it and then append it to the operation.

For example, the following will work if all wave names are standard but not if any wave names are liberal:

```
Execute "Display " + WaveList("*, ", ", ", ")
```

Now you will need a string function that extracts out each name, possibly quotes it, and creates a new string using the new names separated by commas. The PossiblyQuoteList function in the WaveMetrics procedure file Strings as Lists does this. The preceding command becomes:

```
Execute "Display " + PossiblyQuoteList(WaveList("*, ", ", ", "), ", ")
```

To include the Strings as Lists file in your procedures, see **The Include Statement** on page IV-119.

Programming with Data Folders

For general information on data folders, including syntax for using data folders in command line operations, see Chapter II-8, **Data Folders**.

Data folders provide a powerful way for intermediate and advanced programmers to organize their data and to reduce clutter. However, using data folders introduces some complexity in Igor programming. The name of a variable or wave is no longer sufficient to uniquely identify it because the name alone does not indicate in which data folder it resides.

There are two main uses for data folders:

- To store globals used by procedures to keep track of their state.
- To store runs of data with identical structures.

Storing Procedure Globals

If you create packages of procedures, for example data acquisition, data analysis, or a specialized plot type, you typically need to store global variables, strings and waves to maintain the state of your package. You should keep all such items in a data folder that you create with a unique name to reduce clutter and avoid conflicts with other packages.

If your package is inherently global in nature, data acquisition for example, create your data folder within a data folder named Packages that you create (if necessary) in the root data folder. For example:

```
Function MyDAQInit()
    String savDF= GetDataFolder(1)    // Save current DF for restore.

    NewDataFolder/O/S root:Packages    // Make sure this exists.

    if( DataFolderExists("WMDDataAcq") ) // Already created WMDDataAcq?
        SetDataFolder WMDDataAcq      // Our stuff is in here.
        < do reinitialization if necessary >
    else
        NewDataFolder/S WMDDataAcq      // Our stuff goes in here.
        Variable/G avar                  // Create at runtime.
        < do other initialization if necessary >
    endif

    SetDataFolder savDF                  // Restore current DF.
End
```

On the other hand, if your package needs to create a group of variables and waves as a result of an operation on a single input wave, it makes sense to create your data folder in the one that holds the input wave (see the **GetWavesDataFolder** function on page V-198). Similarly, if you create a package that takes an entire data folder as input (via a string parameter containing the path to the data folder), does operations on what it finds inside and then needs to create a folder of output, it should create the output data folder in the one, or possibly at the same level as the one containing the input.

If your package creates and maintains windows, it should create a master data folder in root:Packages and then create individual folders within the master that correspond to each instance of a window. For example, a Smith Chart package would create a master data folder as root:Packages:SmithCharts: and then create individual folders inside the master with names that correspond to the individual graphs.

A package designed to operate on traces within graphs would go one step further and create a data folder for each trace that it has worked on, inside the data folder for the graph. This technique is illustrated by the Smooth Control Panel procedure file. For a demonstration, see Examples:Feature Demos:Smoothing Control Panel.pxp.

Storing Runs of Data

If you acquire data using a well-established experimental protocol, your data will have a well-defined structure. Each time you run your protocol, you produce a new data set with the same structure. Storing each data set in its own data folder avoids name conflicts between corresponding items of different data sets. It also simplifies the writing of procedures to analyze and compare data set.

To use a trivial example, your data might have a structure like this:

```
<Run of data>
    String: conditions
    Variable: temperature
    Wave: appliedVoltage
    Wave: luminosity
```

Having defined this structure, you could then write procedures to:

1. Load your data into a data folder
2. Create a graph showing the data from one run
3. Create a graph comparing the data from many runs

Writing these procedures is greatly simplified by the fact that the names of the items in a run are fixed. For example, step 2 could be written as:

```
Function GraphOneRun() // Graphs data run in the current data folder.
    SVAR conditions
    NVAR temperature
    WAVE appliedVoltage, luminosity
```

```
Display luminosity vs appliedVoltage

String text
sprintf text, "Temperature: %g.\rExperimental conditions: %s.",
    temperature, conditions
Textbox text
End
```

To create a graph, you would first set the current data folder to point to a run of data and then you would invoke the `GraphOneRun` function.

The Data Folder Tutorial experiment, in the Learning Aids:Tutorials folder, shows in detail how to accomplish the three steps listed above.

Setting and Restoring the Current Data Folder

There are many reasons why you might want to save and restore the current data folder. In this example, we have a function that does a curve fit to a wave passed in as a parameter. The `CurveFit` operation creates two waves, `W_coef` and `W_sigma`, in the current data folder. If you use the `/D` option, it also creates a destination wave in the current data folder. In this function, we make sure that the `W_coef`, `W_sigma` and destination waves are all created in the same data folder as the source wave.

```
Function DoLineFit(w)
    WAVE w

    String dfSav = GetDataFolder(1)
    SetDataFolder GetWavesDataFolder(w,1)
    CurveFit line w /D
    SetDataFolder dfSav
End
```

Many other operations create output waves in the current data folder. Depending on what your goal is, you may want to use the technique shown here to control where the output waves are created.

A function should always save and restore the current data folder unless it is designed explicitly to change the current data folder.

Determining a Function's Target Data Folder

There are three common methods for determining the data folder that a function works on or in:

1. Passing a wave in the target data folder as a parameter
2. Having the function work on the current data folder
3. Passing a string parameter that points to the target data folder

For functions that operate on a specific wave, method 1 is appropriate.

For functions that operation on a large number of variables within a single data folder, methods 2 or 3 are appropriate. In method 2, the calling routine sets the data folder of interest as the current data folder. In method 3, the called function does this, and restores the original current data folder before it returns.

Clearing a Data Folder

There are times when you might want to clear a data folder before running a procedure, to remove things left over from a preceding run. If the data folder contains no child data folders, you can achieve this with:

```
KillWaves/A/Z; KillVariables/A/Z
```

If the data folder does contain child data folders, you could use the `KillDataFolder` operation. This operation kills a data folder and its contents, including any child data folders. You could kill the main data folder and then recreate it. A problem with this is that, if the data folder or its children contain a wave that is in use, you will generate an error which will cause your function to abort.

Here is a handy function that kills the contents of a data folder and the contents of its children without killing any data folders and without attempting to kill any waves that may be in use.

```
Function ZapDataInFolderTree(path)
    String path

    String savDF= GetDataFolder(1)
    SetDataFolder path

    KillWaves/A/Z
    KillVariables/A/Z
    KillStrings/A/Z

    Variable i
    Variable numDataFolders = CountObjects(":", 4)
    for(i=0; i<numDataFolders; i+=1)
        String nextPath = GetIndexedObjName(":", 4, i)
        ZapDataInFolderTree(nextPath)
    endfor

    SetDataFolder savDF
End
```

Using Strings

This section explains some common ways in which Igor procedures use strings. The most common techniques use built-in functions such as StringFromList and FindListItem. In addition to the built-in functions, there are a number of handy Igor procedure files in the WaveMetrics Procedures:Utilities:String Utilities folder.

Using Strings as Lists

Procedures often need to deal with lists of items. Such lists are usually represented as semicolon-separated text strings. The StringFromList function is used to extract each item, often in a loop. For example:

```
Function Test()
    Make jack,sam,fred,sue
    String list = WaveList(":", ";", ",")
    Print list

    Variable numItems=ItemsInList(list), i
    for(i=0; i<numItems; i+=1)
        Print StringFromList(i,list)    // Print ith item
    endfor
End
```

Using Keyword-Value Packed Strings

A collection of disparate values is often stored in a list of keyword-value pairs. For example, the TraceInfo and AxisInfo functions return such a list. The information in these strings follows this form

```
KEYWORD:value;KEYWORD:value; ...
```

The **keyword** is always upper case and followed by a colon. Then comes the **value** and a semicolon. When parsing such a string, you should avoid reliance on the specific ordering of keywords — the order is likely to change in future releases of Igor.

Two functions will extract information from keyword-value strings. NumberByKey is used when the data is numeric, and StringByKey is used when the information is in the form of text.

Using Strings with Extractable Commands

The **AxisInfo** and **TraceInfo** readback functions provide much of their information in a form that resembles the commands that you use to make the settings in the first place. For example, to set an axis to log mode, you would execute something like this:

```
ModifyGraph log(left)=1
```

If we now look at the characters of the string returned by **AxisInfo** we see:

```
AXTYPE:left;CWAVE:jack; ... RECREATION:grid(x)=0;log(x)=1 ...
```

To use this information, we need to extract the value following “log(x)=” and then use it in a **ModifyGraph** command with the extracted value with the desired graph as the target. Here is a user function that sets the log mode of the bottom axis to the same value as the left axis:

```
Function CopyLogMode()
    String info,text
    Variable pos
    info=AxisInfo("", "left")
    pos= StrSearch(info,"RECREATION:",0)    // skip to start of "RECREATION:"
    pos += strlen("RECREATION:")           // skip "RECREATION:", too
                                           // get text after "log(x)="
    text= StringByKey("log(x)",info[pos,inf], "=", ";")

    String cmd = "ModifyGraph log(bottom)=" + text
    Execute cmd
End
```

Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the “subject”.

In the case of the **Grep** operation (see page V-204), the subject is each line of the input file, or for a text wave input, one or more columns of each row, considered one line or row at a time.

For the **GrepList** function (see page V-211) the subject is each string list item, considered one item at a time.

For the **GrepString** function (see page V-211) and the **SplitString** operation (see page V-528), the subject is the (only) input string.

The regular expression syntax is based on the PCRE — Perl-Compatible Regular Expression Library.

Igor syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. Igor’s implementation does not support the Unicode (UTF-8) section of PCRE. See **Regular Expressions References** on page IV-141.

Basic Regular Expressions

As a trivial example, the pattern “Fred” as specified here in a **Grep** command.

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

matches lines that contain the string “Fred” anywhere on the line.

Character matching is case-sensitive by default, similar to **strsearch**. Prepend the Perl 5 modifier `(?i)` to match upper and lower-case versions of “Fred”:

```
// Copy lines that contain "Fred", "fred", "FRED", "fRED", etc
Grep/P=myPath/E="( ?i)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do not match the regular expression, use the **Grep /E** flag with the optional *reverse* parameter set to 1 to reverse the sense of the match:

```
// Copy lines that do NOT contain "Fred", "fred", "fRED", etc
Grep/P=myPath/E={"(?i)fred",1} "afile.txt" as "NotFredFile.txt"
```

Note: Igor doesn't use the Perl or Unix opening and closing regular expression delimiters. They would have used `/Fred/` and `/(?i)fred/`.

Regular Expression Metacharacters

The power of regular expressions comes from the ability to include alternatives and repetitions in the pattern. These are encoded in the pattern by the use of “metacharacters”, which do not stand for themselves but instead are interpreted in some special way.

There are two different sets of metacharacters: those that are recognized anywhere in the pattern except within brackets, and those that are recognized in brackets. Outside brackets, the metacharacters are as follows:

<code>\</code>	General escape character with several uses
<code>^</code>	Assert start of string
<code>\$</code>	Assert end of string
<code>.</code>	Match any character except newline (by default)
<code>[</code>	Start character class definition
<code> </code>	Start of alternative branch
<code>(</code>	Start subpattern
<code>)</code>	End subpattern
<code>?</code>	Extends the meaning of <code>(</code> . Also 0 or 1 quantifier and quantifier minimizer
<code>*</code>	0 or more quantifier
<code>+</code>	1 or more quantifier. Also possessive quantifier
<code>{</code>	Start min/max quantifier

Part of a pattern that is in brackets is called a “character class”. In a character class the only metacharacters are:

<code>\</code>	General escape character
<code>^</code>	Negate the class, but only if the first character
<code>-</code>	Indicates character range
<code>[</code>	POSIX character class (only if followed by POSIX syntax)
<code>]</code>	Terminates the character class

The following sections describe the use of each of the metacharacters.

Backslash in Regular Expressions

The backslash character has several uses. Firstly, if it is followed by a nonalphanumeric character, it takes away any special meaning that character may have. This use of backslash as an escape character applies both inside and outside character classes.

For example, if you want to match a `*` character, you write `*` in the pattern. This escaping action applies whether or not the following character would otherwise be interpreted as a metacharacter, so it is always safe to precede a nonalphanumeric with backslash to specify that it stands for itself. In particular, if you want to match a backslash, you write `\\`.

Note: Because Igor also has special uses for backslash (see **Escape Characters in Strings** on page IV-13), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes sends one backslash to, say, the **Grep** command.

For example, to copy lines that contain a backslash followed by a `z` character, the Perl pattern would be `"\\z"`, but the equivalent Grep expression would be `/E="\\\\z"`.

Chapter IV-7 — Programming Techniques

This difference is important enough that the PCRE and Igor Patterns (using Grep /E syntax) are both shown below when they differ.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between `\Q` and `\E`. This is different from Perl in that `$` and `@` are handled as literals in `\Q...\E` sequences in PCRE, whereas in Perl, `$` and `@` cause variable interpolation. Note the following examples:

Igor Pattern	PCRE Pattern	PCRE Matches	Perl Matches
/E="\Qabc\$xyz\E	"\Qabc\$xyz\E	abc\$xyz	abc followed by the contents of \$xyz
/E="\Qabc\\\$xyz\E	"\Qabc\\\$xyz\E	abc\\\$xyz	abc\\\$xyz
/E="\Qabc\E\\\$\\Qxyz\E	"\Qabc\E\\\$\\Qxyz\E	abc\$xyz	abc\$xyz

The `\Q...\E` sequence is recognized both inside and outside character classes.

Backslash and Nonprinting Characters

A second use of backslash provides a way of encoding nonprinting characters in patterns in a visible manner. There is no restriction on the appearance of nonprinting characters, apart from the binary zero that terminates a pattern, but when a pattern is being prepared by text editing, it is usually easier to use one of the following escape sequences than the binary character it represents:

Igor Pattern	PCRE Pattern	Character Matched
/E="\a	"\a	Alarm, that is, the BEL character (hex 07)
/E="\cx	"\cx	"Control-x", where x is any character
/E="\e	"\e	Escape (hex 1B)
/E="\f	"\f	Formfeed (hex 0C)
/E="\n	"\n	Newline (hex 0A)
/E="\r	"\r	Carriage return (hex 0D)
/E="\t	"\t	Tab (hex 09)
/E="\ddd	"\ddd	Character with octal code ddd, or backreference
/E="\xhh	"\xhh	Character with hex code hh

The precise effect of `\cx` is if `x` is a lower case letter, it is converted to upper case. Then bit 6 of the character (hex 40) is inverted. Thus `\cz` becomes hex 1A, but `\c{` becomes hex 3B, while `\c;` becomes hex 7B.

After `\x`, from zero to two hexadecimal digits are read (letters can be in upper or lower case). If characters other than hexadecimal digits appear between `\x{` and `}`, or if there is no terminating `}`, this form of escape is not recognized. Instead, the initial `\x` will be interpreted as a basic hexadecimal escape, with no following digits, giving a character whose value is zero.

After `\0` up to two further octal digits are read. In both cases, if there are fewer than two digits, just those that are present are used. Thus the sequence `\0\x\07` specifies two binary zeros followed by a BEL character (code value 7). Make sure you supply two digits after the initial zero if the pattern character that follows is itself an octal digit.

The handling of a backslash followed by a digit other than 0 is complicated. Outside a character class, PCRE reads it and any following digits as a decimal number. If the number is less than 10, or if there have been at least that many previous capturing left parentheses in the expression, the entire sequence is taken as a back reference. A description of how this works is given later, following the discussion of parenthesized subpatterns.

Inside a character class, or if the decimal number is greater than 9 and there have not been that many capturing subpatterns, PCRE rereads up to three octal digits following the backslash, and generates a single byte from the least significant 8 bits of the value. Any subsequent digits stand for themselves. For example:

Igor Pattern	PCRE Pattern	Character(s) Matched
/E="\040	"\040	Another way of writing a space
/E="\40	"\40	A space, provided there are fewer than 40 previous capturing subpatterns
/E="\7	"\7	Always a back reference
/E="\11	"\11	Might be a back reference, or another way of writing a tab
/E="\011	"\011	Always a tab
/E="\0113	"\0113	A tab followed by the character "3"
/E="\113	"\113	Might be a back reference, otherwise the character with octal code 113
/E="\377	"\377	Might be a back reference, otherwise the byte consisting entirely of 1 bits
/E="\81	"\81	Either a back reference or a binary zero followed by the two characters "8" and "1"

Note that octal values of 100 or greater must not be introduced by a leading zero, because no more than three octal digits are ever read.

All the sequences that define a single byte value can be used both inside and outside character classes. In addition, inside a character class, the sequence `\b` is interpreted as the backspace character (hex 08), and the sequence `\X` is interpreted as the character X. Outside a character class, these sequences have different meanings (see **Backslash and Nonprinting Characters** on page IV-128).

Backslash and Generic Character Types

The third use of backslash is for specifying generic character types. The following are always recognized:

Igor Pattern	PCRE Pattern	Character(s) Matched
/E="\d	"\d	Any decimal digit
/E="\D	"\D	Any character that is not a decimal digit
/E="\s	"\s	Any whitespace character
/E="\S	"\S	Any character that is not a whitespace character
/E="\w	"\w	Any "word" character
/E="\W	"\W	Any "nonword" character

Each pair of escape sequences partitions the complete set of characters into two disjoint sets. Any given character matches one, and only one, of each pair.

These character type sequences can appear both inside and outside character classes. They each match one character of the appropriate type. If the current matching point is at the end of the subject string, all of them fail, since there is no character to match.

For compatibility with Perl, `\s` does not match the VT character (code 11). This makes it different from the POSIX "space" class. The `\s` characters are HT (9), LF (10), FF (12), CR (13), and space (32).

A "word" character is an underscore or any character less than 256 that is a letter or digit.

Backslash and Simple Assertions

The fourth use of backslash is for certain simple assertions. An assertion specifies a condition that has to be met at a particular point in a match, without consuming any characters from the subject string. The use of subpatterns for more complicated assertions is described in **Assertions** on page IV-137. The backslashed assertions are:

Igor Pattern	PCRE Pattern	Character(s) Matched
/E="\\b	"\b	At a word boundary
/E="\\B	"\B	When not at a word boundary
/E="\\A	"\A	At start of subject
/E="\\Z	"\Z	At end of subject or before newline at end
/E="\\z	"\z	At end of subject
/E="\\G	"\G	At first matching position in subject

These assertions may not appear in character classes (but note that `\b` has a different meaning, namely the backspace character, inside a character class).

A word boundary is a position in the subject string where the current character and the previous character do not both match `\w` or `\W` (i.e. one matches `\w` and the other matches `\W`), or the start or end of the string if the first or last character matches `\w`, respectively.

While PCRE defines additional simple assertions (`\A`, `\Z`, `\z` and `\G`), they are not any more useful to Igor's regular expression commands than the `^` and `$` characters.

Circumflex and Dollar

Outside a character class, in the default matching mode, the circumflex character `^` is an assertion that is true only if the current matching point is at the start of the subject string. Inside a character class, circumflex has an entirely different meaning (see **Character Classes and Brackets** on page IV-130).

Circumflex need not be the first character of the pattern if a number of alternatives are involved, but it should be the first thing in each alternative in which it appears if the pattern is ever to match that branch. If all possible alternatives start with a circumflex, that is, if the pattern is constrained to match only at the start of the subject, it is said to be an "anchored" pattern. (There are also other constructs that can cause a pattern to be anchored.)

A dollar character `$` is an assertion that is true only if the current matching point is at the end of the subject string, or immediately before a newline character that is the last character in the string (by default). Dollar need not be the last character of the pattern if a number of alternatives are involved, but it should be the last item in any branch in which it appears. Dollar has no special meaning in a character class.

Dot, Period, or Full Stop

Outside a character class, a dot in the pattern matches any one character in the subject, including a nonprinting character, but not (by default) newline. Dot has no special meaning in a character class.

Character Classes and Brackets

An opening bracket introduces a character class, terminated by a closing bracket. A closing bracket on its own is not special. If a closing bracket is required as a member of the class, it should be the first data character in the class (after an initial circumflex, if present) or escaped with a backslash.

A character class matches a single character in the subject. A matched character must be in the set of characters defined by the class, unless the first character in the class definition is a circumflex, in which case the subject character must not be in the set defined by the class. If a circumflex is actually required as a member of the class, ensure it is not the first character, or escape it with a backslash.

For example, the character class `[aeiou]` matches any lower case vowel, whereas `[^aeiou]` matches any character that is not a lower case vowel. Note that a circumflex is just a convenient notation for specifying the characters that are in the class by enumerating those that are not. A class that starts with a circumflex is not an assertion: it still consumes a character from the subject string, and therefore it fails if the current pointer is at the end of the string.

When caseless matching `(?i)` is set, any letters in a class represent both their upper case and lower case versions, so for example, the caseless pattern `(?i)[aeiou]` matches *A* as well as *a*, and the caseless pattern `(?i)[^aeiou]` does not match *A*, whereas a careful version would.

The minus (hyphen) character can be used to specify a range of characters in a character class. For example, `[d-m]` matches any letter between *d* and *m*, inclusive. If a minus character is required in a class, it must be escaped with a backslash or appear in a position where it cannot be interpreted as indicating a range, typically as the first or last character in the class.

It is not possible to have the literal character `]` as the end character of a range. A pattern such as `[W-]46]` is interpreted as a class of two characters (*W* and `-`) followed by a literal string `"46]"`, so it would match `"W46]"` or `"-46]"`. However, if the `]` is escaped with a backslash it is interpreted as the end of range, so that `[W-\]46]` is interpreted as a class containing a range followed by two other characters. The octal or hexadecimal representation of `]` can also be used to end a range. The corresponding **Grep** command would begin with

```
Grep/E="[W-\]46]"...
```

Ranges operate in the collating sequence of character values. They can also be used for characters specified numerically, for example `[\000-\037]`.

The character types `\d`, `\D`, `\p`, `\P`, `\s`, `\S`, `\w`, and `\W` may also appear in a character class, and add the characters that they match to the class. For example, `[\dABCDEF]` matches any hexadecimal digit. A circumflex can conveniently be used with the upper case character types to specify a more restricted set of characters than the matching lower case type. For example, the class `[\^W_]` matches any letter or digit, but not underscore. The corresponding **Grep** command would begin with

```
Grep/E="[\^\\W_]"...
```

The only metacharacters that are recognized in character classes are backslash, hyphen (only where it can be interpreted as specifying a range), circumflex (only at the start), opening bracket (only when it can be interpreted as introducing a POSIX class name — see **POSIX Character Classes** on page IV-131), and the terminating closing bracket. However, escaping other nonalphanumeric characters does no harm.

POSIX Character Classes

Perl supports the POSIX notation for character classes. This uses names enclosed by `[:` and `:]` within the enclosing brackets. PCRE also supports this notation. For example,

```
[01[:alpha:]]%
```

matches `"0"`, `"1"`, any alphabetic character, or `"%"`. The supported class names are

<code>alnum</code>	Letters and digits
<code>alpha</code>	Letters
<code>ascii</code>	Character codes 0 - 127
<code>blank</code>	Space or tab only
<code>cntrl</code>	Control characters
<code>digit</code>	Decimal digits (same as <code>\d</code>)
<code>graph</code>	Printing characters, excluding space
<code>lower</code>	Lower case letters
<code>print</code>	Printing characters, including space
<code>punct</code>	Printing characters, excluding letters and digits

Chapter IV-7 — Programming Techniques

<code>space</code>	White space (not quite the same as <code>\s</code>)
<code>upper</code>	Upper case letters
<code>word</code>	“Word” characters (same as <code>\w</code>)
<code>xdigit</code>	Hexadecimal digits

The “space” characters are `HT` (9), `LF` (10), `VT` (11), `FF` (12), `CR` (13), and `space` (32). Notice that this list includes the `VT` character (code 11). This makes “space” different from `\s`, which does not include `VT` (for Perl compatibility).

The class name `word` is a Perl extension, and `blank` is a GNU extension from Perl 5.8. Another Perl extension is negation that is indicated by a `^` character after the colon. For example,

```
[12[:^digit:]]
```

matches “1”, “2”, or any nondigit. PCRE (and Perl) also recognize the POSIX syntax `[.ch.]` and `[=ch=]` where “ch” is a “collating element”, but these are not supported, and an error is given if they are encountered.

Vertical Bar

Vertical bar characters are used to separate alternative patterns. For example, the pattern

```
gilbert|sullivan
```

matches either “gilbert” or “sullivan”. Any number of alternative patterns may be specified, and an empty alternative is permitted (matching the empty string). The matching process tries each alternative in turn, from left to right, and the first one that succeeds is used. If the alternatives are within a subpattern (defined in **Subpatterns** on page IV-133), “succeeds” means matching the rest of the main pattern as well as the alternative in the subpattern.

Match Option Settings

Character matching options can be changed from within the pattern by a sequence of Perl option letters enclosed between (`?` and `)`. The option letters are

<code>i</code>	<code>PCRE_CASELESS</code>
<code>u</code>	<code>PCRE_UNGREEDY</code>

For example, `(?i)` sets caseless matching. It is also possible to unset these options by preceding the letter with a hyphen, and a combined setting and unsetting such as `(?i-U)`, which sets `PCRE_CASELESS` while unsetting `PCRE_UNGREEDY`. If a letter appears both before and after the hyphen, the option is unset.

When an option change occurs at top level (that is, not inside subpattern parentheses), the change applies to the remainder of the pattern that follows. If the change is placed right at the start of a pattern, PCRE extracts it into the global options.

An option change within a subpattern affects only that part of the current pattern that follows it, so

```
(a(?i)b)c
```

matches `abc` and `aBc` and no other strings (assuming `PCRE_CASELESS` is not used). By this means, options can be made to have different settings in different parts of the pattern. Any changes made in one alternative do carry on into subsequent branches within the same subpattern. For example,

```
(a(?i)b|c)
```

matches “ab”, “aB”, “c”, and “C”, even though when matching “C” the first branch is abandoned before the option setting. This is because the effects of option settings happen at compile time. There would be some very weird behavior otherwise.

The other PCRE-specific options (`m`, `s`, `x`, and `X`) are not useful with Igor’s regular expression commands.

Subpatterns

Subpatterns are delimited by parentheses, which can be nested. Turning part of a pattern into a subpattern does two things:

1. It localizes a set of alternatives. For example, the pattern `cat(aract|erpillar|)` matches one of the words “cat”, “cataract”, or “caterpillar”. Without the parentheses, it would match “cataract”, “erpillar” or the empty string.
2. It sets up the subpattern as a capturing subpattern. (This applies only to **SplitString**). This means that, when the whole pattern matches, that portion of the subject string that matched the subpattern is passed back to the calling routine. Opening parentheses are counted from left to right (starting from 1) to obtain numbers for the capturing subpatterns.

For example, if the string “the red king” is matched against the pattern

```
the ((red|white) (king|queen))
```

the captured substrings are “red king”, “red”, and “king”, and are numbered 1, 2, and 3, respectively. These are the store in the **SplitString**’s `TW_SubStrings` output wave.

The fact that plain parentheses fulfill two functions is not always helpful. There are often times when a grouping subpattern is required without a capturing requirement. If an opening parenthesis is followed by a question mark and a colon, the subpattern does not do any capturing, and is not counted when computing the number of any subsequent capturing subpatterns. For example, if the string “the white queen” is matched against the pattern

```
the ((?:red|white) (king|queen))
```

the captured substrings are “white queen” and “queen”, and are numbered 1 and 2. The maximum number of capturing subpatterns is 65535, and the maximum depth of nesting of all subpatterns, both capturing and noncapturing, is 200.

As a convenient shorthand, if any option settings are required at the start of a noncapturing subpattern, the option letters may appear between the `?` and the `:`. Thus the two patterns

```
(?i:saturday|sunday)
(?:(?i)saturday|sunday)
```

match exactly the same set of strings. Because alternative branches are tried from left to right, and options are not reset until the end of the subpattern is reached, an option setting in one branch does affect subsequent branches, so the above patterns match “SUNDAY” as well as “Saturday”.

Named Subpatterns

Identifying capturing parentheses by number is simple, but it can be very hard to keep track of the numbers in complicated regular expressions. Furthermore, if an expression is modified, the numbers may change. To help with this difficulty, PCRE supports the naming of subpatterns, something that Perl does not provide. The Python syntax (`?P<name>...`) is used. Names consist of alphanumeric characters and underscores, and must be unique within a pattern.

Named capturing parentheses are still allocated numbers as well as names.

Repetition

Repetition is specified by quantifiers, which can follow any of the following items:

- A literal data character
- The `.` metacharacter
- The `\C` escape sequence
- An escape such as `\d` that matches a single character
- A character class
- A back reference (see **Back References** on page IV-136)

Chapter IV-7 — Programming Techniques

- A parenthesized subpattern (unless it is an assertion)

The general repetition quantifier specifies a minimum and maximum number of permitted matches, by giving the two numbers in braces, separated by a comma. The numbers must be less than 65536, and the first must be less than or equal to the second. For example:

`z{2,4}`

matches “zz”, “zzz”, or “zzzz”. A closing brace on its own is not a special character. If the second number is omitted, but the comma is present, there is no upper limit; if the second number and the comma are both omitted, the quantifier specifies an exact number of required matches. Thus

`[aeiou]{3,}`

matches at least 3 successive vowels, but may match many more, while

`\d{8}`

matches exactly 8 digits. A left brace that appears in a position where a quantifier is not allowed, or one that does not match the syntax of a quantifier, is taken as a literal character. For example, `{,6}` is not a quantifier, but a literal string of four characters.

The quantifier `{0}` is permitted, causing the expression to behave as if the previous item and the quantifier were not present.

For convenience (and historical compatibility) the three most common quantifiers have single-character abbreviations:

<code>*</code>	Equivalent to <code>{0,}</code>
<code>+</code>	Equivalent to <code>{1,}</code>
<code>?</code>	Equivalent to <code>{0,1}</code>

It is possible to construct infinite loops by following a subpattern that can match no characters with a quantifier that has no upper limit, for example:

`(a?)*`

Earlier versions of Perl and PCRE used to give an error at compile time for such patterns. However, because there are cases where this can be useful, such patterns are now accepted, but if any repetition of the subpattern does in fact match no characters, the loop is forcibly broken.

By default, the quantifiers are “greedy”, that is, they match as much as possible (up to the maximum number of permitted times), without causing the rest of the pattern to fail. The classic example of where this gives problems is in trying to match comments in C programs. These appear between `/*` and `*/` and within the comment, individual `*` and `/` characters may appear. An attempt to match C comments by applying the pattern

`/*.*/` or `Grep/E="/*.*/"`

to the string

`/* first comment */ not comment /* second comment */`

fails, because it matches the entire string owing to the greediness of the `.*` item.

However, if a quantifier is followed by a question mark, it ceases to be greedy, and instead matches the minimum number of times possible, so the pattern

`/*.?*/` or `Grep/E="/*.?*/"`

does the right thing with the C comments. The meaning of the various quantifiers is not otherwise changed, just the preferred number of matches. Do not confuse this use of question mark with its use as a quantifier in its own right. Because it has two uses, it can sometimes appear doubled, as in

`\d??\d` or `Grep/E="\d??\d"`

which matches one digit by preference, but can match two if that is the only way the rest of the pattern matches.

If the PCRE_UNGREEDY option (?U) is set, the quantifiers are not greedy by default, but individual ones can be made greedy by following them with a question mark. In other words, it inverts the default behavior.

When a parenthesized subpattern is quantified with a minimum repeat count that is greater than 1 or with a limited maximum, more memory is required for the compiled pattern, in proportion to the size of the minimum or maximum.

When a capturing subpattern is repeated, the value captured is the substring that matched the final iteration. For example, after

```
(tweedle[dume]{3}\s*)+ or Grep/E="(tweedle[dume]{3}\s*)+"
```

has matched "tweedledum tweedledee" the value of the captured substring is "tweedledee". However, if there are nested capturing subpatterns, the corresponding captured values may have been set in previous iterations. For example, after

```
/(a|(b))+/
```

matches "aba" the value of the second captured substring is "b".

Atomic Grouping and Possessive Quantifiers

With both maximizing and minimizing repetition, failure of what follows normally reevaluates the repeated item to see if a different number of repeats allows the rest of the pattern to match. Sometimes it is useful to prevent this, either to change the nature of the match, or to cause it fail earlier than it otherwise might, when the author of the pattern knows there is no point in carrying on.

Consider, for example, the pattern `\d+foo` when applied to the subject line

```
123456bar
```

After matching all 6 digits and then failing to match "foo", the normal action of the matcher is to try again with only 5 digits matching the `\d+` item, and then with 4, and so on, before ultimately failing. "Atomic grouping" provides the means for specifying that once a subpattern has matched, it is not to be reevaluated in this way.

If we use atomic grouping for the previous example, the matcher would give up immediately on failing to match "foo" the first time. The notation is a kind of special parenthesis, starting with (?> as in this example:

```
(?>\d+)foo or Grep/E="( ?>\d+)foo"
```

This kind of parenthesis "locks up" the part of the pattern it contains once it has matched, and a failure further into the pattern is prevented from backtracking into it. Backtracking past it to previous items, however, works as normal.

An alternative description is that a subpattern of this type matches the string of characters that an identical standalone pattern would match, if anchored at the current point in the subject string.

Atomic grouping subpatterns are not capturing subpatterns. Simple cases such as the above example can be thought of as a maximizing repeat that must swallow everything it can. So, while both `\d+` and `\d+?` are prepared to adjust the number of digits they match in order to make the rest of the pattern match, `(?>\d+)` can only match an entire sequence of digits.

Atomic groups in general can of course contain arbitrarily complicated subpatterns, and can be nested. However, when the subpattern for an atomic group is just a single repeated item, as in the example above, a simpler notation, called a "possessive quantifier" can be used. This consists of an additional + character following a quantifier. Using this notation, the previous example can be rewritten as

```
\d++foo or Grep/E="\d++foo"
```

Possessive quantifiers are always greedy; the setting of the PCRE_UNGREEDY option is ignored. They are a convenient notation for the simpler forms of atomic group. However, there is no difference in the meaning or processing of a possessive quantifier and the equivalent atomic group.

The possessive quantifier syntax is an extension to the Perl syntax. It originates in Sun's Java package.

When a pattern contains an unlimited repeat inside a subpattern that can itself be repeated an unlimited number of times, the use of an atomic group is the only way to avoid some failing matches taking a very long time indeed. The pattern

```
(\D+|<\d+>)*[!?] or Grep/E="(\D+|<\d+>)*[!]"
```

matches an unlimited number of substrings that either consist of nondigits, or digits enclosed in <>, followed by either ! or ?. When it matches, it runs quickly. However, if it is applied to

```
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

it takes a long time before reporting failure. This is because the string can be divided between the internal \D+ repeat and the external * repeat in a large number of ways, and all have to be tried. (The example uses [!?] rather than a single character at the end, because both PCRE and Perl have an optimization that allows for fast failure when a single character is used. They remember the last single character that is required for a match, and fail early if it is not present in the string.) If the pattern is changed so that it uses an atomic group, like this:

```
((?>\D+)|<\d+>)*[!?] or Grep/E="((?>\D+)|<\d+>)*[!]"
```

sequences of nondigits cannot be broken, and failure happens quickly.

Back References

Outside a character class, a backslash followed by a digit greater than 0 (and possibly further digits) is a back reference to a capturing subpattern earlier (that is, to its left) in the pattern, provided there have been that many previous capturing left parentheses.

However, if the decimal number following the backslash is less than 10, it is always taken as a back reference, and causes an error only if there are not that many capturing left parentheses in the entire pattern. In other words, the parentheses that are referenced need not be to the left of the reference for numbers less than 10. See **Backslash and Nonprinting Characters** on page IV-128 for further details of the handling of digits following a backslash.

A back reference matches whatever actually matched the capturing subpattern in the current subject string, rather than anything matching the subpattern itself (see **Subpatterns as Subroutines** on page IV-141 for a way of doing that). So the pattern

```
(sens|respons)e and \libility or /E="(sens|respons)e and \\libility"
```

matches “sense and sensibility” and “response and responsibility”, but not “sense and responsibility”. If careful matching is in force at the time of the back reference, the case of letters is relevant. For example,

```
((?i)rah)\s+\1 or Grep/E="((?i)rah)\\s+\\1"
```

matches “rah rah” and “RAH RAH”, but not “RAH rah”, even though the original capturing subpattern is matched caselessly.

Back references to named subpatterns use the Python syntax (?P=name). We could rewrite the above example as follows:

```
(?<p1>(?(i)rah)\s+(?P=p1) or Grep/E="(?(p1)>(?(i)rah)\\s+(?P=p1)"
```

There may be more than one back reference to the same subpattern. If a subpattern has not actually been used in a particular match, any back references to it always fail. For example, the pattern

```
(a|(bc))\2
```

always fails if it starts to match “a” rather than “bc”. Because there may be many capturing parentheses in a pattern, all digits following the backslash are taken as part of a potential back reference number. If the pattern continues with a digit character, some delimiter must be used to terminate the back reference. An empty comment (see **Regular Expression Comments** on page IV-139) can be used.

A back reference that occurs inside the parentheses to which it refers fails when the subpattern is first used, so, for example, `(a\1)` never matches. However, such references can be useful inside repeated subpatterns. For example, the pattern

```
(a|b\1)+      or      Grep/E="(a|b\1)+"
```

matches any number of *a*'s and also "aba", "ababbaa" etc. At each iteration of the subpattern, the back reference matches the character string corresponding to the previous iteration. In order for this to work, the pattern must be such that the first iteration does not need to match the back reference. This can be done using alternation, as in the example above, or by a quantifier with a minimum of zero.

Assertions

An assertion is a test on the characters following or preceding the current matching point that does not actually consume any characters. The simple assertions coded as `\b`, `\B`, `^` and `$` are described in **Backslash and Simple Assertions** on page IV-130.

More complicated assertions are coded as subpatterns. There are two kinds: those that look ahead of the current position in the subject string, and those that look behind it. An assertion subpattern is matched in the normal way, except that it does not cause the current matching position to be changed.

Assertion subpatterns are not capturing subpatterns, and may not be repeated, because it makes no sense to assert the same thing several times. If any kind of assertion contains capturing subpatterns within it, these are counted for the purposes of numbering the capturing subpatterns in the whole pattern. However, substring capturing is carried out only for positive assertions, because it does not make sense for negative assertions.

Lookahead Assertions

Lookahead assertions start with `(?=` for positive assertions and `(?!` for negative assertions. For example,

```
\w+(?=;)      or      Grep/E="\w+(?=;)"
```

matches a word followed by a semicolon, but does not include the semicolon in the match, and

```
foo(?!bar)
```

matches any occurrence of "foo" that is not followed by "bar". Note that the apparently similar pattern

```
(?!foo)bar
```

does not find an occurrence of "bar" that is preceded by something other than "foo"; it finds any occurrence of "bar" whatsoever, because the assertion `(?!foo)` is always true when the next three characters are "bar". A lookbehind assertion is needed to achieve the other effect.

If you want to force a matching failure at some point in a pattern, the most convenient way to do it is with `(?!)` because an empty string always matches, so an assertion that requires there not to be an empty string must always fail.

Lookbehind Assertions

Lookbehind assertions start with `(?<=` for positive assertions and `(?<!` for negative assertions. For example,

```
(?<!foo)bar
```

does find an occurrence of "bar" that is not preceded by "foo". The contents of a lookbehind assertion are restricted such that all the strings it matches must have a fixed length. However, if there are several alternatives, they do not all have to have the same fixed length. Thus

```
(?<=bullock|donkey)
```

is permitted, but

```
(?<!dogs?|cats?)
```

causes an error at compile time. Branches that match different length strings are permitted only at the top level of a lookbehind assertion. This is an extension compared with Perl (at least for 5.8), which requires all branches to match the same length of string. An assertion such as

```
(?<=ab(c|de))
```

is not permitted, because its single top-level branch can match two different lengths, but it is acceptable if rewritten to use two top-level branches:

```
(?<=abc|abde)
```

The implementation of lookbehind assertions is, for each alternative, to temporarily move the current position back by the fixed width and then try to match. If there are insufficient characters before the current position, the match is deemed to fail.

Atomic groups can be used in conjunction with lookbehind assertions to specify efficient matching at the end of the subject string. Consider a simple pattern such as

```
abcd$
```

when applied to a long string that does not match. Because matching proceeds from left to right, PCRE will look for each *a* in the subject and then see if what follows matches the rest of the pattern. If the pattern is specified as

```
^.*abcd$
```

the initial `.*` matches the entire string at first, but when this fails (because there is no following *a*), it backtracks to match all but the last character, then all but the last two characters, and so on. Once again the search for *a* covers the entire string, from right to left, so we are no better off. However, if the pattern is written as

```
^(?>.*)(?<=abcd)
```

or, equivalently, using the possessive quantifier syntax,

```
^.*+(?<=abcd)
```

there can be no backtracking for the `.*` item; it can match only the entire string. The subsequent lookbehind assertion does a single test on the last four characters. If it fails, the match fails immediately. For long strings, this approach makes a significant difference to the processing time.

Using Multiple Assertions

Several assertions (of any sort) may occur in succession. For example,

```
(?<=\d{3})(?!999)foo or Grep/E="( ?<=\d{3})(?!999)foo"
```

matches “foo” preceded by three digits that are not “999”. Notice that each of the assertions is applied independently at the same point in the subject string. First there is a check that the previous three characters are all digits, and then there is a check that the same three characters are not “999”. This pattern does not match “foo” preceded by six characters, the first of which are digits and the last three of which are not “999”. For example, it doesn’t match “123abcfoo”. A pattern to do that is

```
(?<=\d{3}...)(?!999)foo or Grep/E="( ?<=\d{3}...)(?!999)foo"
```

This time the first assertion looks at the preceding six characters, checking that the first three are digits, and then the second assertion checks that the preceding three characters are not “999”.

Assertions can be nested in any combination. For example,

```
(?<=(?!foo)bar)baz
```

matches an occurrence of “baz” that is preceded by “bar” which in turn is not preceded by “foo”, while

```
(?<=\d{3}(?!999)... )foo or Grep/E="( ?<=\d{3}(?!999)... )foo"
```

is another pattern that matches “foo” preceded by three digits and any three characters that are not “999”.

Conditional Subpatterns

It is possible to cause the matching process to obey a subpattern conditionally or to choose between two alternative subpatterns, depending on the result of an assertion, or whether a previous capturing subpattern matched or not. The two possible forms of conditional subpattern are

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

If the condition is satisfied, the yes-pattern is used; otherwise the no-pattern (if present) is used. If there are more than two alternatives in the subpattern, a compile-time error occurs.

There are three kinds of condition. If the text between the parentheses consists of a sequence of digits, the condition is satisfied if the capturing subpattern of that number has previously matched. The number must be greater than zero. Consider the following pattern, which contains nonsignificant white space to make it more readable and to divide it into three parts for ease of discussion:

```
( \ ( )?    [ ^ ( ) ]+    (?(1) \ ) )
```

The first part matches an optional opening parenthesis, and if that character is present, sets it as the first captured substring. The second part matches one or more characters that are not parentheses. The third part is a conditional subpattern that tests whether the first set of parentheses matched or not. If they did, that is, if subject started with an opening parenthesis, the condition is true, and so the yes-pattern is executed and a closing parenthesis is required. Otherwise, since no-pattern is not present, the subpattern matches nothing. In other words, this pattern matches a sequence of nonparentheses, optionally enclosed in parentheses.

If the condition is the string (R), it is satisfied if a recursive call to the pattern or subpattern has been made. At “top level”, the condition is false. This is a PCRE extension. Recursive patterns are described in the next section.

If the condition is not a sequence of digits or (R), it must be an assertion. This may be a positive or negative lookahead or lookbehind assertion. Consider this pattern, again containing nonsignificant white space, and with the two alternatives on the second line:

```
(?(?=[ ^a-z ]*[ a-z ])\d{2}-[ a-z ]{3}-\d{2}    |    \d{2}-\d{2}-\d{2})
```

The condition is a positive lookahead assertion that matches an optional sequence of nonletters followed by a letter. In other words, it tests for the presence of at least one letter in the subject. If a letter is found, the subject is matched against the first alternative; otherwise it is matched against the second. This pattern matches strings in one of the two forms dd-aaa-dd or dd-dd-dd, where aaa are letters and dd are digits.

Regular Expression Comments

The sequence (?# marks the start of a comment that continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part in the pattern matching at all.

Recursive Patterns

Consider the problem of matching a string in parentheses, allowing for unlimited nested parentheses. Without the use of recursion, the best that can be done is to use a pattern that matches up to some fixed depth of nesting. It is not possible to handle an arbitrary nesting depth. Perl provides a facility that allows regular expressions to recurse (amongst other things). It does this by interpolating Perl code in the expression at runtime, and the code can refer to the expression itself. A Perl pattern to solve the parentheses problem can be created like this:

```
$re = qr{\( (?:(?>[ ^ ( ) ]+ ) | (?p{$re}) ) * \)}x;
```

The (?p{...}) item interpolates Perl code at runtime, and in this case refers recursively to the pattern in which it appears. Obviously, PCRE cannot support the interpolation of Perl code. Instead, it supports some special syntax for recursion of the entire pattern, and also for individual subpattern recursion.

The special item that consists of (? followed by a number greater than zero and a closing parenthesis is a recursive call of the subpattern of the given number, provided that it occurs inside that subpattern. (If not,

Chapter IV-7 — Programming Techniques

it is a “subroutine” call, which is described in **Subpatterns as Subroutines** on page IV-141.) The special item `(?R)` is a recursive call of the entire regular expression.

For example, this PCRE pattern solves the nested parentheses problem (additional nonfunction whitespace has been added to separate the expression into parts):

```
\( ( (?>[^( )]+) | (?R) )* \)
```

First it matches an opening parenthesis. Then it matches any number of substrings which can either be a sequence of nonparentheses, or a recursive match of the pattern itself (that is a correctly parenthesized substring). Finally there is a closing parenthesis.

If this were part of a larger pattern, you would not want to recurse the entire pattern, so instead you could use this:

```
( \ ( ( (?>[^( )]+) | (?1) )* \ ) )
```

We have put the pattern into parentheses, and caused the recursion to refer to them instead of the whole pattern. In a larger pattern, keeping track of parenthesis numbers can be tricky. It may be more convenient to use named parentheses instead. For this, PCRE uses `(?P>name)`, which is an extension to the Python syntax that PCRE uses for named parentheses (Perl does not provide named parentheses). We could rewrite the above example as follows:

```
(?P<pn> \ ( ( (?>[^( )]+) | (?P>pn) )* \ ) )
```

This particular example pattern contains nested unlimited repeats, and so the use of atomic grouping for matching strings of nonparentheses is important when applying the pattern to strings that do not match. For example, when this pattern is applied to

```
(aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa( )
```

it yields “no match” quickly. However, if atomic grouping is not used, the match runs for a very long time indeed because there are so many different ways the `+` and `*` repeats can carve up the subject, and all have to be tested before failure can be reported.

At the end of a match, the values set for any capturing subpatterns are those from the outermost level of the recursion at which the subpattern value is set. If you want to obtain intermediate values, a callout function can be used (see **Subpatterns as Subroutines** on page IV-141). If the pattern above is matched against

```
(ab(cd)ef)
```

the value for the capturing parentheses is “ef”, which is the last value taken on at the top level. If additional parentheses are added, giving

```
\( ( ( (?>[^( )]+) | (?R) )* ) \)
    ↑                               ↑
```

the string they capture is “ab(cd)ef”, the contents of the top level parentheses. If there are more than 15 capturing parentheses in a pattern, PCRE has to obtain extra memory to store data during a recursion, which it does by using `pcre_malloc`, freeing it via `pcre_free` afterward. If no memory can be obtained, the match fails with the `PCRE_ERROR_NOMEMORY` error.

Do not confuse the `(?R)` item with the condition `(R)`, which tests for recursion. Consider this pattern, which matches text in angle brackets, allowing for arbitrary nesting. Only digits are allowed in nested brackets (that is, when recursing), whereas any characters are permitted at the outer level.

```
< (? : (? (R) \d++ | [ ^<> ]*+ ) | (?R) ) * >
```

In this pattern, `(? (R)` is the start of a conditional subpattern, with two different alternatives for the recursive and nonrecursive cases. The `(?R)` item is the actual recursive call.

Subpatterns as Subroutines

If the syntax for a recursive subpattern reference (either by number or by name) is used outside the parentheses to which it refers, it operates like a subroutine in a programming language. An earlier example pointed out that the pattern

```
(sens|respons)e and \libility
```

matches “sense and sensibility” and “response and responsibility”, but not “sense and responsibility”. If instead the pattern

```
(sens|respons)e and (?1)ibility
```

is used, it does match “sense and responsibility” as well as the other two strings. Such references must, however, follow the subpattern to which they refer.

Regular Expressions References

The regular expression syntax supported by **Grep**, **GrepString**, **GrepList**, and **SplitString** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <http://pcre.org/> for more information about the PCRE library, and <http://www.perldoc.com/> for more about Perl regular expressions. This description, Regular Expressions In Igor, is taken from the PCRE documentation.

A good book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

Working with Files

Here are the built-in operations that you can use to read from or write to files:

Operation	What It Does
Open	Opens an existing file for reading or writing. Can also create a new file. Can also append to an existing file. Returns a file reference number that you must pass to the other file operations. Use Open/D to present a dialog that allows the user to choose a file without actually opening the file.
fprintf	Writes formatted text to an open file.
wfprintf	Writes wave data as formatted text to an open file.
FSetPos	Sets the position at which the next file read or write will be done.
FStatus	Given a file reference number, returns miscellaneous information about the file.
FBinRead	Reads binary data from a file into an Igor string, variable or wave. This is used mostly to read nonstandard file formats.
FBinWrite	Writes binary data from an Igor string, variable or wave. This is used mostly to write nonstandard file formats.
FReadLine	Reads a line of text from a text file into an Igor string variable. This can be used to parse an arbitrary format text file.
Close	Closes a file opened by the Open operation.

Before working with a file, you must use the Open operation to obtain a file reference number that you use with all the remaining commands. The Open operation creates new files, appends data to an existing file, or reads data from an existing file. There is no facility to deal with the resource fork of a Macintosh file.

Chapter IV-7 — Programming Techniques

Sometimes you may write a procedure that uses the Open operation and the Close operation but, because of an error, the Close operation never gets to execute. You then correct the procedure and want to rerun it. The file will still be open because the Close operation never got a chance to run. In this case, execute:

Close/A

from the command line to close all open files.

Finding Files

The TextFile and IndexedFile functions help you to determine what files exist in a particular folder. IndexedFile is just a more general version of TextFile.

You can also use the Open operation with the /D flag to present an open dialog.

Other File- and Folder-Related Operations and Functions

Igor Pro also supports a number of operations and functions for file or folder manipulation:

CopyFile	CopyFolder
DeleteFile	DeleteFolder
GetFileFolderInfo	SetFileFolderInfo
MoveFile	MoveFolder
CreateAliasShortcut	
NewPath	PathInfo
ParseFilePath	

Warning: Use caution when writing code that deletes or moves files or folders. These actions are not undoable.

Because the DeleteFolder, CopyFolder and MoveFolder operations have the potential to do a lot of damage if used incorrectly, they require user permission before overwriting or deleting a folder. The user controls the permission process using the Miscellaneous Settings dialog (Misc menu).

Writing to a Text File

You can generate output text files from Igor procedures or from the command line in formats acceptable to other programs. To do this, you need to use the **Open** and **Close** operations and the **fprintf** operation (page V-165) and the **wfprintf** operation (page V-657).

The following commands illustrate how you could use these operations to create an output text file. Each operation is described in detail in following sections:

```
Variable f1                                //make refNum variable
Open f1 as "A New File"                    //create and open file
fprintf f1, "wave1\twave2\twave3\r"        //write column headers
wfprintf f1, "" wave1, wave2, wave3        //write wave data
Close f1                                    //close file
```

Open and Close Operations

You use the **Open** operation (page V-406) to open a file. For our purposes, the syntax of the Open operation is:

Open [/R/A/P=*pathName*/M=*messageStr*] *variableName* [as "filename"]

variableName is the name of a numeric variable. The Open operation puts a file reference number in that variable. You will need the reference number to access the file after you've opened it.

A file specifications consists of a path (directions for finding a folder) and a file name. In the Open operation, you can specify the path in three ways:

Using a full path as the filename parameter:

```
Open refNum as "hd:Data:Run123.dat"
```

Or using a symbolic path name and a file name:

```
Open/P=DataPath refNum as "Run123.dat"
```

Or using a symbolic path name and a partial path including the file name:

```
Open/P=HDPATH refNum as ":Data:Run123.dat"
```

A symbolic path is a short name that refers to a folder on disk. See **Symbolic Paths** on page II-30.

If you do not provide enough information to find the folder and file of interest, Igor puts up a dialog which lets you select the file to open. If you supply sufficient information, Igor will just open the file without putting up the dialog.

To open a file for reading, use the /R flag. To add new data to a file, use the /A flag. If you omit both of these flags, you will overwrite any data that is already in the file.

If you open a file for writing (you don't use /R) then, if there exists a file with the specified name, Igor opens the file and overwrites the existing data in the file. If there is no file with the specified name, Igor creates a new file.

Warning: If you're not careful you can inadvertently lose data using the Open operation by opening for writing without using the /A flag. To avoid this, use the /R (open for read) or /A (append) flags.

Wave Reference Functions

It is common to write a user-defined function that operates on all of the waves in a data folder, on the waves displayed in a graph or table, or on a wave identified by a cursor in a graph. For these purposes, you need to use wave reference functions.

Wave reference functions are built-in Igor functions that return a reference that can be used in a user-defined function. Here is an example that works on the top graph. Cursors are assumed to be placed on a region of a trace in the graph.

```
Function WaveAverageBetweenCursors()
    WAVE/Z w = CsrWaveRef(A)
    if (!WaveExists(w))          // Cursor is not on any wave.
        return NaN
    endif

    Variable xA = xcsr(A)
    Variable xB = xcsr(B)
    Variable avg = mean(w, xA, xB)

    return avg
End
```

CsrWaveRef returns a wave reference that identifies the wave a cursor is on.

An older function, CsrWave, returns the *name* of the wave the cursor is on. It would be tempting to use this to determine the wave the cursor is on, but it would be incorrect. The name of a wave by itself does not uniquely identify a wave because it does not specify the data folder in which the wave resides. For this reason, we usually need to use the wave reference function CsrWaveRef instead of CsrWave.

This example uses a wave reference function to operate on the waves displayed in a graph:

```
Function SmoothWavesInGraph()
    String list = TraceNameList("", ";", 1)
    String traceName
    Variable index = 0
    do
```

Chapter IV-7 — Programming Techniques

```
        traceName = StringFromList(index, list)
        if (strlen(traceName) == 0)
            break          // No more traces.
        endif
        WAVE w = TraceNameToWaveRef("", traceName)
        Smooth 5, w
        index += 1
    while(1)
End
```

Here are the wave reference functions. See Chapter V-1, **Igor Reference**, for details on each of them.

Function	Comment
CsrWaveRef	Returns a reference to the Y wave to which a cursor is attached.
CsrXWaveRef	Returns a reference to the X wave when a cursor is attached to an XY pair.
WaveRefIndexed	Returns a reference to a wave in a graph or table or to a wave in the current data folder.
XWaveRefFromTrace	Returns a reference to an X wave in a graph. Used with the output of TraceNameList.
ContourNameToWaveRef	Returns a reference to a wave displayed as a contour plot. Used with the output of ContourNameList.
ImageNameToWaveRef	Returns a reference to a wave displayed as an image. Used with the output of ImageNameList.
TraceNameToWaveRef	Returns a reference to a wave displayed as a waveform or as the Y wave of an XY pair in a graph. Used with the output of TraceNameList.
TagWaveRef	Returns a reference to a wave to which a tag is attached in a graph. Used in creating a smart tag.

It is possible to create a user-defined function that returns a wave reference via a structure parameter. For simple applications, it may be easier to create a string function that returns a full path to the wave. Here is an example:

```
Function/S CursorAWave()
    WAVE/Z w= CsrWaveRef(A)
    if (WaveExists(w)==0)
        return ""
    endif
    return GetWavesDataFolder(w,2)
End

Function DemoCursorAWave()
    WAVE/Z w= $CursorAWave()
    if (WaveExists(w)==0)
        Print "oops: no wave"
    else
        Print "Cursor A is on the wave", WaveName(w)
    endif
End
```

DemoCursorAWave uses the \$ operator to convert the full path to the wave returned by CursorAWave into a wave reference stored in w.

Processing Lists of Waves

Igor users often want to use a string list of waves in places where Igor is looking for just the name of a single wave. For example, they would like to do this:

```
Display "wave0;wave1;wave2"
```

or, more generally:

```
Function DisplayListOfWaves(list)
    String list          // e.g., "wave0;wave1;wave2"

    Display $list
End
```

Unfortunately, Igor can't handle this. However, there are techniques for achieving the same result.

Graphing a List of Waves

This example illustrates the basic technique for processing a list of waves.

```
Function DisplayWaveList(list)
    String list          // A semicolon-separated list.

    String theWave
    Variable index=0

    do
        // Get the next wave name
        theWave = StringFromList(index, list)
        if (strlen(theWave) == 0)
            break          // Ran out of waves
        endif
        if (index == 0)    // Is this the first wave?
            Display $theWave
        else
            AppendToGraph $theWave
        endif
        index += 1
    while (1)             // Loop until break above
End
```

To make a graph of all of the waves in the current data folder, you would execute

```
DisplayWaveList(WaveList("*", ";", ""))
```

Operating on the Traces in a Graph

In a previous section, we showed an example that operates on the waves displayed in a graph. It used a wave reference function, `TraceNameToWaveRef`. If you want to write a function that operates on *traces* in a graph, you would *not* use wave reference functions. That's because Igor operations that operate on *traces* expect *trace names*, not wave references. For example:

```
Function GrayOutTracesInGraph()
    String list = TraceNameList("", ";", 1)
    String traceName
    Variable index = 0
    do
        traceName = StringFromList(index, list)
        if (strlen(traceName) == 0)
            break          // No more traces.
        endif

        // WRONG: ModifyGraph expects a trace name and w is not a trace name
        WAVE w = TraceNameToWaveRef("", traceName)
        ModifyGraph rgb(w)=(50000,50000,50000)

        // RIGHT
        ModifyGraph rgb($traceName)=(50000,50000,50000)

        index += 1
    while(1)
End
```

Using a Fixed-Length List

In the previous examples, the number of waves in the list was unimportant and all of the waves in the list served the same purpose. In this example, the list has a fixed number of waves and each wave has a different purpose.

```
Function DoLineFit(list)
    String list          // List of waves names: source, dest, weight
    String source, dest, weight

    // Pick out the expected wave names
    source = StringFromList(0, list)
    dest = StringFromList(1, list)
    weight = StringFromList(2, list)

    CurveFit line $source /D=$dest /W=$weight
End
```

You would invoke this function as follows:

```
DoLineFit("wave0;wave1;wave2")
```

Operating on Qualified Waves

This example illustrates how to operate on waves that match a certain criterion. It is broken into two functions - one that creates the list of qualified waves and a second that operates on them. This organization gives us a general purpose routine (ListOfMatrices) that we would not have if we wrote the whole thing as one function.

```
Function/S ListOfMatrices()
    String list = ""
    Variable index=0
    do
        WAVE/Z w=WaveRefIndexed("",index,4)    // Get next wave.
        if (WaveExists(w) == 0)
            break                               // No more waves.
        endif
        if (DimSize(w,1)>0 && DimSize(w,2)==0)
            // Found matrix. Add to list with separator.
            list += NameOfWave(w) + ";"
        endif
        index += 1
    while(1)                                     // Loop till break above.
    return list
End
```

```
Function ChooseAndDisplayMatrix()
    String theList = ListOfMatrices()

    String theMatrix
    Prompt theMatrix, "Matrix to display:", popup theList
    DoPrompt "Display Matrix", theMatrix
    if (V_Flag != 0)
        return -1
    endif

    WAVE m = $theMatrix
    NewImage m
End
```

The ExecuteCmdOnList Function

The ExecuteCmdOnList function is implemented by a WaveMetrics procedure file and executes any command for each wave in the list. For example, the following commands do a WaveStats operation on each wave.

```
Make wave0=gnoise(1), wave1=gnoise(10), wave2=gnoise(100)
ExecuteCmdOnList("WaveStats %s", "wave0;wave1;wave2;")
```

The `ExecuteCmdOnList` function is supplied in the `Execute Cmd On List` procedure file. See **The Include Statement** on page IV-119 for instructions on including a procedure file.

This technique is on the kludgy side. If you can achieve your goal in a more straightforward fashion without heroic efforts, you should use regular programming techniques.

The Execute Operation

`Execute` is a built-in operation that executes a string expression as if you had typed it into the command line. The main purpose of `Execute` is to get around the restrictions on calling macros and external operations from user functions.

We try to avoid using `Execute` because it makes code obscure and difficult to debug. If you can write a procedure without `Execute`, do it. However, there are some cases where using `Execute` can save pages of code or achieve something that would otherwise be impossible.

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the `Execute` operation. Use this to print the string to the history for debugging. For example:

```
String cmd
sprintf cmd, "GBLoadWave/P=%s/S=%d \"%s\"", pathName, skipCount, fileName
Print cmd          // For debugging
Execute cmd
```

It is not necessary to use `Execute` to call the `GBLoadWave` external operation because it can be called directly from a user function. Prior to Igor Pro 5, this was not possible.

When you use `Execute`, you must be especially careful in the handling of wave names. See **Programming with Liberal Names** on page IV-121 for details.

When `Execute` runs, it is as if you typed a command in the command line. Local variables in macros and functions are not accessible. The example in **Calling an External Operation From a User-Defined Function** on page IV-147 shows how to use the `sprintf` operation to solve this problem.

Using a Macro From a User-Defined Function

A macro can not be called directly from a user function. To do so, we must use `Execute`. This is a trivial example for which we would normally not resort to `Execute` but which clearly illustrates the technique.

```
Function Example()
    Make wave0=enoise(1)
    Variable/G V_avg          // Create a global
    Execute "MyMacro(\"wave0\")" // Invokes MyMacro("wave0")
    return V_avg
End

Macro MyMacro(wv)
    String wv
    WaveStats $wv          // Sets global V_avg and 9 other local vars
End
```

`Execute` does not supply good error messages. If the macro generates an error, you may get a cryptic message. Therefore, debug the macro *before* you call it with the `Execute` operation.

Calling an External Operation From a User-Defined Function

Prior to Igor Pro 5, external operations could not be called directly from user-defined functions and had to be called via `Execute`. Now it is possible to write an external operation so that it can be called directly. However, old XOPs that have not been updated still need to be called through `Execute`. This example shows how to do it.

If you attempt to directly use an external operation which does not support it, you will see an error dialog telling you to use `Execute` for that operation.

Chapter IV-7 — Programming Techniques

The external operation in this case is VDTWrite which sends text to the serial port. It is implemented by the VDT XOP.

```
Function SetupVoltmeter(range)
    Variable range      // .1, .2, .5, 1, 2, 5 or 10 volts

    String voltmeterCmd
    sprintf voltmeterCmd, "DVM volts=%g", range
    String vdtCmd
    sprintf vdtCmd "VDTWrite \"%s\"\\r\\n", voltmeterCmd
    Execute vdtCmd
End
```

In this case, we are sending the command to a voltmeter that expects something like:

```
DVM volts=.2<CR><LF>
```

to set the voltmeter to the 0.2 volt range.

The parameter that we send to the Execute operation is:

```
VDTWrite "DVM volts=.2\\r\\n"
```

The backslashes used in the second sprintf call insert two quotation marks, a carriage return, and a linefeed in the command about to be executed.

A new VDT2 XOP exists which includes external operations that *can* be directly called from user-functions. Thus, new programming should use the VDT2 XOP and will not need to use Execute.

Other Uses of Execute

Execute can also accept as an argument a string variable containing commands that are algorithmically constructed. Here is a simple example:

```
Function Fit(w, fitType)
    WAVE w                // Source wave
    String fitType        // One of the built-in Igor fit types

    String name = NameOfWave(w)
    name = PossiblyQuoteName(name)    // Liberal names need quotes

    String cmd
    sprintf cmd, "CurveFit %s %s", fitType, name
    Execute cmd
End
```

Use this function to do any of the built-in fits on the specified wave. Without using the Execute operation, we would have to write it as follows:

```
Function Fit(w, fitType)
    WAVE w                // Source wave
    String fitType        // One of the built-in Igor fit types

    strswitch(fitType)
        case "line":
            CurveFit line w
            break

        case "exp":
            CurveFit exp w
            break

        <and so on for each fit type>
    endswitch
End
```

Note the use of `sprintf` to prepare the string containing the command to be executed. The following would not work because when `Execute` runs, local variables and parameters are not accessible:

```
Execute "CurveFit fitType name"
```

Deferred Execution Using the Operation Queue

It is sometimes necessary to execute a command after the current function has finished. This is done using the `Execute/P` operation. For details, see **Operation Queue** on page IV-195.

Procedures and Preferences

You can set many preferences. Most of the preferences control the style of new objects, including new graphs, traces and axes added to graphs, new tables, columns added to tables and so on.

Preferences are usually used only for manual “point-and-click” operation. We usually don’t want preferences to affect the behavior of procedures. The reason for this is that we want a procedure to do the same thing no matter who runs it. Also, we want it to do the same thing tomorrow as it does today. If we allowed preferences to take effect during procedure execution, a change in preferences could change the effect of a procedure, making it unpredictable.

By default, preferences do not take effect during procedure execution. If you want to override the default behavior, you can use the `Preferences` operation. From within a procedure, you can execute “`Preferences 1`” to turn preferences on. This affects the procedure and any subroutines that it calls. It stays in effect until you execute “`Preferences 0`”.

When a *macro* ends, the state of preferences reverts to what it was when that macro started. If you change the preference setting within a *function*, the preferences state does *not* revert when that function ends. You must turn preferences on, save the old preferences state, execute Igor operations, and then restore the preferences state. For example:

```
Function AppendWithCapturedAxis()
    Variable oldPrefState
    Preferences 1;                // Turn preferences on and
    oldPrefState = V_Flag         // save the old state.

    Make wave0=x
    Display/L=myCapturedAxis wave0 // myCapturedAxis is pref axis.

    Preferences oldPrefState      // Restore old prefs state.
End
```

Experiment Initialization Procedures

When Igor loads an experiment, it checks to see if there are any commands in the procedure window before the first macro, function or menu declaration. If there are such commands Igor executes them. This provides a way for you to initialize things. These initialization commands can invoke procedures that are declared later in the procedure window.

Also see **BeforeFileOpenHook** on page IV-202 and **IgorStartOrNewHook** on page IV-206 for other initialization methods.

Procedure Subtypes

A procedure subtype identifies the purpose for which a particular procedure is intended and the appropriate menu from which it can be chosen. For example, the `Graph` subtype puts a procedure in the `Graph` Macros submenu of the `Windows` menu.

```
Window Graph0() : Graph
    PauseUpdate; Silent 1      // building window...
```

Chapter IV-7 — Programming Techniques

```
Display/W=(5,42,400,250) wave0,wave1,wave2  
<more commands>
```

End

When Igor automatically creates a procedure, for example when you close and save a graph, it uses the appropriate subtype. When you create a curve fitting function using the Curve Fitting dialog, the dialog automatically uses the FitFunc subtype. You usually don't need to use subtypes for procedures that you write.

This table shows the available subtypes and how they are used.

Subtype	Effect	Available for
Graph	Displayed in Graph Macros submenu.	Macros
GraphStyle	Displayed in Graph Macros submenu and in Style pop-up menu in New Graph dialog.	Macros
GraphMarquee	Displayed in graph marquee. This keyword is no longer recommended. See Marquee Menu as Input Device on page IV-115 for details.	Macros and functions
Table	Displayed in Table Macros submenu.	Macros
TableStyle	Displayed in Table Macros submenu and in Style pop-up menu in New Table dialog.	Macros
Layout	Displayed in Layout Macros submenu.	Macros
LayoutStyle	Displayed in Layout Macros submenu and in Style pop-up menu in New Layout dialog.	Macros
LayoutMarquee	Displayed in layout marquee. This keyword is no longer recommended. See Marquee Menu as Input Device on page IV-115 for details.	Macros and functions
Panel	Displayed in Panel Macros submenu.	Macros

SetVariableControl	Displayed in Procedure pop-up menu in SetVariable Control dialog.	Macros and functions

Memory Considerations

The maximum amount of memory available to Igor Pro (or any application) is 4 GB on Macintosh and 2, 3, or 4 GB on Windows regardless of the amount of installed RAM. Virtual memory on disk is always used, being constrained only by available disk space and access speed. See **Memory Management** on page III-408 for more information.

These memory limits are adequate for most applications although you may be surprised by out of memory errors with much less apparent memory usage. Oftentimes such errors are caused by fragmentation of RAM and the inability of either operating system to combine adjacent blocks of deallocated memory to create a contiguous memory block.

Most often such memory fragmentation occurs when you create and destroy many large waves during function execution. The best way to avoid these memory problems is to create these large waves once at the start of your function and then reuse them rather than killing and remaking them. The reason is that if you use Redimension

to shrink a large wave, then a following Redimension that increases the wave size should succeed as it will be expanding back into the same memory block. You can also use Make/O can in place of Redimension.

Wave Reference Counting

The method Igor Pro uses to deallocate memory when waves are killed was improved in Igor Pro 6. The new method uses reference counting to determine when a wave is no longer referenced anywhere and memory can be safely deallocated, which should reduce the likelihood of out of memory errors, especially on Macintosh.

Because memory is not deallocated until all references to a given wave are gone, memory may not be freed when you think. Consider the function:

```
Function myfunc()
    Make/N=10E6 bigwave
    // do stuff
    FunctionThatKillsBigwave()
    // do more stuff
End
```

The memory allocated for bigwave is not deallocated until the function returns because an automatic WAVE reference variable of the same name still references the wave. To free memory for the second part, use the **WAVEClear** operation (page V-645):

```
Function myfunc()
    Make/N=10E6 bigwave
    // do stuff
    FunctionThatKillsBigwave()
    WAVEClear bigwave
    // do more stuff
End
```

The WAVEClear command takes a list of WAVE reference variables and stores NULL into them. It is the same as:

```
WAVE/Z wavref= $"
```

If you see the message “BUG: DecrementWaveRefCount” printed in the history area, please notify support@wavemetrics.com. If possible, please provide the steps necessary to reproduce the message.

If you suspect the new method is causing problems (a crash could occur if a reference was missed and a killed wave was accessed,) you can revert to the old method by executing

```
SetIgorOption doWAVERefCount= 0
```

You should do this in a blank experiment because it affects function compiling. You can revert to the new method by restarting Igor Pro or by executing

```
SetIgorOption doWAVERefCount= 2.
```

Creating Igor Extensions

Igor includes a feature that allows a C or C++ programmer to extend its capabilities. Using Metrowerks CodeWarrior, Apple’s Xcode or Microsoft Visual C++, a programmer can add command line operations and functions to Igor. These are called external operations and external functions. Experienced programmers can also add menu items, dialogs and windows.

A file containing external operations or external functions is called an “XOP file” or “XOP” (pronounced “ex-op”) for short.

Here are some things for which you might want to write an XOP:

- To do number-crunching on waves.
- To import data from a file format that Igor does not support.
- To acquire data directly into Igor waves.

- To communicate with a remote computer, instrument or database.

The main reasons for writing something as an XOP instead of writing it as an Igor procedure are:

- It needs to be blazing fast.
- You already have a lot of C code that you want to reuse.
- You need to call drivers for data acquisition.
- It requires programming techniques that Igor doesn't support.
- You want to add your own dialogs or windows.

Writing an XOP that does number-crunching is considerably easier than writing a stand-alone program. You don't need to know anything about the Macintosh Toolbox or the Windows API. Writing an XOP that adds dialogs or windows to Igor requires more knowledge but is still easier than writing a stand-alone program.

If you are a C or C++ programmer and would like to extend Igor with your own XOP, you will need to purchase the Igor External Operations Toolkit from WaveMetrics. This toolkit contains documentation on writing XOPs as well as the source code for many of the WaveMetrics sample XOPs. It supplies a large library of routines that enable communication between Igor and the external code. You will also need the a recent version of CodeWarrior, Xcode, or Microsoft Visual C++.

Debugging Procedures

There are two techniques for debugging procedures in Igor:

- Using print statements
- Using the symbolic debugger

For most situations, the symbolic debugger is the most effective tool. In some cases, a strategically placed print statement is sufficient.

Debugging With Print Statements

This technique involves putting print statements at a certain point in a procedure to display debugging messages in Igor's history area. In this example, we use `Printf` to display the value of parameters to a function and then `Print` to display the function result.

```
Function Test(w, num, str)
    Wave w
    Variable num
    String str

    Printf "Wave=%s, num=%g, str=%s\r", NameOfWave(w), num, str

    <body of function>

    Print result
    return result
End
```

See **Creating Formatted Text** on page IV-184 for details on the `Printf` operation.

The Debugger

When a procedure doesn't produce the results you want, you can use Igor's built-in debugger to observe the execution of user-defined macros and functions while single-stepping through the lines of code.

The debugger is normally disabled. Enable it using either the Procedure menu or by Control-clicking (Macintosh) or right-clicking (Windows) in any procedure window to get the pop-up menu:

Procedure Menu

Contextual menu

The debugger window will automatically appear when one of the following events occurs:

1. A breakpoint that you previously set is encountered.
2. An error occurs, and you have enabled debugging on that kind of error.
3. An error dialog is presented, and you click the Debug button.

Setting Breakpoints

When you want to observe a particular routine in action, set a breakpoint on the line where you want the debugger to appear. To do this, open the procedure window which contains the routine, and click in the left “breakpoint margin”. The breakpoint margin appears only if the debugger has been enabled:

Debugger Disabled

Debugger Enabled

When a line of code marked with the red dot (denoting a set breakpoint) is about to execute, the debugger window will appear.

Click the red dot again to clear the breakpoint. Control-click (*Macintosh*) or right-click (*Windows*) and use the pop-up menu to clear all breakpoints or disable a breakpoint on the currently selected line of the procedure window.

Debugging on Error

You can automatically open the debugger window when an error occurs. There are two categories of errors to choose from:

Debug On Error	Any runtime error except failed NVAR, SVAR, or WAVE references.
NVAR SVAR WAVE Checking	Failed NVAR, SVAR, or WAVE references.

You can use the /Z flag to hide failures from SVAR, NVAR and WAVE checking. This is appropriate where the reference is subsequently checked with WaveExists, NVAR_Exists, or SVAR_Exists:

```
WAVE/Z wv=<pathToPossiblyMissingWave>
```

```
if( WaveExists(wv) )
  <do something with wv>
endif
```

See **Runtime Lookup of Globals** on page IV-50 for details.

Chapter IV-8 — Debugging

Use the Procedure or pop-up menus to choose either or both error categories. If the selected error occurs, the debugger will open and an error message will appear in the debugger window's status area. The error message was generated by the command *above* the yellow arrow:

Macro Execute Error: The Debug Button

When the debugger is enabled and an error occurs in a Macro, an error dialog is presented that will (usually) have a Debug button in it. Click the button to open the debugger window.

Errors in macros (or procs) are reported immediately after they occur.

When an error is reported by a function, a different dialog appears long after the error was actually committed. The Debug On Error option catches errors in functions immediately after they are committed.

Stepping Through Your Code

Begin by enabling the debugger and setting a breakpoint on the line of code you are interested in, or begin when the debugger automatically opens because of an error. Use the buttons at the top of the debugger window to step through your code:

The Stop button ceases execution of the running function or macro before it completes. This is equivalent to clicking Igor's Abort button (*Windows*) or pressing Command-period (*Macintosh*) while the procedure is running.

Keyboard shortcuts: (none)

Note: Pressing Command-period on a Macintosh while the debugger window is showing is equivalent to clicking the Go button, not the Stop button.

The Step Over button executes the next line. If the line contains a call to one or more subroutines, execution continues until the subroutines return or until an error or breakpoint is encountered. Upon return, execution halts until you click a different button.

Keyboard shortcuts: Enter, keypad Enter, or Return

The Step Into button executes the next line. If that line contains a call to one or more subroutines, execution halts when the first subroutine is entered. The Stack list of currently executing routines shows the most recently entered routine as the last item in the list.

Keyboard shortcuts: +, =, or keyPad +

The Step Out button executes until the current subroutine is exited, or an error or breakpoint is encountered.

Keyboard shortcuts: -, _ (underscore) or keypad -

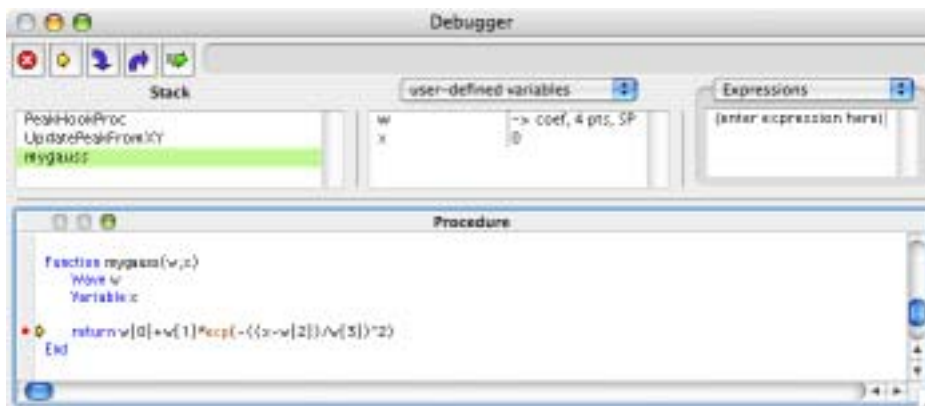

The Go button resumes program execution. The debugger window remains open until execution completes or an error or breakpoint is encountered.

Keyboard shortcuts: Esc

The Stack and Variables Lists

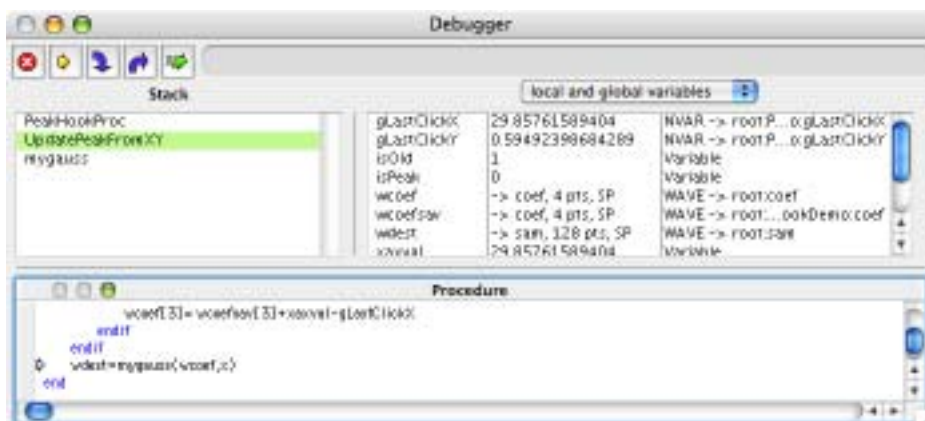

The Stack List shows the routine that is currently executing and the chain of routines that called it. The top item in the list is the routine that began execution and the bottom item is the routine which is currently executing.

In this example, the routine that started execution is PeakHookProc, which most recently called UpdatePeakFromXY, which then called the currently executing mygauss user function.

The Variables List (to the right of the Stack List) shows that the function parameters w and x have the values coef (a wave) and 0 (a number). The pop-up menu controls which variables are displayed in the list; the example shows only user-defined local variables.

You can examine the variables associated with any routine in the Stack List by simply selecting the routine:

Chapter IV-8 — Debugging

Here we've selected UpdatePeakFromXY, the routine that called mygauss (see the light blue arrow). Notice that the Variables List is showing the variables that are local to UpdatePeakFromXY.

For illustration purposes, the Variables List has been resized by dragging the dividing line, and the pop-up menu has been set to show local and global variables and type information.

The Variables List Columns

The Variables List shows either two or three columns, depending on whether the “show variable types” item in the Variable pop-up menu is checked.

The first column is the name of the local variable. Note that the name of an NVAR, SVAR, or WAVE reference is a local name referring to a global object.

The second column is the value of the local variable. Double-click the second column to edit strings or variables.

In the case of a wave, the size and precision of the wave are shown here. The “->” characters mean “refers to”. In our example wcoef is a local name that refers to a (global) wave named coef, which is one-dimensional, has 4 points, and is single precision.

To determine the value of a particular wave element, use the **Wave, Structures, and Expressions Pane** on page IV-160.

The third (optional) column shows what the type of the variable is, whether Variable, String, NVAR, SVAR, or WAVE. For global references, the full path (including the data folder) to the global is shown.

Note: The currentDF item is separated by a dashed line because currentDF is not really a global variable; it is a convenient name to identify the current data folder. See Chapter II-8, **Data Folders**, for more information about data folders.

Variables Pop-Up Menu

The Variables pop-up menu controls which information is displayed in the Variables List. The menu items differ when the routine chosen from the Stack List is a function or a macro/proc:

Pop-up Menu for Functions

Pop-up Menu for Macros,
Procs, and Windows

Function Variables

The SlowSumWaveFunction example below illustrates how different kinds of variables in functions are classified:

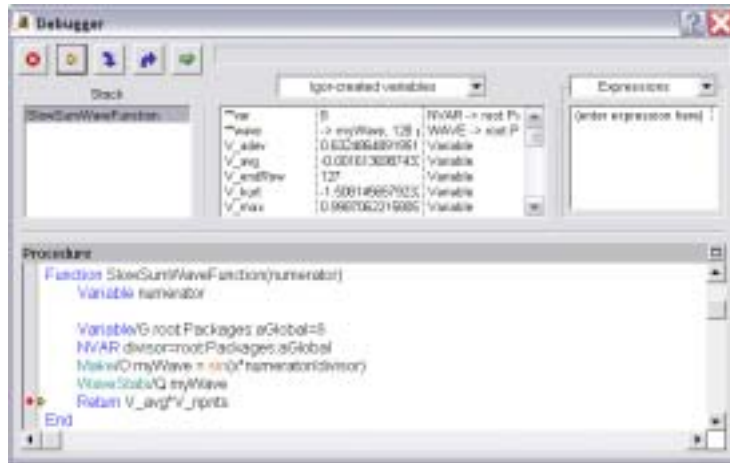

User-defined variables in functions include all items passed as parameters (numerator in this example) and any local strings and variables.

Local variables exist while a procedure is running, and cease to exist when the procedure returns; they never exist in a data folder like globals do.

NVAR, SVAR, WAVE, Variable/G and String/G references point to global variables, and therefore, aren't listed as user-defined (local) variables.

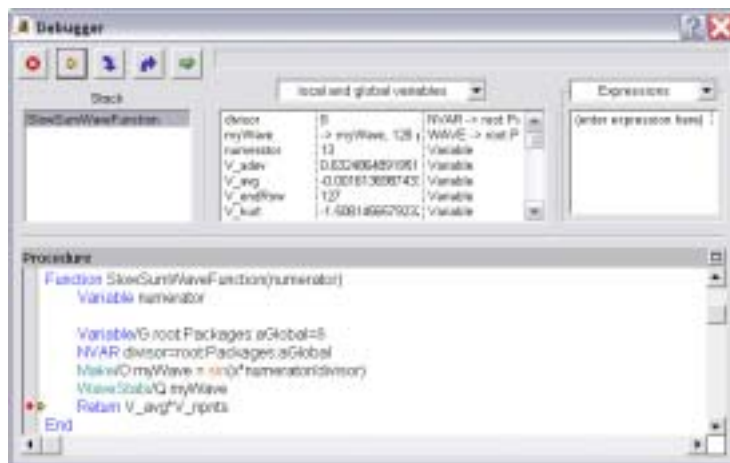

Use “Igor-created variables” to show local variables that Igor creates for functions when they call an operation or function that returns results in specially-named variables. The **WaveStats** operation (see page V-652), for example, defines V_adev, V_avg, and other variables to contain the statistics results:

Note: Some global references are created automatically for commands such as the Make operation; they have names that start with “***”. These are shown only when Igor-created variables is selected.

The “user- and Igor-created” menu item shows both kinds of local variables.

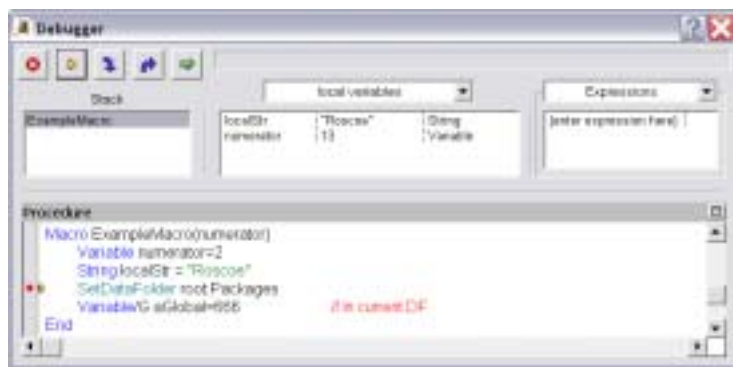

The “local and global variables” item shows user-created local variables, most Igor-created local variables, and references to global variables and waves through NVAR, SVAR, and WAVE references:

Choosing “local and global variables” also displays the current data folder at the end of the list as the mythical currentDF variable (see **The Variables List Columns** on page IV-158).

Macro Variables

The ExampleMacro below illustrates how variables in Macros, Procs or Window procedures are classified as locals or globals:

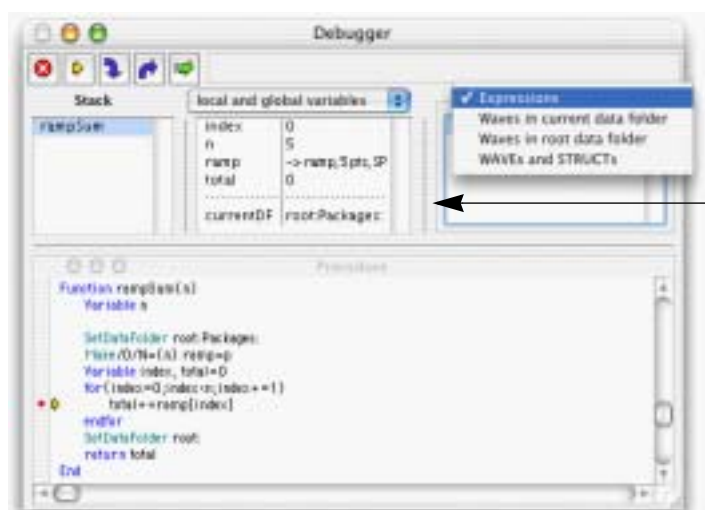

Local variables in macros include all items passed as parameters (numerator in this example) and local variables and local strings (localStr), and Igor-created local variables created by operations such as WaveStats.

Global variables in macros include all items in the current data folder, whether they are used in the macro or not. If the data folder changes because of a SetDataFolder operation, the list of global variables also changes. Note that there are no NVAR, SVAR, WAVE, or STRUCT references in a macro.

Wave, Structures, and Expressions Pane

The waves, structures, and expressions pane is on the right side of the variables list:

Drag this divider to show or hide the waves, structures, and expressions pane.

This pane is hidden when there isn't enough room or when the divider between the pane and the variables list is dragged all the way to the right. Drag the divider to the left to show the pane. You may need to widen the window to make room.

The pop-up menu controls what is shown in the pane:

Pop-up Menu Selection	Pane Contents
Expressions	Numeric or string expressions which are evaluated in the context of the selected function or macro.
Waves in current data folder	A list of waves in the current data folder and the contents of one selected wave.
Waves in root data folder	The same, but for the root: data folder.
WAVEs and STRUCTs	A list of WAVE and STRUCT references in the selected function. Disabled when a macro or proc is selected in the Stack list.

Expressions

Replace the “(enter expression here)” prompt:

by clicking it, typing a numeric or string expression, and pressing Return.

Adding an expression adds a blank row at the end of the list that can be double-clicked to enter another expression. You can edit any of the expressions by double-clicking and typing.

The expression can be removed by selecting it and pressing Delete or Backspace.

The result of the expression will be recomputed when stepping through procedures. The expressions are evaluated in the context of the currently selected procedure.

Global expressions are evaluated in the context of the current data folder, though you can specify the data folder explicitly as in the example below.

If an expression is invalid the result is shown as “?”:

The expressions are discarded when a new Igor experiment is opened or when Igor quits.

Waves in Current or Root Data Folder

The debugger shows the waves in the specified data folder. You can select one of the waves to inspect a one-dimensional portion.

Chapter IV-8 — Debugging

For a one-dimensional wave, you can specify the first row of the wave to display in the “Start Row:” control, or leave it blank to display starting with row 0. To look beyond the start of very long waves, you can enter a number or numeric expression into “Start Row:”

You can edit the value of a wave element by double-clicking the value column and editing the value there.

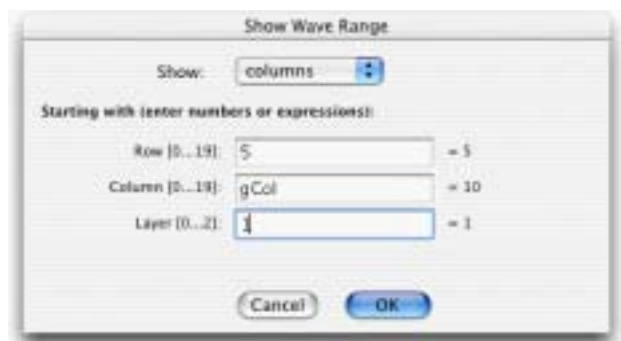

The wave value list will display only a limited number of rows, 1024 by default, in order to keep the debugger from being sluggish. When the list cannot display all of the rows, the last row in the list will say “(too many items)”. You can change the maximum number of rows displayed here with the SetIgorOption command:

`SetIgorOption DebuggerWaveRows=numRows`

Use the Start Row to bring the row you wish to inspect within view.

Multidimensional waves can also be viewed, but only a one-dimensional subset. To view a particular range of values use the “Range...” button (which appears only when a multidimensional wave is chosen in the pop-up menu) and the resulting Show Wave Range dialog:

Default: rows 0 ... n of column 0, layer 0

rows 5 ... of column 10, layer 1

WAVEs and STRUCTs

WAVE and STRUCT references are allowed only in functions, so this pop-up menu choice is disabled when the routine selected in the Stack list is a macro or proc.

A WAVE reference points to a global wave, which can be in any data folder.

A STRUCT reference points to a structure which exists on the runtime stack and does not exist as a global object in any data folder.

Each is composed of individual elements, and these can be inspected in the list in this pane.

Here's the code of an example contrived to demonstrate inspecting a structure's elements using the WAVES and STRUCTs pane:

```
Structure stuff
    String traces
    Variable nTraces
    STRUCT traceStuff trace[2]
EndStructure

Structure traceStuff
    Variable ndx
    String trace
    WAVE w
EndStructure

Function top(graph)
    String graph

    STRUCT stuff s

    s.traces=TraceNameList(graph, ";", 1 )
    s.nTraces= ItemsInList(s.traces)

    STRUCT traceStuff ts

    initTrace(ts, 0, graph, s.traces)
    s.trace[0]= ts

    initTrace(ts,1, graph, s.traces)          // breakpoint set here
    s.trace[1]= ts
End

Function initTrace(ts, index, graph, traces)
    STRUCT traceStuff &ts
    Variable index
    String graph, traces

    ts.ndx= index
    ts.trace= StringFromList(index,traces)
    WAVE ts.w=TraceNameToWaveRef(graph, ts.trace)
End
```

Running top("Graph0") with the breakpoint at the second initTrace call

results in the Variables list shown below. You can see in the Variables list that "s" is the name of structure of type "stuff":

Double-clicking the structure `s` row in the Variables list (or selecting `s` from the pop-up menu of WAVES and STRUCTs) displays the content of the structure.

You can see that the listing of the contents of a structure on a single line is of limited use!

To see the contents of STRUCT `traceStuff trace[0]`, double-click the `trace[0]` row in the WAVES and STRUCTs list:

You can edit the value of `ndx` and `trace` by double-clicking the second column.

To see the contents of `s.trace[0].w`, double-click `w`'s row:

You can edit the values of `myWave` by double-clicking the second column.

Use the pop-up menu to view previous levels of the `s` structure. When you choose the top-level ("`s`"), the menu will again be filled with all the WAVES and STRUCTs in the currently selected function.

The Procedure Pane

The procedure pane contains a copy of the procedure window of the routine selected in the Stack List. You can set and clear breakpoints in this pane just as you do in a procedure window, using the breakpoint margin and the Control-click (Macintosh) or right-click (Windows) menu.

A very useful feature of the debugger is the automatic text expression evaluator that shows the value of a variable or expression under the cursor. On the Macintosh, the value is displayed in the top-right corner of the debugger. On Windows, a tooltip is displayed near the cursor.

This is often faster than scrolling through the Variables List or entering an expression in the Expressions List to determine the value of a variable, wave, or structure member reference.

The value of a variable can be displayed whether or not the variable name is selected. To evaluate an expression such as "`wave[ii]+3`", the expression must be selected and the cursor must be over the selection.

The debugger won't evaluate expressions that include calls to user-defined functions; this prevents unintended side effects (a function could overwrite a wave's contents, for example). You can remove this limitation by creating the global variable `root:V_debugDangerously` and setting it to 1.

After You Find a Bug

Editing in the debugger window is disabled because the code is currently executing. Tracking down the routine after you've exited the debugger is easy if you follow these steps:

- 1) Scroll the debugger text pane back to the name of the routine you want to modify, and select it.
- 2) Control-click (*Macintosh*) or right-click (*Windows*) the name, and choose "Go to <routineName>" from the pop-up menu.
- 3) Exit the debugger by clicking the "Go" button or by pressing Escape.

Now the selected routine will be visible in the top procedure window, where you can edit it.

Debugger Shortcuts

Action	Shortcut
To enable debugger	Choose Enable Debugger from the Procedure menu or choose Enable Debugger from the procedure window's pop-up menu after Control-clicking (<i>Macintosh</i>) or right-clicking (<i>Windows</i>).
To automatically enter the debugger when an error occurs	Choose Debug on Error from the Procedure menu or choose Enable Debugger from a procedure window's pop-up menu after Control-clicking (<i>Macintosh</i>) or right-clicking (<i>Windows</i>).
To set or clear a breakpoint	Click in the left margin of the procedure window or click anywhere on the procedure window line where you want to set or clear the breakpoint and choose Set Breakpoint or Clear Breakpoint from a procedure window's pop-up menu after Control-clicking (<i>Macintosh</i>) or right-clicking (<i>Windows</i>).
To enable or disable a breakpoint	Shift-click a breakpoint in the left margin of the procedure window. Click anywhere on the procedure window line where you want to enable or disable the breakpoint and choose Enable Breakpoint or Disable Breakpoint procedure window's pop-up menu after Control-clicking (<i>Macintosh</i>) or right-clicking (<i>Windows</i>).
To execute the next command	On <i>Macintosh</i> press Enter, keypad Enter, or Return. For <i>Windows</i> , if no button has the focus, press Enter or Return. Otherwise, click the yellow arrow button.
To step into a subroutine	Press the +, =, or keypad + keys, or click the blue descending arrow button.
To step out of a subroutine to the calling routine	Press the -, _ (underscore) or keypad - keys, or click the blue ascending arrow button.
To resume executing normally	Press Escape (Esc), or click the green arrow button.
To cancel execution	Click the red stop sign button.
To edit the value of a macro or function variable	Double-click the second column of the variables list, edit the value, and press Return or Enter.
To set the value of a function's string to null	Double-click the second column of the variables list, type "<null>" (without the quotes), and press Return or Enter.
To view the current value of a macro or function variable	Move the cursor to the procedure text of the variable name and wait. On <i>Macintosh</i> , the value appears to the right of the debugger buttons. On <i>Windows</i> , the value appears in a tooltip window.

Action	Shortcut
To view the current value of an expression	Select the expression text with the cursor, position the cursor over the selection, and wait. (Expressions involving user-defined functions will not be evaluated unless V_debugDangerously is set to 1.)
To view global values in the current data folder	Choose “local and global variables” from the debugger pop-up menu.
To view type information about variables	Choose “show variable types” from the debugger pop-up menu.
To resize the columns in the variables list	Drag a divider in the list to the left or right.
To show or hide the Waves, Structs, and Expressions pane	Drag the divider on the right side of the Variables list left or right.

Programming with Dependencies.....	174
Using Operations in Dependency Formulas.....	175
Dependency Caveats	175

Dependency Formulas

Igor Pro supports “dependent objects”. A dependent object can be a wave, a global numeric variable or a global string variable that has been linked to an expression. The expression to which an object is linked is called the object’s “dependency formula” or “formula” for short.

The value of a dependent object is updated whenever any other global object involved in the formula is modified (even if its value stays the same). We say that the dependent object *depends* on these other global objects *through* the formula.

You might expect that an assignment such as:

```
wave1 = sin(K0*x/16)
```

meant that wave1 would be updated whenever K0 changed. It doesn’t; values are computed for wave1 only once, and the relationship between wave1 and K0 is forgotten.

However, if the = in the above assignment is replaced with :=

```
wave1 := sin(K0*x/16)
```

then Igor *does* create just such a dependency. Now whenever K0 changes, the contents of wave1 will be updated. In this example, wave1 is a dependent object. It depends on K0, and $\sin(K0 \cdot x / 16)$ is wave1’s dependency formula.

You can also establish a dependency using the SetFormula operation, like this:

```
SetFormula wave1, "sin(K0*x/16)"
```

Wave1 depends on K0 because K0 is a changeable variable. Wave1 *also* depends on the function x (x is not a variable) that returns the X scaling of the destination wave (wave1). When the X scaling of wave1 changes, the values that the x function returns change, so this dependency assignment is reevaluated. The remaining terms (sin and 16) are not changeable, so wave1 does not depend on them.

Like other assignment statements, the data folder context for the right-hand side is that of the destination object. Therefore, in the following example, wave2 and var1 must be in the data folder named foo, var2 must be in root and var3 must be in root:bar.

```
root:foo:wave1 := wave2*var1 + ::var2 + root:bar:var3
```

Data Folders are described in Chapter II-8, **Data Folders**.

A dependency assignment is often used in conjunction with SetVariable controls (see page III-348) and Value Display controls (see page III-349).

Here’s a simple example. Execute these commands on the command line:

```
K0=1
Make/O wave1:=sin(K0*x/16)
Display /W=(4,53,399,261) wave1
ControlBar 23
SetVariable setvar0,size={60,15},value=K0
```

This results in the following graph:

Click here to change the value of $K0$.

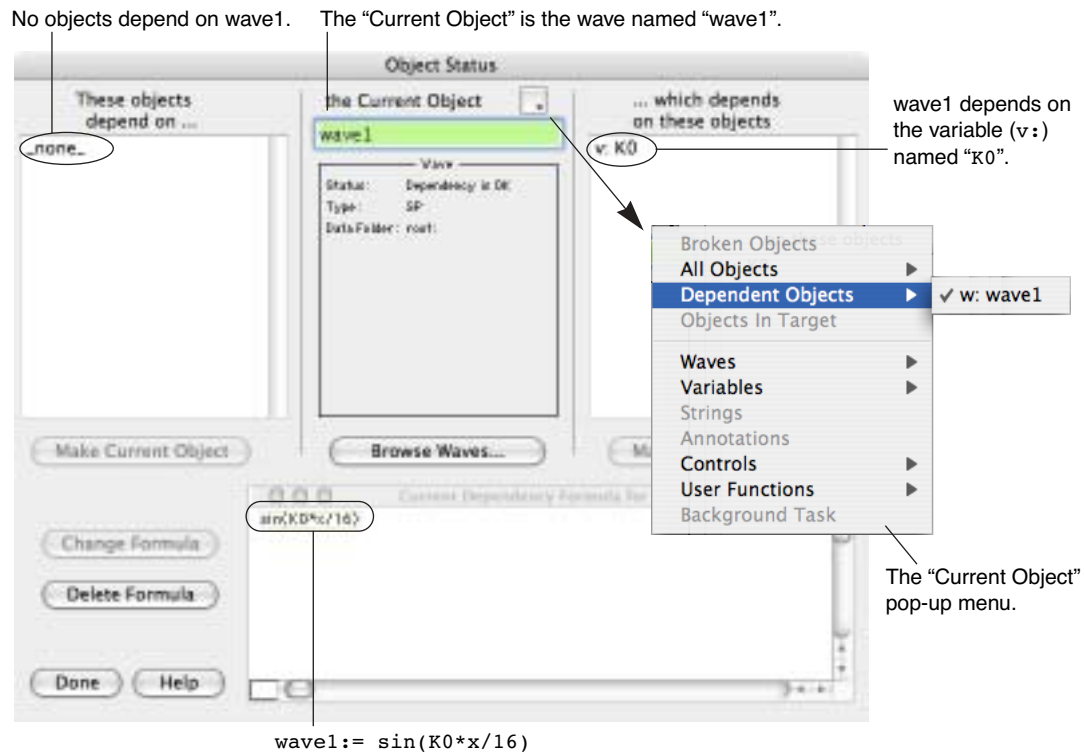

This period changes when $K0$ changes, because
 $\text{wave1} := \sin(K0/16)$.

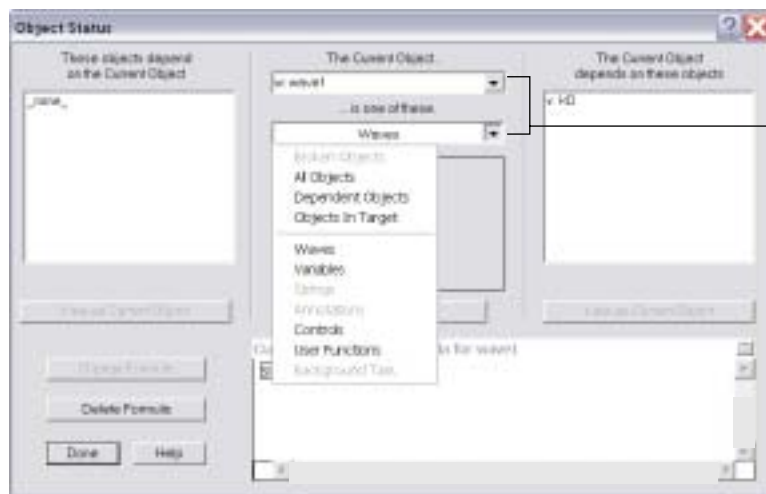

Click the SetVariable control's up and down arrows to adjust $K0$ and observe that wave1 is automatically updated.

Dependencies and the Object Status Dialog

You can use the Object Status dialog in the Misc menu to check dependencies. On the Macintosh, all dependent objects are listed in the Current Object pop-up menu under Dependent Objects:

The Windows version of the Object Status dialog is essentially the same but for a slightly different arrangement of the pop-up menus:

Windows dialog pop-up menus for individually selecting the object and type of object.

The Status field in the box below the current object name indicates any dependency status:

- “No dependency” means that the current object does not depend on anything.
- “Dependency is OK” means that the dependency formula successfully updated the current object.
- “Update failed” means that the dependency formula used to compute the current object’s value failed, probably because there is a syntax error in the formula or one of the objects referenced in the formula does not exist or has been renamed. If an update fails, then the objects that depend on that update are broken and they appear in the Broken Objects submenu. See **Broken Dependent Objects** on page IV-174.

You can create a new dependency formula with the New Formula button, delete one with the Delete Formula button, change an existing one by typing in the Dependency Formula window and clicking the Change Formula button, and undo that change by clicking the Restore Formula button.

This is discussed further in **The Object Status Dialog** on page III-401.

You can also read the text of a dependency formula with the string function `GetFormula`, and set it with the operation `SetFormula`.

Numeric and String Variable Dependencies

Dependencies can also be created for global (but not local) user-defined numeric and string variables. Here is a user-defined function that creates a dependency (the global variable `recalculateThis` will depend on another global variable `dependsOnThis`):

```
Function TestRecalculation()  
    Variable/G recalculateThis  
    Variable/G dependsOnThis= 1  
  
    // Create dependency on global variable  
    SetFormula recalculateThis, "dependsOnThis"  
  
    Print recalculateThis          // Prints original value  
  
    dependsOnThis = 2              // Changes something recalculateThis  
  
    DoUpdate                       // Make Igor recalculate formulae  
  
    Print recalculateThis          // Prints updated value  
End
```

Running this function prints the following to the history area:

```
•TestRecalculation()  
  1  
  2
```

The call to DoUpdate is needed because Igor recalculates dependency formulas only when no user-defined functions are running or when DoUpdate is called.

This function uses SetFormula to create the dependency because the := operator is not allowed in user-defined functions.

Note: You can not create a dependency *for* system numeric variables K0...K19 or veclen. You can create a dependency for something else *on* those variables, as in the first example of this chapter. In general, it is actually best if you do *not* use system variables in dependencies, since they are involved in Curve Fitting. You should define your own global variables for use in dependencies.

Wave Dependencies

The assignment statement:

```
dependentWaveName := formula
```

creates a dependency and links the dependency formula to the dependent wave. Whenever any change is made to any object in the formula, the contents of the dependent wave are updated.

The command

```
SetFormula dependentWaveName, "formula"
```

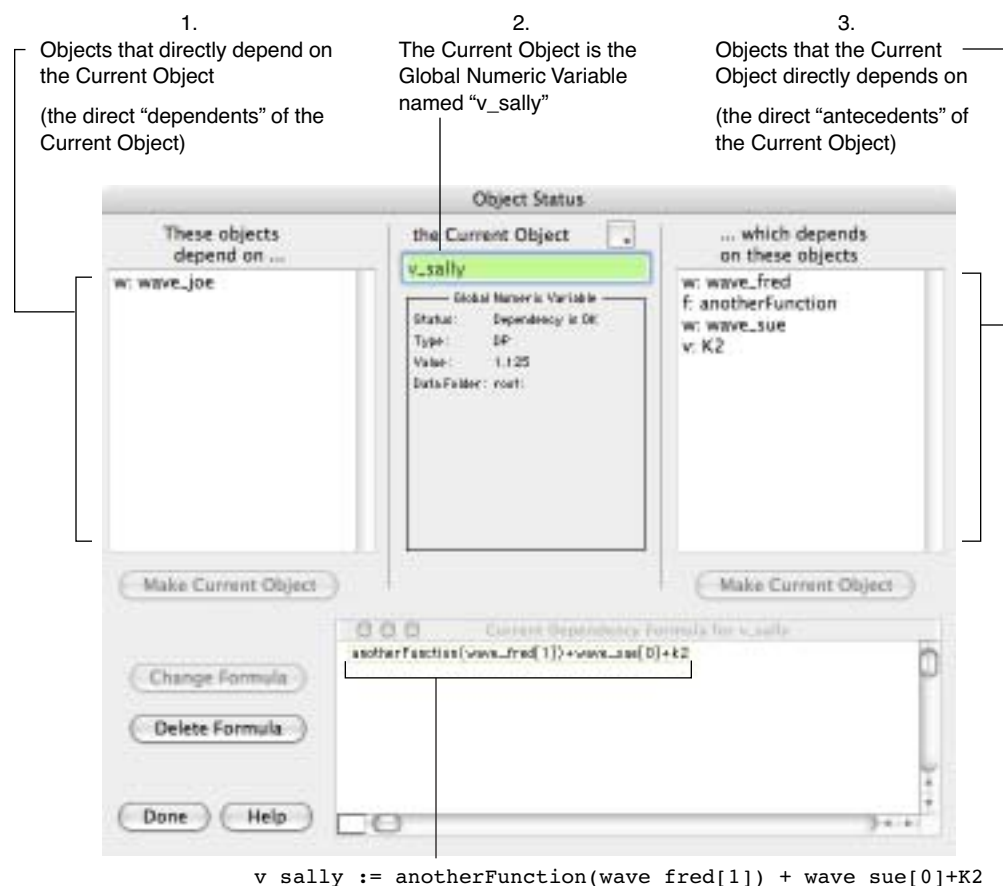

establishes the same dependency.

Cascading Dependencies

“Cascading dependencies” refers to the situation that arises when an object depends on a second object, which in turn depends on a third object, etc. When an object changes, all objects that directly depend on that object are updated, *and* objects that depend directly on those updated objects are updated until no more updates are needed.

The Object Status dialog shows three levels of dependency anchored on the Current Object:

Chapter IV-9 — Dependencies

In this example, the current object is the global numeric variable `v_sally`. The only object directly dependent on `v_sally` is the wave `wave_joe`. `v_sally` directly depends on waves `wave_fred` and `wave_sue`, global numeric variable `K2`, and user-defined function `anotherFunction`. These dependencies exist because of the dependency assignment:

```
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
```

which can be changed or deleted with the dialog.

`Wave_joe` depends on `v_sally` for reasons that will become apparent only when `wave_joe` is made the current object:

The dependency was created by the dependency assignment:

```
wave_joe := v_sally + wave_fred[0] + myFunction(x)
```

Combining the dependency of wave_joe on v_sally with what v_sally depends on, you can see that wave_joe also *indirectly* depends on wave_sue, wave_fred, K2, and anotherFunction:

If you change K2, the dependencies will cascade so that v_sally and then wave_joe are updated. We call objects that wave_joe depends on directly or indirectly its “antecedents” (literally, “those that go before”).

Deleting a Dependency

A dependency is deleted when the dependent object is assigned a value using the = operator:

```
recalculateThis := dependsOnThis    // creates dependency
recalculateThis = 0                  // deletes the dependency
```

This method of deleting a dependency does not work in user-defined functions. You must use the SetFormula operation.

For example:

```
Execute "recalculateThis = 0"
```

will delete the dependency even in a user-defined function.

You can also delete this dependency using the SetFormula operation.

```
SetFormula recalculateThis, ""
```

Wave dependencies are also deleted by operations that overwrite the values of their wave parameters. Some of these operations are:

Chapter IV-9 — Dependencies

FFT Convolve Correlate Smooth GraphWaveEdit
Hanning Differentiate Integrate UnWrap

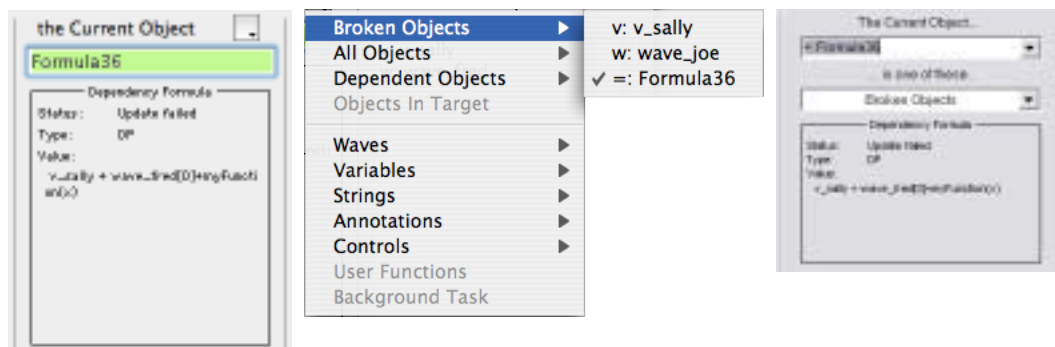

Dependencies can also be deleted via the Object Status dialog in the Misc menu.

Broken Dependent Objects

Igor compiles the text of a dependency formula to low-level code and stores both the original text and the low-level code with the dependent object. At various times, Igor may need to recompile the dependency formula text. At that time it is possible to get a compilation error if one of the objects in the formula has been renamed or deleted, or if the formula contains a syntax error.

When this happens, the dependent object will no longer update but will retain its last value. We call such an object “broken”. If you suspect this kind of problem has happened, invoke the Object Status dialog using the Misc menu.

Any such broken objects will show up in the Broken Objects submenu of the Current Object pop-up menu:

When Dependencies are Updated

Dependency updates take place at the same time that graphs are updated. This happens after each line in a macro is executed, or when DoUpdate is called from a macro or user function, or continuously if a macro or function is not running.

Dependency formulas used as input to the SetBackground and ValDisplay operations, and in some other contexts, can alternately be specified as a literal string of characters using the following syntax:

```
#"text_of_the_dependency_expression"
```

Note that what follows the # char must be a literal string — not a string expression.

This will set the dependency formula *without* compiling it or checking it for validity. It is mainly for use internally but if you find yourself in a situation where you need to set the dependency formula of an object to something that is not currently valid but will be in the future then feel free to use this alternate method.

Programming with Dependencies

You cannot use := to create dependencies in user-defined functions. Instead you must use the **SetFormula** operation (see page V-495).

```
Function TestFunc()  
    Variable/G varNum=-666  
    Make wave1  
    SetFormula wave1, "varNum"      // Equivalent to wave1 := varNum  
End
```

Using Operations in Dependency Formulas

The dependency formula must be a single expression — and you can not use operations, such as FFT's, or other command type operations. However, you can invoke user-defined functions which *in turn* invoke operations:

```
Function MakeDependencyUsingOperation()
    Make/O/N=128 data = p          // A ramp from 0 to 127
    Variable/G power

    SetFormula power, "RMS(data)" // Dependency on function and wave
    Print power

    data = p * 2                  // Changes something power depends
    DoUpdate                     // Make Igor recalc formulae
    Print power
EndMacro

Function RMS(w)
    Wave w

    WaveStats/Q w                // An operation! One output is V_rms
    return V_rms
End
```

When MakeDependencyUsingOperation is executed, it prints the following in the history area:

```
•MakeDependencyUsingOperation()
  73.4677
  146.935
```

Dependency Caveats

The extensive use of dependencies can create a confusing tangle that can be difficult to manage. Although you can use the Object Status dialog to explore the dependency hierarchy, you can still become very confused very quickly, especially when the dependencies are highly cascaded. You should use dependencies only where they are needed. Use conventional assignments for the majority of your calculations.

There is no built-in limit to the depth of dependency cascading except that speed considerations will limit the depth to about 20. Similarly there will be a practical limit to the total number of objects with dependencies. The actual limit can not be specified in advance.

Dependency formulas are generally not recalculated when a user-defined function is running unless you explicitly call the DoUpdate operation. However, they can run at other hard to predict times (especially on Windows) and you should not make any assumptions as to the timing or the current data folder when they run.

The text of the dependency formula that is saved for a dependent object is the original literal text. The dependency formula needs to be recompiled from time to time, for example when procedures are compiled. Therefore, any objects used in the formula must persist until the formula is deleted.

We recommend that you never use \$ expressions in a dependency formula.

This chapter contains usage notes on a number of advanced programming topics.

Sound

Two operations are provided for playing of sound through the computer speakers:

- PlaySound
- PlaySnd (*Macintosh*)

The PlaySound operation takes the sound data from a wave while the PlaySnd operation gets its data from a Macintosh 'snd' resource stored in a file. PlaySnd is useful for playing prerecorded sounds while PlaySound is useful for playing sounds that you create or modify.

Refer to Chapter V-1, **Igor Reference**, for details on PlaySound and PlaySnd.

A number of sound input operations are provided: **SoundInStatus** (page V-523), **SoundInSet** (page V-522), **SoundInRecord** (page V-521), **SoundInStartChart** (page V-522) and **SoundInStopChart** (page V-523). Several example experiments that use these routines can be found in your Igor Pro Folder in the Examples folder.

A Macintosh XOP, called SndLoadSaveWave, loads and saves various sound file formats. On Windows, the LoadWavFile XOP performs similar functions. See the More Extensions:File Loaders folder for details.

Movies

If you have Apple's QuickTime installed on your computer, you can create or play movies. You can even add a soundtrack to your movies.

The process of creating a movie is very simple. You use the following operations to create a new movie file, add video frames and audio, close the file and then play the movie. Refer to Chapter V-1, **Igor Reference**, for details on the operations.

- NewMovie
- AddMovieFrame
- AddMovieAudio
- CloseMovie
- PlayMovie
- PlayMovieAction

The NewMovie operation creates a movie file and also defines the movie frame rate and optional audio track specifications. Before calling NewMovie, you need to prepare the first frame of your movie as the target graph. If you will be using audio you also need to prepare a sound wave. The sound wave can be of any time duration but usually will either be the entire length of the movie or will be the length of one video frame. If you will be placing your movie on a Web page or transferring it across platforms, be sure to use the /L flag with NewMovie to create a "flattened" movie.

After creating the file and the first video frame and optional audio, you use AddMovieFrame to add as many video frames as you wish. You may also add more audio using the AddMovieAudio operation. Finally you use the CloseMovie and PlayMovie operations.

When you write a procedure to generate a movie, you need to call the DoUpdate operation after all modifications to the graph and before calling AddMovieFrame. This allows Igor to process any changes you have made to the graph.

You may use the PlayMovie operation to play any QuickTime movie — not just those you create with Igor.

You can extract individual frames from a movie and can control movie playback using PlayMovieAction.

For examples of programming with movies, see the Examples:Movies & Audio folder.

Timing

There are two methods you can use when you want to measure elapsed time:

- The ticks counter using the ticks function
- The microsecond timer using StartMSTimer() and StopMSTimer()

Ticks Counter

You can easily measure elapsed time with a precision of 1/60th of a second using the ticks function. It returns the tick count which starts at zero when you first start your computer and is incremented at a rate of approximately 60 Hz rate from then on.

Here is an example of typical use:

```
...
Variable t0
...
t0= ticks
<operations you wish to time>
printf "Elapsed time was %g seconds\r", (ticks-t0)/60
...
```

Microsecond Timer

You can measure elapsed time to microsecond accuracy for durations up to 35 minutes using the microsecond timer. See the `startMSTimer` function (page V-533) for details and an example.

Saving Package Preferences

If you are writing a sophisticated package of Igor procedures you may want to save preferences for your package. For example, if your package creates a control panel that can be opened in any experiment, you may want it to remember its position on screen between invocations. Or you may want to remember various settings in the panel from one invocation to the next.

Such “state” information can be stored either separately in each experiment or it can be stored just once for all experiments in preferences. These two approaches both have their place, depending on circumstances. But if your package creates a control panel that is intended to be present at all times and used in any experiment then the preferences approach is usually the best fit.

If you choose the preferences approach, you will store your package preference file in a directory created for your package. Your package directory will be in the Packages directory, inside Igor’s own preferences directory.

The location of Igor’s Packages directory depends on the operating system and the particular user’s configuration. You can find where it is on a particular system by executing:

```
Print SpecialDirPath("Packages", 0, 0, 0)
```

Important: You must choose a very distinctive name for your package because that is the only thing that prevents some other package from overwriting yours. All package names starting with “WM” are reserved for WaveMetrics.

A package name is limited to 31 characters and must be a legal name for a directory on disk.

There are two ways to store package preference data:

In a special-format binary file stored in your package directory.

As Igor waves and variables in an Igor experiment file stored in your package directory.

The special-format binary file approach is relatively simple to implement but is not suitable for storing very large amounts of data. In most cases it is not necessary to store very large amounts of data so this is the way to go.

The use of the Igor experiment file supports storing a large amount of preference data but creates a problem of synchronizing your preference data stored in memory and your preference data stored on disk. It also leads to a proliferation of preference data stored in various experiments. You should avoid using this technique if possible.

Saving Package Preferences in a Special-Format Binary File

This approach supports preference data consisting of a collection of numeric and string data. You define a structure encapsulating your package preference data. You use the **LoadPackagePreferences** operation (page V-308) to load your data from disk and the **SavePackagePreferences** operation (page V-480) to save it to disk.

The LoadPackagePreferences and SavePackagePreferences were added in Igor Pro 5.04B07 so if you use this technique, your package will require that version or later.

SavePackagePreferences stores data from your package's preferences data structure in memory. LoadPackagePreferences returns that data to you via the same structure.

SavePackagePreferences also creates a directory for your package preferences and stores your data in a file in that directory. Your package directory is located in the Packages directory in Igor's preferences directory. The job of storing the preferences data in the file is handled transparently which, by default, automatically flushes your data to the file when the current experiment is saved or closed and when Igor quits.

You would call LoadPackagePreferences every time you need to access your package preference data and SavePackagePreferences every time you want to change your package preference data. You pass to these operations an instance of a structure that you define.

Here are example functions that use the LoadPackagePreferences and SavePackagePreferences operations to implement preferences for a particular package:

```
// NOTE: The name you choose must be distinctive!
static StrConstant kPackageName = "Acme Data Acquisition"
static StrConstant kPreferencesFileName = "PanelPreferences.bin"
static Constant kPreferencesRecordID = 0

Structure AcmeDataAcqPrefs
    uint32 version // Preferences structure version number. 100 means 1.00.
    double panelCoords[4] // left, top, right, bottom
    uchar phaseLock
    uchar triggerMode
    double ampGain
    uint32 reserved[100] // Reserved for future use
EndStructure

Function AcmeDataAcqLoadPackagePrefs(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    Variable currentPrefsVersion = 100

    // This loads preferences from disk if they exist on disk.
    LoadPackagePreferences kPackageName, kPreferencesFileName, kPreferencesRecordID, prefs

    // If error, prefs not found or not compatible, initialize them.
    if (V_flag!=0 || V_bytesRead==0 || prefs.version!=currentPrefsVersion)
        prefs.version = currentPrefsVersion

        prefs.panelCoords[0] = 5 // Left
        prefs.panelCoords[1] = 40 // Top
        prefs.panelCoords[2] = 300 // Right
        prefs.panelCoords[3] = 250 // Bottom
        prefs.phaseLock = 1
        prefs.triggerMode = 1
        prefs.ampGain = 1.0

        Variable i
        for(i=0; i<100; i+=1)
            prefs.reserved[i] = 0
        endfor

        AcmeDataAcqSavePackagePrefs(prefs) // Create default prefs file.
    endif
End
```

Chapter IV-10 — Advanced Programming

```
Function AcmeDataAcqSavePackagePrefs(prefs)
    STRUCT AcmeDataAcqPrefs &prefs

    SavePackagePreferences kPackageName, kPreferencesFileName, kPreferencesRecordID, prefs
End
```

The package preferences structure, `AcmeDataAcqPrefs` in this case, must not use fields of type `Variable`, `String`, `WAVE`, `NVAR`, `SVAR` or `FUNCREF` because these fields refer to data that may not exist when `LoadPackagePreferences` is called. It can use fields of type `char`, `uchar`, `int16`, `uint16`, `int32`, `uint32`, `float` and `double` as well as fixed-size arrays of these types and substructures with fields of these types.

Use the reserved field to add fields to the structure in a backward-compatible fashion. For example, a subsequent version of the structure might look like this:

```
Structure AcmeDataAcqPrefs
    uint32    // Preferences structure version number. 100 means 1.00.
    double panelCoords[4]    // left, top, right, bottom
    uchar phaseLock
    uchar triggerMode
    double ampGain
    uint32 triggerDelay
    uint32 reserved[99]    // Reserved for future use
EndStructure
```

Here the `triggerDelay` field was added and size of the reserved field was reduced to keep the overall size of the structure the same. The `AcmeDataAcqLoadPackagePrefs` function would also need to be changed to set the default value of the `triggerDelay` field.

If you need to change the structure such that its size changes or its fields are changed in an incompatible manner then you must change your structure version, which will overwrite old preferences with new preferences.

A functioning example using this technique can be found in:

“Igor Pro Folder:Examples:Programming:Package Preferences Demo.pxp”

In the example above we store just one structure in the preference file. However `LoadPackagePreferences` and `SavePackagePreferences` allow storing any number of structures of the same or different types in the preference file. You can store either multiple instances of the same structure or multiple different structures. You must assign a unique nonnegative integer as a record ID for each structure stored and pass this record ID to `LoadPackagePreferences` and `SavePackagePreferences`. You could use this feature, for example, to store a different structure for each type of control panel that your package presents. Since all data is cached in memory you should not attempt to store hundreds or thousands of structures.

In almost all cases a particular package will need just one preference file. For the rare cases where this is inconvenient, `LoadPackagePreferences` and `SavePackagePreferences` allow each package to create any number of preference files, each with a distinct file name. All of the preference files for a particular package are stored in the same directory, the package’s preferences directory. Each file can store a different set of structure. However, the code that implements this feature is not tuned to handle large numbers of files so you should not use this feature indiscriminately.

Saving Package Preferences in an Experiment File

This approach supports package preference data consisting of waves, numeric variables and string variables. It is more difficult to implement than the special-format binary file approach and is not recommended except for expert programmers and then only if the previously described approach is not suitable.

You use the `SaveData` operation to store your waves and variables in a packed experiment file in your package directory on disk. You can later use the `LoadData` operation to load the waves and variables into a new experiment.

You must create your package directory as illustrated by the `SavePackagePrefs` function below.

The following example functions save and load package preferences. These functions assume that the package preferences consist of all waves and variables at the top level of the package's data folder. You may need to customize these functions for your situation.

```
// SavePackagePrefs(packageName)
// Saves the top-level waves, numeric variables and string variables
// from the data folder for the named package into a file in the Igor
// preferences hierarchy on disk.
Function SavePackagePrefs(packageName)
    String packageName // NOTE: Use a distinctive package name.

    // Get path to Packages preferences directory on disk.
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName

    // Create a directory in the Packages directory for this package
    NewPath/O/C/Q tempPackagePrefsPath, fullPath

    fullPath += ":Preferences.pxp"

    String saveDF = GetDataFolder(1)
    SetDataFolder root:Packages:$packageName
    SaveData/O/Q fullPath // Save the preference file
    SetDataFolder saveDF

    // Kill symbolic path but leave directory on disk.
    KillPath/Z tempPackagePrefsPath
End

// LoadPackagePrefs(packageName)
// Loads the data from the previously-saved package preference file,
// if it exist, into the package's data folder.
// Returns 0 if the preference file existed, -1 if it did not exist.
// In either case, this function creates the package's data folder if it
// does not already exist.
// LoadPackagePrefs does not affect any other data already in the
// package's data folder.
Function LoadPackagePrefs(packageName)
    String packageName // NOTE: Use a distinctive package name.

    Variable result = -1
    String saveDF = GetDataFolder(1)

    NewDataFolder/O/S root:Packages // Ensure root:Packages exists
    NewDataFolder/O/S $packageName // Ensure package data folder exists

    // Find the disk directory in the Packages directory for this package
    String fullPath = SpecialDirPath("Packages", 0, 0, 0)
    fullPath += packageName
    GetFileFolderInfo/Q/Z fullPath
    if (V_Flag == 0) // Disk directory exists?
        fullPath += ":Preferences.pxp"
        GetFileFolderInfo/Q/Z fullPath
        if (V_Flag == 0) // Preference file exist?
            LoadData/O/R/Q fullPath // Load the preference file.
            result = 0
        endif
    endif

    SetDataFolder saveDF
    return result
End
```

The hard part of using the experiment file for saving package preferences is not in saving or loading the package preference data but in choosing when to save and load it so that the latest preferences are always used. There is no ideal solution to this problem but here is one strategy:

1. When package preference data is needed (e.g., you are about to create your control panel and need to know the preferred coordinates), check if it exists in memory. If not load it from disk.
2. When the user does a New Experiment or quits Igor, if package preference data exists in memory, save it to disk. This requires that you create an IgorNewExperimentHook function and an IgorQuitHook function.
3. When the user opens an experiment file, if it contains package preference data, delete it and reload from disk. This requires that you create an AfterFileOpenHook function. This is necessary because

the package preference data in the just opened experiment is likely to be older than the data in the package preference file.

Creating Formatted Text

The `printf`, `sprintf`, and `fprintf` operations print formatted text to Igor's history area, to a string variable or to a file respectively. The `wfprintf` operation prints formatted text based on data in waves to a file.

All of these operations are based on the C `printf` function which prints the contents of a variable number of string and numeric variables based on the contents of a format string. The format string can contain literal text and conversion specifications. Conversion specifications define how a variable is to be printed.

Here is a simple example:

```
printf "The minimum is %g and the maximum is %g\r", V_min, V_max
```

In this example, the format string is "The minimum is %g and the maximum is %g\r" which contains some literal text along with two conversion specifications — both of which are "%g" — and an escape code ("\r") indicating "carriage-return". If we assume that the Igor variable `V_min` = .123 and `V_max` = .567, this would print the following to Igor's history area:

```
The minimum is .123 and the maximum is .567
```

We could print this output to an Igor string variable or to a file instead of to the history using the `sprintf` (see page V-529) or `fprintf` (see page V-165) operations.

Printf Operation

The syntax of the `printf` operation is:

```
printf format [, parameter [, parameter ] . . .]
```

where *format* is the format string containing literal text or format specifications. The number and type of parameters depends on the number and type of format specifications in the format string. The parameters, if any, can be literal numbers, numeric variables, numeric expressions, literal strings, string variables or string expressions.

The conversion specifications are very flexible and make `printf` a powerful tool. They can also be quite involved. The simplest specifications are:

Specification	What It Does
%g	Converts a number to text using integer, floating point or exponential notation depending on the number's magnitude.
%e	Converts a number to text using exponential notation.
%f	Converts a number to text using floating point notation.
%d	Converts a number to text using integer notation.
%s	Converts a string to text.

Here are some examples:

```
printf "%g, %g, %g\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.14159, 6.022e+23, 1.602e-19
```

```
printf "%e, %e, %e\r", PI, 6.022e23, 1.602e-19
```

prints:

```
3.141593e+00, 6.022000e+23, 1.602000e-19
```

```
printf "%f, %f, %f\r", PI, 6.022e23, 1.602e-19
```

This generates a comma delimited file. To generate a tab delimited file, use:

```
fprintf f1, "wave1\twave2\twave3\r"
wfprintf f1, "%g\t%g\t%g\r" wave1, wave2, wave3
```

Since tab-delimited is the default format for `wfprintf`, this last command is equivalent to:

```
wfprintf f1, "" wave1, wave2, wave3
```

Client/Server Overview

Igor Pro can act as a server — accepting commands and data from a client program and returning results, as a client — sending commands and data to a server program, or as both at the same time.

For the Macintosh, see **Apple Events** on page IV-186 for server information and **AppleScript** on page IV-188 for client capabilities. Previous versions of Igor supported an Apple technology called Program-to-Program Communication (PPC). Apple's operating systems no longer support PPC so it is no longer supported in Igor.

For Windows, see **ActiveX Automation** on page IV-189. Igor can play the role of an Automation server but not an Automation client. However it is possible to generate script files that allow Igor to indirectly play the role of client.

On Windows, Igor also supports Dynamic Data Exchange (DDE) and can be a DDE server or DDE client. Because DDE is obsolescent and being phased out by Microsoft, new programming should use ActiveX automation. Igor's support for DDE is described in the Obsolete Topics help file.

Apple Events

This topic is of interest to *Macintosh* programmers. Windows users should see the section for **ActiveX Automation** on page IV-189.

This topic contains information for Igor users who wish to control Igor from other programs (e.g., AppleScript). It also contains information useful to people who are writing their own programs and wish to use Igor Pro as a compute/graphing engine.

There is also a mechanism that allows Igor to act like a controller and initiate Apple event communication with other programs. See **AppleScript** on page IV-188.

It is assumed that the reader of this material is an experienced Igor user.

Apple Event Capabilities

Igor Pro supports the following Apple events:

The four required events:

Open Application	Basically a nop; don't use.
Open Document	Loads an experiment.
Print Document	NA; don't use.
Quit Application	Quits.

Some core events:

Close	Acts on experiment, window or PPC port.
Save	Acts on experiment only.
Open	NA; don't use.

From the misc standard suite:

Do Script	Executes commands; can return ASCII results.
Eval Expression	Same as Do Script; obsolete but included for compatibility.

Apple Events — Basic Scenario

You use the Open Document event to cause Igor to load an experiment with whatever goodies you find useful (macros, useful waves and variables or whatever). You then use the Do Script or Eval Expression events to send commands to Igor for execution and to retrieve results. To get data into Igor you write files and then send commands to Igor to load the data. To get data waves from Igor you do the reverse. To get PICT data you send commands to Igor that cause it to write a PICT file that you can read. You may then close the experiment and start over with a new one. You will not likely use the Save event.

Apple Events — Obtaining Results from Igor

To return information from Igor, you will need to embed special commands in the script you send to Igor for execution. When Igor encounters these commands, it appends results to a packet that is returned to your application after script execution ends. The special commands are variations on the standard Igor commands FBinWrite and fprintf. Both of these commands take a file reference number as a parameter. If the magic value zero is used rather than a real file reference number, then the data that would normally be written to a file is appended to the result packet.

As far as Igor is concerned, there is no difference between the Do Script and Eval Expression events. However, old applications may expect results from Eval Expression and not from Do Script.

To use waves and PICTs with Apple events, you will need to write or read the data via standard Igor files. For example, you might include

```
SavePICT/P=myPath as "a PICT file"
```

in a script that you send to Igor for execution. You could then read the file in your application.

Apple Event Details

This information is intended for programmers familiar with Apple events terminology.

Some of the following events can act on experiments or windows.

To specify an experiment, use object class cDocument ('docu') and specify either formAbsolutePosition with index=1 or formName with name=*name of experiment*.

To specify a window, use object class cWindow ('cwin') and either formAbsolutePosition or formName with name=*title of window*.

Open Application Event class: 'aevt' Event: 'oapp'

Basically a nop; don't use.

Open Document Event class: 'aevt' Event: 'odoc'

Loads an experiment. Direct object is assumed to be coercible to a File System Spec record.

Print Document Event class: 'aevt' Event: 'pdoc'

NA; don't use.

Quit Application Event class: 'aevt' Event: 'quit'

Quits the program. If the experiment was modified, then Igor attempts to interact with the user to get save/no save directions. If interaction is not allowed, then an error is returned and nothing is done. To prevent errors, send the close event with appropriate save options prior to sending quit.

Close Event class: 'core' Event: 'clos'

Acts on an experiment or window.

For a window, the save/no save/ask optional parameter (keyAESaveOptions) is allowed and refers to making/replacing a recreation macro.

For a document (experiment), keyAESaveOptions is allowed and an additional optional parameter keyAEDestination may be used to specify where to save (must be coercible to a FSS). If this is not given and the experiment is untitled and if an attempt to interact with the user fails then the exper-

iment is not saved and an error (such as `errAENoUserInteraction`) is returned. Note that if the optional destination is given then the save options are ignored (why give a destination and then say no save?).

Save Event class: 'core' Event: 'save'

Acts on experiment only.

Takes same optional destination parameters as Close. A save with a destination is the same as a Save as.

Do Script Event class: 'misc' Event: 'dosc'

Same as Eval Expression.

Eval Expression Event class: 'aevt' Event: 'eval'

Executes commands. Acts just as if commands had been typed into the command line except the individual command lines are preceded by a “¶” symbol rather than the usual “•” symbol. Also, errors are returned in the error reply parameter of the event rather than putting up a dialog.

Note: You can suppress history logging by executing the command, “Silent 2”, and you can turn it back on by executing “Silent 3”.

Direct parameter must be text and not a file. Text can be of any length.

You can return a string containing results by using the `fprintf` command with a file reference number of zero.

AppleScript

This topic is of interest to *Macintosh* programmers. Windows users should see the section for **ActiveX Automation** on page IV-189.

Igor supports the creation and execution of simple AppleScripts in order to send commands to other programs.

To execute an AppleScript program, you first compose it in a string and then pass it to the `ExecuteScriptText` operation, which in turn passes the text to Apple’s scripting module for compilation and execution. The result (which might be an error message) is placed in a string variable named `S_value`. Igor does not save the compiled script so every time you call `ExecuteScriptText` your script will have to be recompiled. See the **ExecuteScriptText** operation on page V-131 for additional details.

The documentation for the **ExecuteScriptText** operation (page V-131) includes an example that shows how to execute a Unix command.

Because there is no easy way to edit a script or to see where errors occur, you should first test your script using Apple’s Script Editor application.

You can use “Silent 2” to prevent commands your script sends to Igor from being placed in the history area.

You can send commands to Igor without using the `tell` keyword.

You should check your quoting carefully. Your text must be quoted both for Igor and for Apple’s scripting system. For example,

```
ExecuteScriptText "Do Script \"Print \\\"hello\\\"\""
```

You should compose scripts in string variables one line at a time to improve readability.

If an error occurs that you can’t figure out, print the string, copy from the history and paste into a Script Editor for debugging.

If the script returns a text return value, it will be quoted within the `S_value` string.

Don’t forget to include the carriage return escape code, `\r`, at the end of each line of a multiline script.

The first time you call this routine, it may take an extra long time while the Mac OS loads the scripting modules.

Executing Unix Commands on Mac OS X

On Mac OS X, you can use AppleScript to send a command to the Unix shell. Here is a function that illustrates this:

```
Function/S ExecuteUnixShellCommand(uCommand, printCommandInHistory, printResultInHistory)
    String uCommand                // Unix command to execute
    Variable printCommandInHistory
    Variable printResultInHistory

    if (printCommandInHistory)
        printf "Unix command: %s\r", uCommand
    endif

    String cmd
    sprintf cmd, "do shell script \"%s\"", uCommand
    ExecuteScriptText cmd

    if (printResultInHistory)
        Print S_value
    endif

    return S_value
End
```

You can test the function with this command:

```
ExecuteUnixShellCommand("ls", 1, 1)
```

Life is a bit more complicated if the command that you want to execute contains spaces or other nonstandard Unix command characters. For example, imagine that you want to execute this:

```
ls /System/Library/Image Capture
```

These commands will not work because of the space in the command:

```
String unixCmd = "ls /System/Library/Image Capture"
ExecuteUnixShellCommand("ls", 1, 1)
```

You need to quote the entire Unix command. In order to do this such that the quotes will make it through Igor's parser and AppleScript's parser, you must do this:

```
String unixCmd = "ls \\""/System/Library/Image Capture\\"\""
ExecuteUnixShellCommand("ls", 1, 1)
```

Igor's parser converts `\\` to `\` and `\` to `"`, so AppleScript sees this:

```
"ls \"/System/Library/Image Capture\""
```

AppleScript's parser converts `\` to `"` so Unix sees this:

```
ls "/System/Library/Image Capture"
```

ActiveX Automation

ActiveX Automation, often called just Automation, is Microsoft's technology for allowing one program to control another. The program that does the controlling is called the Automation client. The program that is controlled is called the Automation Server. The client initiates things by making calls to the server which carries out the requested actions and returns results.

Automation client programs are most often written in Visual Basic or C++. They can also be written in other programming languages and in various scripting languages such as VBScript, JavaScript, Perl, Python and so on.

As of Igor Pro 5, Igor can play the role of Automation Server. If you want to write a client program to drive Igor, see "Automation Server Overview" in the "Automation Server" help file in "\Igor Pro Folder\Miscellaneous\Windows Automation".

Igor Pro does not directly support playing the role of Automation client. However, it is possible to write an Igor program which generates a script file which can act like an Automation client. See the CallMicrosoftWord experiment in the Igor Pro Folder:Examples:Programming folder.

An intermediate-level C++ programmer can also write an Igor XOP which plays the role of Automation client.

Igor Command Line

This information is for Windows programmers only. You can call Igor Pro from a Windows batch file or even from Igor itself using ExecuteScriptText using this operation-like syntax:

Igor.exe

```
Igor.exe [/I /N /Automation][pathToFileOrCommands][pathToFile]...
```

```
Igor.exe [/I /Q /X /Automation] "commands"
```

```
Igor.exe /SN=num /KEY="key" /NAME="name" [/ORG="org" /QUIT]
```

Parameters

The usual parameter to Igor.exe is a file which Igor opens. It is recommended that both the path to Igor.exe and the path to the file parameter be enclosed in quotes:

```
"C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe" "C:\My Documents\exp.pxp"
```

Multiple files can be opened by appending the path to the file(s) with an intervening space:

```
"C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe" "C:\Dir\exp.pxp" "C:\Dir\exp.dat"
```

With the /X flag, only one parameter is allowed and is interpreted as Igor commands:

```
"C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe" /X "Make/O data=x;Display data"
```

The /SN, /KEY, and /NAME flags must all be used to successfully register Igor Pro. The optional /ORG parameter defaults to "".

Flags

Note: The / symbol can be replaced with a - symbol (ActiveX Automation uses a -Automation parameter when calling Igor Pro).

/Automation Used automatically (along with /I) by the operating system when launching Igor Pro as an Automation Server. The command parameter that the OS sends is defined in the Registry, put there by the Igor installer or by the user, by merging an IgorProCOM.reg file. This flag isn't intended for use in batch files or ExecuteScriptText. For more details on ActiveX Automation Server, see "Automation Server Overview" in the "Automation Server" help file.

It can, however be used from the command line or a batch file to communicate with other programs in combination with /X. The /Automation flag keeps Igor windows hidden, which may be useful when calling Igor Pro from a web server CGI program.

/I Launches a new "instance" of Igor that will open the file or execute the commands. Pressing Ctrl while launching Igor is the same as using the /I flag.

Without /I, files are opened and commands are executed by any Igor.exe that is currently running. If a parameter is an experiment file, the currently open experiment is closed before opening the new one (see the /Y and /N flags).

/KEY="key" Specifies the license activation key. Use a value of the form:

```
/KEY="ABCD-EFGH-IJKL-MNOP-QR"
```

Do not omit the quotes, or it will fail.

/N Forces the current experiment to be closed without saving if any of the file parameters are an experiment file.

To save a currently open experiment, use:

```
Igor.exe /X "SaveExperiment"
```

/NAME="name" Defines the name of the licensed user(s). Cannot be "".

/ORG="org" Specifies the optional name of the licensed organization. Default is "". Because Windows interprets the & symbol to mean "underline the next character when displayed in a dialog window," use && to display one & character in the About Igor dialog.

/Q	Doesn't show Command line: /X "Make/O data=s;Display data" in Igor's history window when using /X or /SN, etc.
/QUIT	Quits Igor Pro after entering license information when used with /SN, /KEY, and /NAME. Otherwise /QUIT is ignored. To quit Igor Pro, use: Igor.exe /X "Quit/N"
/SN=num	Specifies the license serial number.
/X	Executes the commands in the first (and only allowed) parameter. Use semicolons to separate commands.

Example

These Igor commands launch another instance of Igor to open an experiment file:

```
PathInfo Igor // S_path is path to Igor folder in Macintosh file format.
String igorPath= ParseFilePath(5, S_path, "\\ ", 0, 0)+"Igor.exe" // in PC format
ExecuteScriptText "\" + igorPath + "\" /I \"C:\\My Documents\\Experiment.pxp\""
```

These batch file commands register Igor Pro with the given (fictional) serial number and license activation key:

```
Igor.exe /SN=1234567/KEY="ABCD-EFGH-IJKL-MNOP-QR"/NAME="Me" /ORG="You && Me, Inc." /QUIT
```

Igor as a WWW CGI-Bin Server

You can use Igor Pro as part of a Web server on both Macintosh and Windows. For example, you might create a form that allows users to enter parameters and then see an Igor created graph based on the user's inputs.

On the Macintosh your Web server executes a compiled AppleScript (that you write based on our example) that communicates with Igor using the DoScript Apple event.

On Windows, we supply an IgorCGI.exe executable program than communicates with Igor using DDE.

On Windows, we supply an IgorCGI.exe executable program that communicates with Igor Pro using DDE. Another option is to communicate directly using ActiveX Automation Server (see "Automation Server Overview" in the "Automation Server" help file) or on the Igor command line.

On both platforms, we provide example procedures that you keep in the Igor Procedures folder to help you decode the values users enter in the form with their Web browser.

For more information and sample code, see Technical Note PTN004 — "Igor CGI on Macintosh" and Technical Note PTN005 — "Igor CGI on Windows".

File Transfer Protocol (FTP)

The **FTPDownload** (page V-168) and **FTPUpload** (page V-170) operations support simple transfers of files and directories over the Internet. FTPDownload makes it possible to write an Igor procedure that automatically retrieves data from a remote FTP server. FTPUpload makes it possible to transfer results to a remote FTP server.

Since Igor's SaveNotebook operation can generate HTML files from notebooks, it is possible to write an Igor procedure that downloads data, analyzes it, graphs it, and uploads an HTML file to a directory used by a Web server. You can then use the BrowseURL operation to verify that everything worked as expected. For a demo of some of these features, see "Igor Pro Folder:Examples:Feature Demos:Web Page Demo.pxp".

The operating systems don't provide identical support for FTP. Consequently, some features are supported on one OS but not on the other, as noted below.

FTP Limitations

FTPDDownload and FTPUpload run “synchronously”. This means that while the download or upload is being carried out, Igor can not do anything else. Consequently, these operations are not ideal for transferring very large files, which are better handled by a dedicated FTP program.

Igor does not currently provide any way for the user to browse the remote server from within Igor itself.

Igor does not provide any secure way to store passwords. Consequently, you should not use Igor for FTP in situations where tight security is required.

Igor does not provide any support for using proxy servers. Proxy servers are security devices that stand between the user and the Internet and permit some traffic while prohibiting other traffic. If your site uses a proxy server, FTPDownload and FTPUpload may fail. Your network administrator may be able to provide a solution.

Igor does not include operations for listing a server directory, changing a server’s current directory, for creating and deleting directories and for other FTP operations.

See also **FTP Problems** on page IV-195 for a discussion of other problems that you might encounter.

Downloading a File

The following commands transfer a file from an FTP server to a local hard disk:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test:TestFile1.txt" // Macintosh
FTPDDownload/U="ftpTestAccount"/W="dropbox" url, localPath
```

These commands transfer the file TestFile1.txt from the WaveMetrics FTP server into the Test directory on the local hard disk “hd”. The Test directory must already exist on the local hard disk. The TestFile1.txt file may or may not exist on the local hard disk. If it does not exist, the FTPDownload command will create it. If it does exist, FTPDownload will ask if you want to overwrite it. To overwrite it without being asked, use the /O flag.

Warning: If you elect to overwrite it, all previous contents of the local TestFile1.txt file will be obliterated.

As of this writing, “ftpTestAccount” is the user name and “dropbox” is the password for the “test” directory on the WaveMetrics FTP server.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test:FileA.txt"
FTPDDownload/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting file on the local hard disk will be named FileA.txt instead of TestFile1.txt.

FTPDDownload presents a dialog asking you to specify the local file name and location in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist. In the examples above, the parent directory is Test.
3. The specified local file exists and you have not used the /O (overwrite) flag.

Downloading a Directory

The following commands transfer a directory from an FTP server to a local hard disk:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test:TestDir1"
FTPDDownload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

Note the use of the /D flag to specify that you are transferring a directory.

This command transfers the TestDir1 directory from the WaveMetrics FTP server into the Test directory on the local hard disk “hd”. The Test directory must already exist on the local hard disk. The TestDir1 directory

may or may not exist. If it does not exist, the FTPDownload command will create it. If it does exist, FTPDownload will ask if you want to overwrite it. To overwrite it without being asked, use the /O flag.

Warning: If you elect to overwrite it, all previous contents of the local TestDir1 will be obliterated.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test:TestDir2"
FTPDownload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting directory on the local hard disk will be named TestDir2 instead of TestDir1.

Warning: If you elect to overwrite it, all previous contents of the local TestDir2 will be obliterated.

The local path that you specify must not end with a colon or backslash. For example, if you execute:

```
FTPDownload/D "ftp://ftp.wavemetrics.com/pub/test/TestDir1", "hd:Test:TestDir1:"
```

FTPDownload will present a dialog asking you to specify the local directory because the local path ends with a colon and FTPDownload is looking for the name of the directory to be created on the local hard disk.

FTPDownload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The parent directory specified by the local path does not exist. In the examples above, the parent directory is Test.
3. The specified directory (TestDir1 in the example above) exists and you have not used the /O (overwrite) flag.
4. FTPDownload gets an error when it tries to create the specified directory. This could happen, for example, if the directory name that you specify is not a legal directory name. For example, the name might be too long or use characters that are forbidden in the local file system.

Uploading a File

The following commands upload a file to an FTP server:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test:TestFile1.txt"
FTPUpload/U="ftpTestAccount"/W="dropbox" url, localPath
```

These commands transfer the file TestFile1.txt from the local hard disk into the test directory on the WaveMetrics FTP server. The test directory must already exist on the WaveMetrics FTP server. The TestFile1.txt file may or may not exist. If it does not exist, the FTPUpload command will create it. If it does exist, FTPUpload will overwrite it.

Note: The /O flag has no effect on the FTPUpload operation. FTPUpload *always* overwrites an existing server directory, whether /O is used or not.

Warning: If you overwrite a server file, all previous contents of the file will be obliterated.

To overwrite an existing file on the server, you must have permission to delete files on that server. The server administrator determines what permission a particular user has.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile2.txt"
String localPath = "hd:Test:TestFile1.txt"
FTPUpload/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting file on the FTP server will be named TestFile2.txt instead of TestFile1.txt.

FTPUpload presents a dialog asking you to specify the local file in the following cases:

1. You use the /I (interactive) flag.

2. The local parent directory (e.g., Test) or the local file (e.g., TestFile1.txt) does not exist.

Uploading a Directory

The following commands upload a directory to an FTP server:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test:TestDir1"
FTPUpload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

These commands transfer the TestDir1 directory from the local hard disk into the test directory on the WaveMetrics FTP server. The test directory must already exist on the WaveMetrics FTP server. The TestDir1 directory may or may not exist. If it does not exist, the FTPUpload command will create it. If it does exist, FTPUpload will overwrite it.

Note: The /O flag has no effect on the FTPUpload operation. FTPUpload *always* overwrites an existing server directory, whether /O is used or not.

Warning: If you overwrite a server directory, all previous contents of the directory will be obliterated.

To overwrite an existing directory on the server, you must have permission to delete directories on that server. The server administrator determines what permission a particular user has.

Now consider these commands:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir2"
String localPath = "hd:Test:TestDir1"
FTPUpload/D/U="ftpTestAccount"/W="dropbox" url, localPath
```

This does the same thing as the previous example except that the resulting directory on the FTP server will be named TestDir2 instead of TestDir1.

The local path that you specify must not end with a colon or backslash. For example, if you execute:

```
FTPUpload/D "ftp://ftp.wavemetrics.com/pub/test/TestDir1", "hd:Test:TestDir1:"
```

FTPUpload will present a dialog asking you to specify the local directory because the local path ends with a colon and FTPUpload is looking for the name of the directory to be uploaded.

FTPUpload presents a dialog asking you to specify the local directory in the following cases:

1. You use the /I (interactive) flag.
2. The specified directory (TestDir1 in the example above) or any of its parents do not exist.

If you don't have permission to remove and to create directories on the server, FTPUpload will fail and return an error.

FTP Transfer Types

The FTP protocol supports two types of transfers: image and ASCII. Image transfer is appropriate for binary files. ASCII transfer is appropriate for text files.

In an image transfer, also called a binary transfer, the data on the receiving end will be a replica of the data on the sending end. In an ASCII transfer, the receiving FTP agent changes line terminators to match the local convention. On Macintosh, the conventional line terminator is carriage-return (CR, ASCII code 0x0D). On Unix, it is linefeed (LF, ASCII code 0x0A). On Windows, it is carriage-return plus linefeed (CRLF).

If you transfer a text file using an image transfer, the file may not use the local conventional line terminator, but the data remains intact. Igor Pro can display text files that use any of the three conventional line terminators, but some other programs, especially older programs, may display the text incorrectly.

On the other hand, if you transfer a binary file, such as an Igor experiment file, using an ASCII transfer, the file will almost certainly be corrupted. The receiving FTP agent will convert any byte that happens to have the value 0x0D to 0x0A or vice versa. If the local convention calls for CRLF, then a single byte 0x0D will be changed to two bytes, 0x0D0A. In either case, the file will become unusable.

The Windows WinInet library allows Igor to explicitly specify whether an image transfer or an ASCII transfer should be done. The /T flag in the FTPDownload and FTPUpload commands specifies the type of transfer. In the absence of /T, these operations default to an image transfer.

The Macintosh URL Access Manager does not provide a way to explicitly control whether an image or ASCII transfer is done. Consequently, the /T flag is accepted but has no effect. Furthermore, the URL Access Manager documentation is vague on this issue.

FTP Problems

On Mac OS, the behavior of URL Access Manager calls has been buggy and erratic since its inception and remains so now. On Mac OS 10.3 it is nearly useless.

Doing an upload of a directory that contains subdirectories results in an error. This is caused by the Mac OS URL Access Manager sending an incorrect command to the FTP server.

Status messages that Igor receives from the Mac OS during a download may be misleading. For example, you may see “Aborting...” when in fact the transfer has finished successfully. Igor displays these status messages in the history area if you use the /V=*diagnosticMode* flag with bit 2 of *diagnosticMode* set.

The Mac OS URL Access Manager returns error codes that are not valid Mac OS error codes and are not defined in the URL Access Manager documentation. Igor reports these error codes in the history area. If a report says an error is a Mac OS error and the code is positive, this is one of the undefined error codes. On Mac OS X, URL Access sometimes returns other error codes that have no bearing on the actual error.

On Windows, we experienced just one minor problem. If you attempt to connect to an FTP host that does not respond, for example, if you provide an incorrect URL or the computer is turned off, Igor may hang up for as long as several minutes. During this time, the Windows operating system is in control and there is no way for Igor to shorten this wait.

FTP Troubleshooting

FTP involves a lot of hardware and software on both ends and a network in between. This provides ample opportunity for errors.

Here are some tips if you experience errors using the FTPDownload and FTPUpload operations.

1. Use an FTP browser (e.g., Fetch or Interarchy on Macintosh and Internet Explorer on Macintosh or Windows) to connect to the FTP site. This confirms that your network is operating, the FTP server is operating, and that you are using the correct URL.
2. Use an FTP browser to verify that the user name and password that you are using is correct or that the server allows anonymous FTP access.
3. Use an FTP browser to verify that the directory structure of the FTP server is what you think it is.
4. Using an FTP browser, do the download or upload that you are attempting to do with FTPDownload or FTPUpload. This will verify that you have sufficient permissions on the server.
5. Use /V=7 to display FTPDownload or FTPUpload status information in the history area. The status information on Macintosh is useless. On Windows, however, it shows the FTP server responses which may provide clues.
6. Try the simplest transfer you can. For example, try to download a single file that you know exists on the server.
7. If you have access to the FTP server, examine the FTP server log for clues.

Operation Queue

Igor supports an operation queue that allows for the execution of what were previously illegal operations. Items in the operation queue execute only when nothing else is happening. Macros and functions must not be running and the command line must be empty.

You may append to the operation queue using

```
Execute/P <command string>
```

Chapter IV-10 — Advanced Programming

The /P posts the command to operation queue. You can also specify the /Q (quiet) or /Z (ignore error) flags. See **Execute/P** operation (page V-130) for details about /Q and /Z.

The command string may be either special commands that are unique to the operation queue or may be ordinary Igor commands. The special commands are:

INSERTINCLUDE *procedureSpec*

DELETEINCLUDE *procedureSpec*

COMPILEPROCEDURES

NEWEXPERIMENT

LOADFILE *filePath*

MERGEEXPERIMENT *filePath*

INSERTINCLUDE and DELETEINCLUDE insert or delete #include lines in the main procedure window. *procedureSpec* is whatever you would use in a #include statement except for “#include” itself.

COMPILEPROCEDURES does just what it says, compiles procedures. You must call it after operations such as INSERTINCLUDE that modify, add, or remove procedure files.

NEWEXPERIMENT closes the current experiment without saving.

LOADFILE opens the file specified by *filePath*. *filePath* is either a full path or a path relative to the Igor Folder. The file may be any of a number of file types Igor can open. If the file is an experiment, be sure to execute NEWEXPERIMENT first to avoid putting up a dialog. If you want to save the changes in an experiment before loading another, you can use the standard SaveExperiment operation.

MERGEEXPERIMENT merges the experiment file specified by *filePath* into the current experiment. Before using this, make sure you understand the caveats regarding merging experiments. See **Merging Experiments** on page II-27 for details.

Note: The special operation queue keywords must be all caps and must have one space after the keyword.

Here is an example:

```
Function DemoQueue()  
    Execute/P "INSERTINCLUDE <Multi-peak fitting 1.3>"  
    Execute/P "INSERTINCLUDE <Peak Functions>"  
    Execute/P "COMPILEPROCEDURES "  
    Execute/P "CreateFitSetupPanel() "  
    Execute/P "Sleep 00:00:04"  
    Execute/P "NEWEXPERIMENT "  
    Execute/P "LOADFILE :Examples:Feature Demos:Live mode.pxp"  
    Execute/P "DoWindow/F Graph0"  
    Execute/P "StartButton(\"StartButton\") "  
End
```

In the above example, the example experiment Live mode.pxp was chosen because it happened to have a .pxp extension which allows the example to work on both Macintosh and Windows — the file name and path must be exact.

One important use of the operation queue is providing easy access to useful procedure packages. The Igor Procedures folder contains a procedure file that has Menu definitions similar to the following (**Caution!** The three commands under the example submenu are very long and are wrapped to fit on the page):

```
Menu "Analysis"  
    Submenu "Packages"  
        "Multipeak Fitting",Execute/P "INSERTINCLUDE <Multi-peak fitting 1.3>;Execute/P  
INSERTINCLUDE <Peak Functions>;Execute/P "COMPILEPROCEDURES ";Execute/P "CreateFitSetupPanel() "  
        "Wave Arithmetic",Execute/P "INSERTINCLUDE <Wave Arithmetic Panel>;Execute/P  
COMPILEPROCEDURES ";Execute/P "InitWaveArith() "  
        "Probability Graph",Execute/P "INSERTINCLUDE <Probability Graph>;Execute/P  
COMPILEPROCEDURES ";Execute/P "Probability_Axis() "  
    End  
End
```

To try this out, start Igor and choose one of the items from the Analysis→Packages menu.

User-Defined Hook Functions

Igor Pro will call specific user-defined functions, called “hook” functions, if they exist, when Igor Pro performs certain actions. Hook functions allow savvy programmers to customize Igor’s behavior. In some cases the hook function may inform Igor that the action has been completely handled, and that Igor shouldn’t perform the action. For example, you could write a hook function to load data from a certain kind of text file that Igor can not handle directly.

The names of the predefined hook functions (and when they are called) are shown below.

Note: As of Igor Pro 5, use of these predefined function names is discouraged. The preferred method is to call the **SetIgorHook** operation (see page V-496) to associate (at runtime) one or more arbitrarily-named user-defined function(s) with an action. SetIgorHook allows combining procedure files that each want to be notified when Igor performs “hookable” actions. Using the specific function names shown below does not allow that.

Alternatively, the use of predefined **Static Hook Functions** (see page IV-207) (Igor Pro 5.02 or later) may well solve problems that SetIgorHook can not: namely initialization of a “package” of procedures when Igor starts up.

Action	Hook Function Called
A file or experiment has just been opened	AfterFileOpenHook
A target window has been created	AfterWindowCreatedHook
An experiment is about to be saved	BeforeExperimentSaveHook
A file or XOP is about to be opened	BeforeFileOpenHook
Igor about to open a new experiment	IgorBeforeNewHook
Igor about to quit	IgorBeforeQuitHook
Igor building and enabling menus or about to handle a menu selection	IgorMenuHook
Igor quitting	IgorQuitHook
Igor starting or new experiment	IgorStartOrNewHook

In addition, you can attach a hook function to a particular window, using the SetWindow operation. See the **SetWindow** operation on page V-504 for information on window hook functions. This section deals only with the general hook functions that are associated with events and not with a particular window.

To create hook functions, you must write functions with the specified names and store them in any procedure file. (If you store the procedure file in the Igor Procedures folder, Igor will automatically open the file and compile the functions when it starts up and will execute the IgorStartOrNewHook function if it exists.)

You can use BeforeFileOpenHook to load your own custom data files via drag-and-drop. Your BeforeFileOpenHook function must detect your type of file by examining the file’s type and creator codes or by examining its contents. If the file is of the right type, you then call your XOP or use the FBinRead or FReadLine operation to load data from the file. You then avoid opening the file by returning a value of 1. If the file is not your file, you return 0, which loads the file. See the examples in the **BeforeFileOpenHook** operation (page IV-202) description.

Windows system files with .bin, .com, .dll, .exe, and .sys extensions aren’t passed to the hook functions.

This example checks the type of file being opened. If it is an Excel file, it loads the file using the XLLoadWave XOP. It is intended to allow you to load an Excel file by dragging its icon onto the Igor Pro application icon.

```
Function BeforeFileOpenHook(refNum, fileName, path, type, creator, kind)
    Variable refNum, kind
    String fileName, path, type, creator
```

```
String xop="XLLoadWave"      // name of XOP command to load data
Variable isExcel,handedOpen=0

// This tests the file name extension.
String extension = ParseFilePath(4, fileName, ":", 0, 0)
isExcel = CmpStr(extension, "xls")==0

// This tests the Macintosh file type.
// "XLS ", XLS3, XLS4, XLS5, XLW4, XLW5 are Excel file types
isExcel += CmpStr(type[0,2],"XLS")==0
isExcel += CmpStr(type[0,2],"XLW")==0

if (isExcel)
    if (exists(xop)==4) // Load only if XOP installed
        Close refNum
        String cmd
        cmd = xop + "/A/T/P="+path+" \" "+fileName+"\" "
        Execute cmd
        handedOpen=1      // we handled the open event
    endif
endif

return handedOpen // 1 tells Igor not to open the file itself
End
```

A return value of 1 indicates that you handled the open file event and that Igor should not open it. A return value of 0 specifies that you did not handle the event and that Igor should deal with it.

For more examples, see **BeforeFileOpenHook** on page IV-202.

Another possible use of a hook function is to predefine global variables, strings, waves, symbolic paths, or data folders when a new experiment is started up:

```
Function IgorStartOrNewHook(igorApplicationNameStr)
    String igorApplicationNameStr

    NewPath/O pathToMyData "HD:My Data:"
    Variable/G root:V_no_MIME_TSV_Load = 1 // See AfterFileOpenHook
    Make/O/T root:TestNames={"RDC #1","KLZ #2","ARB #3","MOR #4"}
End
```

The following sections describe the individual hook functions in detail.

AfterFileOpenHook

AfterFileOpenHook(refNum, fileNameStr, pathNameStr, fileTypeStr, fileCreatorStr, fileKind)

AfterFileOpenHook is a user-defined function that Igor calls *after* it has opened a file or experiment that the user has double-clicked or dragged onto the Igor icon, or a file opened as a result of an “open” Apple event from another program (such as a Web browser).

Note: AfterFileOpenHook is not called when the Open File or Load Waves menus are selected.

The parameters contain information about the file, which has already been opened for read-only access.

AfterFileOpenHook’s return value is ignored unless *fileKind* is 9. If the returned value is zero, the default action is performed.

Parameters

Variable *refNum* is the file reference number. You use this number with the **FReadLine**, **FStatus**, **FSetPos**, **FBinWrite**, **FBinRead**, **fprintf**, and **wfprintf** operations to read from or write to the file. Normally, the file is opened for read-only operations, but for experiment files and XOP files, *refNum* will be -1, meaning the file has not been opened for you. You can close the file and reopen it for write access, if you wish.

Igor always closes the file when the user-defined function returns, and *refNum* becomes invalid (don't store the value of *refNum* in a global for use by other routines, since the file it refers to has been closed).

String *fileNameStr* contains the name of the file (including any extension).

String *pathNameStr* contains the name of the symbolic path. *pathNameStr* is not the value of the path. Use the PathInfo operation to determine the path's value.

String *fileTypeStr* contains the file type. This was conceived with the Macintosh in mind. Under Windows, this is usually the file extension, such as ".txt". However, if the file is an Igor-registered file, then *fileTypeStr* is set to one of the Macintosh file type codes (for cross-platform compatibility). Some Igor-registered files types are listed in the following table:

Type of File	<i>fileTypeStr</i> Contents	Extension
Igor Experiment, packed	IGsU	.pxp
Igor Experiment, packed, stationery / template	IGsS	.pxt
Igor Experiment, unpacked	IGSU	.uxp
Igor Experiment, unpacked, stationery / template	IGSS	.uxt
Igor XOP	IXOP	.xop
Igor Procedure	TEXT	.ipf
Igor Notebook (formatted)	WMT0 (zero, not oh)	.ifn
Igor Notebook (unformatted)	TEXT	.txt
Igor Notebook stationery / template (formatted)	WMTS	.ift
Igor Text (data and commands)	TEXT	.itx or .awav
Igor Binary	IGBW	.ibw or .bwav
Igor Published Edition	edtp	
Igor Help	WMT0 (zero, not oh)	.ihf

In addition, some other nonregistered extensions are converted to Mac-like file types:

Type of File	<i>fileTypeStr</i>	Extension
Encapsulated PostScript	EPS (trailing space)	.eps or .epsf
Rich Text	RTF (trailing space)	.rtf
Internet Shortcut	LINK	.url*
Text (also unformatted Igor Notebook)	TEXT	.txt
Batch file	TEXT	.bat
ASCII or data	TEXT	.csv, .dat, or .tsv

* The .url extension isn't shown in Windows Explorer windows.

Regardless of the value of *fileTypeStr*, the *fileNameStr* parameter has the file name and the extension.

String *fileCreatorStr* contains the creator code. Also conceived with the Macintosh in mind, this is usually "IGR0" for Igor-registered files, the full file path to the application registered to open the file, or the full file path to the file itself if unregistered by any application.

Chapter IV-10 — Advanced Programming

Some Windows examples are:

File	<i>fileCreatorStr</i>
My Experiment.pxp	IGR0 (zero, not oh)
My Igor Data.ibw	IGR0 (zero, not oh)
Better.bmp	C:\Program Files\MS\MSPAIN.T.EXE
AFile.bat	C:\Mine\AFile.bat

String *fileCreatorStr* contains the creator code. Some Macintosh examples are:

Application	<i>fileCreatorStr</i> Contents
Igor or Igor Pro	IGR0 (zero, not oh)
TeachText or SimpleText	ttxt

Variable *fileKind* is a number that identifies what kind of file Igor thinks it is. If the user's AfterFileOpenHook routine returns 0, Igor performs the Default Action listed in the table:

Kind of File	<i>fileKind</i>	Default Action, if Any
Unknown	0	
Igor Experiment, packed (stationery, too)	1	
Igor Experiment, unpacked (stationery, too)	2	
Igor XOP	3	
Igor Binary File	4	
Igor Text (data and commands)	5	
Text, no numbers detected in first two lines	6	
General Numeric text (no tabs)	7†	
Numeric text	8	
Tab-Separated-Values		
Numeric text	9	Display loaded data in a new table and a new graph.
Tab-Separated-Values, MIME		
Text, with tabs	10	
Igor Notebook (unformatted or formatted)	11	
Igor Procedure	12	
Igor Help	13	

Details

AfterFileOpenHook's return value is ignored, except when *fileKind* is 9 (Numeric text, Tab-Separated-Values, MIME). If you return a value of 0, Igor executes the default action, which displays the loaded data in a table and a graph. If you return a value of 1, Igor does nothing.

Note: Another way to disable the MIME-TSV default action is define a global variable named V_no_MIME_TSV_Load (in the root data folder) and set its value to 1. In this case any file of *fileKind* = 9 is reassigned a *fileKind* of 8.

The default action for *fileKind* = 9 makes Igor a MIME-TSV document Helper Application for Web browsers such as Netscape or Internet Explorer.

The exact criteria for Igor to consider a file to be of kind 9 are:

- *fileTypeStr* must be "TEXT" or "WMT0" (that's a zero, not an oh).
- Either the first line of the file must begin with a # character, or the name of the file must end with ".tsv" in either lower or upper case.
- The first line must contain one or more column titles. If the line starts with a # character, the first column title must not start with "include", "pragma" or the ! character. Spaces are allowed in the titles, but if two or more title columns are present, they must be separated by one tab character.
- The second line must contain one or more numbers. If two or more numbers, they must be separated by one tab character, and the first line's words must also be separated by tabs.

When the MIME-TSV file contains one column of data, it is graphed as a series of Y values.

Short columns (less than 50 values) are graphed with lines and markers, longer columns with lines only. Preferences are turned on when the graph is made.

Two columns are assumed to be X followed by Y, and are graphed as Y versus X. More columns do not affect the graph, though they are shown in the table.

Example

```
// This hook function prints the first line of opened TEXT files
// into the history area
Function AfterFileOpenHook(refNum,file,pathName,type,creator,kind)
    Variable refNum,kind
    String file,pathName,type,creator
    // Check that the file is open (read only), and of correct type
    if( (refNum >= 0) && (CmpStr(type,"TEXT")==0) ) // also "text", etc.
        String line1
        FReadLine refNum, line1 // Read the line (and carriage return)
        Print line1 // Print line in the history window.
    endif
    return 0 // don't prevent MIME-TSV from displaying
End
```

See Also

BeforeFileOpenHook and **SetIgorHook**.

AfterWindowCreatedHook

AfterWindowCreatedHook(windowNameStr, winType)

AfterWindowCreatedHook is a user-defined function that Igor calls when a target window is first created.

AfterWindowCreatedHook can be used to set a window hook on target windows created by the user or by other procedures.

Parameters

String *windowNameStr* contains the name of the created window.

Variable *winType* is the type of the window, the same value as returned by **WinType**.

Details

"Target windows" are graphs, tables, layout, panels, and notebook windows.

AfterWindowCreatedHook is not called when an Igor experiment is being opened.

Igor ignores the value returned by AfterWindowCreatedHook.

See Also

SetWindow, **SetIgorHook**, and **User-Defined Hook Functions** on page IV-197.

BeforeExperimentSaveHook

BeforeExperimentSaveHook(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

BeforeExperimentSaveHook is a user-defined function that Igor calls when an experiment is about to be saved by Igor.

Igor ignores the value returned by BeforeExperimentSaveHook.

Parameters

For a full explanation of the parameters, see **AfterFileOpenHook** on page IV-198.

Variable *refNum* is -1. The experiment file is not open.

String *fileNameStr* contains the name of the experiment file (including any extension).

String *pathNameStr* contains the name of the symbolic path.

String *fileTypeStr* contains the file type code.

String *fileCreatorStr* contains the file creator code.

Variable *fileKind* is a number that identifies what kind of file Igor will be saving:

Kind of File	<i>fileKind</i>
Igor Experiment, packed*	1
Igor Experiment, unpacked*	2

* Including stationery experiment files.

Details

You can determine the full directory and file path of the experiment by calling the **PathInfo** operation with *\$pathNameStr*.

Example

This (somewhat frivolous) example prints the full file path of the about-to-be-saved experiment to the history area, and deletes all unused symbolic paths.

```
#pragma rtGlobals=1          // treat S_path as local string variable
Function BeforeExperimentSaveHook(rN,fileName,path,type,creator,kind)
    Variable rN,kind
    String fileName,path,type,creator
    PathInfo $path           // puts path value into (local) S_path
    Printf "Saved \"%s\" experiment\r",S_path+fileName
    KillPath/A/Z             // Delete all unneeded symbolic paths
End
```

See Also

The **SetIgorHook** operation.

BeforeFileOpenHook

BeforeFileOpenHook(*refNum*, *fileNameStr*, *pathNameStr*, *fileTypeStr*, *fileCreatorStr*, *fileKind*)

BeforeFileOpenHook is a user-defined function that Igor calls when a file *is about to be opened* by Igor because the user dragged it onto the Igor icon, double-clicked it, or because Igor received an “open” Apple event from another program (such as a Web browser).

Note: BeforeFileOpenHook is not called when the Open File or Load Waves menu is selected.

The parameters contain information about the file, which has already been opened for read-only access.

The value returned by BeforeFileOpenHook informs Igor whether the user-defined function handled the open and therefore Igor should not perform its default action. In some cases, this return value is ignored, and Igor performs the default action anyway.

Parameters

(For a full explanation of the parameters, see **AfterFileOpenHook** on page IV-198.)

Variable *refNum* is the file reference number.

String *fileNameStr* contains the name of the file (including any extension).

String *pathNameStr* contains the name of the symbolic path.

String *fileTypeStr* contains the file type code.

String *fileCreatorStr* contains the file creator code.

Variable *fileKind* is a number that identifies what kind of file Igor thinks it is:

Kind of File	<i>fileKind</i>	Default Action, if Any
Unknown	0	
Igor Experiment, packed *	1	(Hook not called)
Igor Experiment, unpacked *	2	(Hook not called)
Igor XOP	3	
Igor Binary file	4	Data loaded
Igor Text (data and commands)	5	Data loaded, commands executed
Text, no numbers detected in first two lines	6	Opened as unformatted notebook
General Numeric text (no tabs)	7	Data loaded as general text
Numeric text Tab-Separated-Values	8	Data loaded as delimited text
Numeric text Tab-Separated-Values, MIME	9	Display loaded data in a new table and a new graph.
Text, with tabs	10	Opened as unformatted notebook
Igor Notebook (unformatted or formatted)	11	Opened as notebook
Igor Procedure	12	<i>Always</i> opened as procedure file
Igor Help	13	<i>Always</i> opened as help file

* Including stationery experiment files.

Details

BeforeFileOpenHook must return 1 if Igor is not to take action on the file (it won't be opened), or 0 if Igor is permitted to take action on the file. Igor ignores the return value for *fileKind* values of 3, 12, and 13. The hook function is not called for Igor experiments (*fileKind* values of 1 and 2).

Igor always closes the file when the user-defined function returns, and *refNum* becomes invalid (don't store the value of *refNum* in a global for use by other routines, since the file it refers to has been closed).

Example

This example checks the first line of the file about to be opened to determine whether it has a special, presumably user-specific, format. If it does, then LoadMyFile (another user-defined function) is called to load it. LoadMyFile presumably loads this custom data file, and returns 1 if it succeeded. If it returns 0 then Igor will open it using the Default Action from the above table.

Another example can be found in the discussion in **User-Defined Hook Functions** on page IV-197.

```
Function BeforeFileOpenHook(refNum, fileName, path, type, creator, kind)
    Variable refNum, kind
    String fileName, path, type, creator

    Variable handledOpen=0
    if( CmpStr(type, "TEXT")==0 )           // text files only
        String line1
```

```
FReadLine refNum, line1 // First line (and carriage return)
if( CmpStr(line1[0,4],"XYZZY") == 0 ) // My special file
    FSetPos refNum, 0 // rewind to start of file
    handledOpen= LoadMyFile(refNum) // returns 1 if loaded OK
endif
endif
return handledOpen // 1 tells Igor not to open the file
End
```

See Also

AfterFileOpenHook and **SetIgorHook**.

IgorBeforeNewHook

IgorBeforeNewHook(*igorApplicationNameStr*)

IgorBeforeNewHook is a user-defined function that Igor calls before a new experiment is opened in response to the New Experiment, Revert Experiment, or Open Experiment menu items in the File menu.

You can use IgorBeforeNewHook to clean up the current experiment, or to avoid losing unsaved data even if the user chooses to not save the current experiment.

Igor ignores the value returned by IgorBeforeNewHook.

Parameters

igorApplicationNameStr contains the name of the currently running Igor Pro application.

See Also

IgorStartOrNewHook and **SetIgorHook**.

IgorBeforeQuitHook

IgorBeforeQuitHook(*unsavedExp*, *unsavedNotebooks*, *unsavedProcedures*)

IgorBeforeQuitHook is a user-defined function that Igor calls just before Igor is about to quit (before any save-related dialogs have been presented).

Parameters

Variable *unsavedExp* is 0 if the experiment is saved, 1 if unsaved.

Variable *unsavedNotebooks* is the count of unsaved notebooks.

Variable *unsavedProcedures* is the count of unsaved procedures.

Note: The save state of “adopted” procedures or notebooks is part of *unsavedExp*, not *unsavedNotebooks* or *unsavedProcedures*. See **Creating a New Notebook File** on page III-4 and **Adopting a Procedure File** on page III-336.

Details

IgorBeforeQuitHook will normally return 0. In these cases it will present the “Do you want to save” dialogs, and if the user approves, it will call IgorQuitHook.

If IgorBeforeQuitHook returns 1, then the current experiment, notebooks, or procedures will not be saved; no dialogs will be presented to the user, and it will not call IgorQuitHook.

See Also

IgorQuitHook and **SetIgorHook**.

IgorMenuHook

IgorMenuHook(*isSelection*, *menuStr*, *itemStr*, *itemNo*, *topWindowNameStr*, *wType*)

IgorMenuHook is a user-defined function that Igor calls just before and just after menu selection (whether by mouse or keyboard).

Parameters

Variable *isSelection* is 0 before a menu item has been selected, 1 when a menu item has been selected.

String *menuStr* is the name of the selected menu (in English and as used by `SetIgorMenuMode`). *menuStr* is "" when *isSelection* is 0.

String *itemStr* is the name of the selected menu item or "" when *isSelection* is 0.

Variable *itemNo* is the item number of the selected menu item; 1 is the first item in the selected menu. *itemNo* is 0 when *isSelection* is 0.

String *topWindowNameStr* is the name of the top window (the window to which window-specific menu commands like Copy and Paste apply).

Not all windows have names, so *topWindowNameStr* is set specially in those cases:

Window	<i>topWindowNameStr</i>
graph, panel, notebook, layout, table	Window name. See the Window Control Dialog and DoWindow operation (page V-110) about window names.
command/history window	"kwCmdHist" (as used for GetWindow).
procedure window	The window title as shown in the window's title bar. The standard procedure window is "Procedure".
Igor Extensions ("XOP") window	The window title as shown in the window's title bar.

Variable *wType* identifies the kind of window that *topWindowNameStr* names. It returns the same values as the **WinType** function (see page V-665). For procedure windows *wType* is 8, for the command/history window it is -1, and for XOP windows or unknown windows *wType* is 0.

Details

`IgorMenuHook` is called with *isSelection* set to 0 after all the menus have been enabled and before a mouse click or Command-key (Macintosh) or Ctrl+key (Windows) is handled.

The return value should normally be 0. If the return value is nonzero (1 is usual) then the top window's hook function (see **SetWindow** operation on page V-504) is not called for the enablemenu event.

`IgorMenuHook` is called with *isSelection* set to 1 after the menu has been selected and before Igor has acted on the selection.

If the hook function returns 0, Igor proceeds to call the top window's hook function for the menu event. (If the window hook function is present and returns nonzero Igor ignores the menu selection, otherwise Igor handles the menu selection normally.)

If the hook function returns nonzero (1 is again usual), Igor does not call the remaining hook functions and Igor ignores the menu selection.

Menu Event Details

Menu building, enabling, and selection by Igor, user menus, window hooks and `IgorMenuHook` are sequenced this way:

Menu building and enabling are performed in this order:

- 1) Igor updates built-in menus according to the frontmost and the target window.
- 2) Dynamic user-defined menus are updated.
- 3) `IgorMenuHook(0, ...)` is called. If `IgorMenuHook` returns nonzero (which is not recommended), step 4 is skipped.
- 4) The top window's window hook function(s) (see **SetWindow** operation on page V-504) is (are) called with the enablemenu event. The return value is ignored.
- 5) Igor extensions update their menus and their items in built-in menus.

Menu selections are handled in this order:

- 1) Igor extensions may handle the menu selection. If the selection was handled, the following steps are skipped.
- 2) If the selected menu item is not one of Igor's built-in menus, the steps 3 and 4 are skipped.
- 3) The top window's window hook(s) is (are) called with the menu event. If a hook returns nonzero

the remaining window hooks and the following steps are skipped.

- 4) IgorMenuHook(1, ...) is called. If IgorMenuHook returns nonzero, the following steps are skipped.
- 5) If a user-defined menu was chosen, Igor executes the associated command, and the remaining step is skipped.
- 6) Igor handles the selection of a built-in menu item.

Example

This user hook function invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for all graphs, preventing Igor from performing the usual Copy.

```
Function IgorMenuHook(isSel, menuStr, itemStr, itemNo, topWindowName, wt)
    Variable isSel
    String menuStr, itemStr
    Variable itemNo
    String topWindowName
    Variable wt

    Variable handled= 0
    if( CmpStr(menuStr,"Edit") == 0 && CmpStr(itemStr,"Copy") == 0 )
        if( wt == 1 ) // graph
            // DoIgorMenu would cause recursion, so we defer execution
            Execute/P/Q/Z "DoIgorMenu \"Edit\", \"Export Graphics\""
            handled= 1
        endif
    endif

    return handled
End
```

See Also

SetWindow, Execute, and SetIgorHook.

IgorQuitHook

IgorQuitHook(igorApplicationNameStr)

IgorQuitHook is a user-defined function that Igor calls when Igor is about to quit.

The value returned by IgorQuitHook is ignored.

Parameters

String *igorApplicationNameStr* contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

Details

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name. See the example in **IgorStartOrNewHook** on page IV-206.

See Also

IgorBeforeQuitHook and SetIgorHook.

IgorStartOrNewHook

IgorStartOrNewHook(igorApplicationNameStr)

IgorStartOrNewHook is a user-defined function that Igor calls when starting up and when creating a new experiment. It is also called if Igor is launched as a result of double-clicking a saved Igor experiment.

Igor ignores the value returned by IgorStartOrNewHook.

Parameters

String *igorApplicationNameStr* contains the name of the currently running Igor Pro application (including the .exe extension under Windows).

Details

You can determine the full directory and file path of the Igor application by calling the **PathInfo** operation with the Igor path name.

Example

This example prints the full path of Igor application and sets the annotation halo size to zero whenever Igor starts up or creates a new experiment:

```
#pragma rtGlobals=1          // treat S_path as local string variable

Function IgorStartOrNewHook(igorApplicationNameStr)
    String igorApplicationNameStr

    Variable/G root:V_TBBufZone= 0 // See General Annotation Properties
                                   // on page III-46
    PathInfo Igor                // puts path value into (local) S_path
    printf "%s" (re)starting\r", S_path + igorApplicationNameStr
End
```

See Also

IgorBeforeNewHook and **SetIgorHook**.

Static Hook Functions

As of Igor Pro 5.02 or later, you can use multiple fixed-name hook functions by making them “static” (local) to a procedure file. *Each* procedure file can contain one fixed-name static hook function. Igor Pro 5.02 or later searches all procedure files for these static fixed-name hook functions and calls them during the Actions listed in the previous section.

To be clear, the first two lines of nonstatic fixed-name hook functions look like this:

```
Function IgorStartOrNewHook(igorApplicationNameStr)
    String igorApplicationNameStr
```

They will be called for by all versions of Igor Pro 5.0 or later (most will be called in Igor Pro 4 as well).

Static fixed-name hook functions look like this:

```
static Function IgorStartOrNewHook(igorApplicationNameStr)
    String igorApplicationNameStr
```

Igor Pro 5.02 or later calls the (possibly multiple) static hook functions after the **SetIgorHook** (see page V-496) functions are called and before the one nonstatic fixed-name hook function is called. The static hook functions themselves are called in the order in which their procedure file was opened. You should not rely on any execution order among the static hook functions. However, any hook function which returns a nonzero result prevents remaining hook functions from being called and prevents Igor from performing its usual processing of the hook event. In most cases hook functions should exercise caution in returning any value other than 0. For hook functions only, returning a NaN or failing to return a value (which returns a NaN) is considered the same as returning 0.

Note: The **IgorStartOrNewHook** (see page IV-206) hook function is especially useful to initialize a related set of procedures packaged together in an auxiliary procedure file.

Data Acquisition

Igor Pro provides a number of facilities to allow working with live data:

- Live mode traces in graphs
- FIFOs and Charts
- Background task
- External operations and external functions
- Controls and control panels
- User-defined functions

Live mode traces in graphs are useful when you acquiring complete waveforms in a single short operation and you want to update a graph many times per second to create an oscilloscope type display. See **Live Graphs and Oscilloscope Displays** on page II-277 for details.

First-In-First-Out buffers (FIFOs) and Charts are used when you have a continuous stream of data that you want to capture and, perhaps, monitor. See **FIFOs and Charts** on page IV-208 details.

You can set up a background task that will periodically perform data acquisition while allowing you to continue to work with Igor in the foreground. The background operations are *not* done using interrupts and therefore are easily disrupted by foreground operations (that would be you). The backgrounder is only useful for relatively infrequent tasks that can be quickly accomplished and do not cause a cascade of graph updates or other things that take a long time. See **FIFOs and Charts** on page IV-208 for details.

You can create an instrument-like front panel for your data acquisition setup using user-defined controls in a panel window. Refer to Chapter III-14, **Controls and Control Panels**, for details. There are many example experiments that can be found in the Examples folder.

Igor Pro comes with an XOP called VDT2 for communicating with instruments via serial port (RS232) and another XOP called NIGPIB2 for communicating via General Purpose Interface Bus (GPIB). See the Igor Pro Folder:More Extensions:Data Acquisition folder.

Sound I/O can be done using the built-in **SoundInRecord** and **PlaySound** operations.

WaveMetrics produces the NIDAQ Tools software package for doing data acquisition using National Instruments cards. NIDAQ Tools is built on top of Igor using all of the techniques mentioned in this section. Information about NIDAQ Tools is available via the WaveMetrics Web site <<http://www.wavemetrics.com/Products/NIDAQTools/nidaqtools.html>>.

Third parties have created data acquisition packages that use other hardware. Information about these is also available at <<http://www.wavemetrics.com/Products/thirdparty.html>>.

If an XOP package is not available for your hardware you can write your own. For this, you will need to purchase the XOP Toolkit product from WaveMetrics. See **Creating Igor Extensions** on page IV-151 for details.

FIFOs and Charts

The following information will be of interest principally to people engaged in data acquisition activities. It is possible that there are other uses for these capabilities and you may want to read the following summary to see if you can think of any alternate applications. Most people who use FIFOs and Chart controls will do so via canned packages provided by expert Igor programmers (such as yourself) and will not need to know the details that follow.

Summary

FIFOs are invisible data objects that can act as a First-In-First-Out buffer between a data source and a disk file. Data is placed in a FIFO either via the AddFIFOData operation or via an XOP package designed to interface to a particular piece of hardware. Chart controls provide a graphical view of a portion of the data in a FIFO. When data acquisition is complete a FIFO can operate as a bidirectional buffer to a disk file. This allows the user to review the contents of a file by scrolling the chart “paper” back and forth. FIFOs can be used without a chart but charts have no use without a FIFO to monitor.

FIFOs can have an arbitrary number of channels each with its own number type, scaling info and units. All channels of a given FIFO share a common “timebase”. A given chart control can monitor an arbitrary selection of channels from a single FIFO. Each trace can have its own display gain, color and line style and can either have its own area on the “paper” or can share an area with one or more other traces. There can be multiple chart controls active at one time in one or more panel or graph windows.

Here is a typical chart control:

Programming with FIFOs

You can create a FIFO by using the NewFIFO operation. When you are done using a FIFO you use the KillFIFO operation. A freshly created FIFO is not useful until either channels are created with the NewFIFOChan operation or until the FIFO is attached to a disk file for review using a variant of the CtrlFIFO operation. You can obtain information about a FIFO using the FIFOStatus operation and you can extract data from a FIFO using the FIFO2Wave operation. Once a FIFO is set up and ready to accept data, you can insert data using the AddFIFOData operation. Alternately, you can insert data using an XOP package. Once data is stored in a file you can review the data using a FIFO or extract data using user-defined functions. See the example experiment, “FIFO File Parse”, for sample utility routines.

As with background tasks, FIFOs are considered transient objects — they are not saved and restored as part of an experiment.

A FIFO does not need to be attached to a file to be useful. Note, however, that the oldest data will be lost when a FIFO overflows.

A FIFO set up to acquire data does not become valid until the start command is issued. Chart controls will report invalid FIFOs on their status line. FIFO2Wave will give an error if it is invoked on an invalid FIFO. A stopped FIFO remains valid until the first command is issued that could potentially change the FIFO's setup.

Data in a running FIFO is written to disk when Igor notices that the FIFO is half full or when the AddFIFOData command is issued and the FIFO is full. The amount of time it takes to write data to disk can be quite considerable and at the same time unpredictable. If the computer disk cache size is large then writes to disk will be less frequent but when they do occur they will take a long time. This will matter to you most if you are attempting to take data rapidly using software (perhaps using an Igor background task). If you are taking data via interrupt transfer to an intermediate buffer of adequate size or if your hardware has an adequate internal buffer then the disk write latency may not be a concern. If dead time due to disk writes is a concern then you may want to decrease the size of the disk cache and you may want to run with a relatively small FIFO. Note that if you change the size of the disk cache you may have to reboot for the change to take effect.

When the stop command is given to a running FIFO then it goes into review mode and remains valid. If the FIFO is attached to a file then the entire contents of the file can be reviewed or be transferred to a wave using the FIFO2Wave command.

The act of attaching a FIFO to an existing file for review using the rfile keyword of the CtrlFIFO command reads in the file contents and sets itself up for review. You should not use the NewFIFOChan command or any of the other CtrlFIFO keywords except size. Here is all that is required to review a preexisting file:

```
Variable refnum
Open/R/P=mypath refnum as "my file"
NewFIFO dave
CtrlFIFO dave,rfile=refnum
```

If any chart controls have been set up to monitor FIFO dave then they will automatically configure themselves to display all the channels of dave using default parameters.

Chapter IV-10 — Advanced Programming

The connection between FIFOs and chart controls relies on Igor's dependency manager. The dependency manager does not automatically run during function execution — you have to explicitly call it by executing the DoUpdate command.

The dependency manager sends messages to a chart control when:

- a FIFO is created
- a FIFO is killed
- a FIFO becomes valid (start command)
- data is added to a FIFO

In particular, if inside a user function, you kill a FIFO and then create it again you should call DoUpdate after the kill so that the chart control notices the kill and can get ready for the creation.

FIFO File Format

This information is for users who may wish to create FIFO files with their own programs or for those who need to analyze data stored in a FIFO file. You will need to have a reading familiarity with the C programming language to understand the following. Note, the following information may be out of date. For the most up to date information, refer to the most recent version of the auxiliary file named NamedFIFO.h located in the "Miscellaneous:More Documentation:" folder.

Consider the following data structures....

```
#define CUR_FIFOFILE_VERSION 0

typedef struct FIFOFileHeader{
    long typeP1,typeP2;          // 'IGOR','fifo'
    long version;                // CUR_FIFOFILE_VERSION
    long datasize; // bytes of data following ChartChunkInfo field if known
    long hsize;    // size of following ChartChunkInfo field; data follows
}FIFOFileHeader;

#define MAX_NOTESIZE 255
#define FIFO_CHAN_VERSION_NUM 0x01

typedef struct ChartChanInfo{
    long ntype;                  // number type -- NT_FP32 or NT_I16 or ...
    double offset,gain;          // result= (measval-offset)*gain
    double fsPlus,fsMinus;      // value of + & - full scale
    char name[MAX_OBJ_NAME+1];  // name of this channel
    char units[4];               // SU abbrev of units
    long chanRefcon;             // for use by data acquisition sw
}ChartChanInfo;

typedef struct ChartChunkInfo{
    long type;                   // 'chrt'
    short version;               // version number of this data structure
    short pad1;                  // maintain 32 bit alignment
    unsigned long startDate;     // datetime of start command
    char note[MAX_NOTESIZE+1];   // room for a short note from user
    double deltaT;               // data acquisition speed (if known,in seconds)
    long xopRefcon;              // for use by data acquisition sw
    long nchan;                  // number of channels
    ChartChanInfo info[];        // info for each channel
}ChartChunkInfo;
```

The FIFO file consists of the FIFOFileHeader followed by the ChartChunkInfo and finally by chunks of data until the end of the file. It is expected that the format of this file will undergo evolutionary changes. You should be prepared to keep up with such changes. In particular you should always check for the proper version numbers when trying to interpret such a file.

Charts

An Igor Chart works in conjunction with a FIFO to display data as it is acquired or to review data that has previously been acquired.

The information provided here pertains to using rather than programming a chart. If you are interested in programming a chart application, you should examine the examples provided by WaveMetrics in the Examples folder.

Chart Basics

An Igor Chart is neither an analytical tool nor a presentation quality graphic. It is meant only for real time monitoring of incoming data or to review data from a FIFO file. When you want an analytical or presentation quality graph you must transfer the data to a wave and then use a conventional Igor graph.

An Igor Chart emulates a mechanical chart recorder that writes on paper with moving pens as the paper scrolls by under the pens. It differs from a real chart recorder in that the paper of the latter moves at a constant velocity whereas the “paper” of an Igor chart moves only when data becomes available in the FIFO it is monitoring. If data is placed in the FIFO at a constant rate then the “paper” will scroll by at a constant rate. However, since there can be no guarantee that the data is coming in at a constant rate, we refer to the horizontal axis not in terms of time but rather in terms of data sample number.

A given chart can monitor an arbitrary selection of channels from a single FIFO. Each chart trace can have its own display gain, color and line style and can either have its own area on the “paper” or can share an area with one or more other traces. There can be multiple charts active at one time in one or more control panel or graph windows.

You create a chart using the **Chart** operation (page V-38). You can obtain information about a given chart using the **ControlInfo** operation (page V-57).

Additional Notes

Charts sometimes try to auto-configure themselves to match their FIFO. Generally this action is exactly what you want and is unobtrusive. Here are the rules that charts use:

When the FIFO becomes invalid or if it ceases to exist then the chart marks itself as being in auto-configure mode. If the FIFO then becomes valid the chart will read the FIFO information and configure itself to monitor all channels. It tries to set the **ppStrip** parameter to a value appropriate for the **deltaT** value of the FIFO. It does so by assuming a desirable update rate of around 10 strips per second. Thus, for example, if **deltaT** was 1 millisecond then **ppStrip** would be set to 100. The moral is: **deltaT** had better be valid or weird values of **ppStrip** may be created.

Any chart channel configuration commands executed after the FIFO becomes invalid but before the FIFO becomes valid again will prevent auto-configuration from taking place.

Background Task

A fairly simple user-defined backgrounding capability is built into Igor Pro. It is somewhat limited but may find some use in data acquisition tasks. As of Igor Pro 6, you can create multiple named background tasks and even preemptive threads. See **CtrlNamedBackground** operation (page V-73) and **ThreadSafe Functions and Multitasking** on page IV-214.

The backgrounder will call a user-defined function at fixed intervals of time. You use the **SetBackground** operation (page V-488) to specify your user-defined function, you use the **CtrlBackground** operation (page V-73) to set the time interval and to start and stop backgrounding, and you use the **BackgroundInfo** operation (page V-27) to get information about the current background task. The **KillBackground** operation (page V-284) removes your task.

Be sure that your user-defined function returns the proper exit code. See **SetBackground** for details.

Example

Here is a simple example of a background task that prints hello to the history once per second for a total of four times. In the command line enter:

```
Variable gHelloCnt=0
```

In the Procedure window, enter:

```
#pragma rtGlobals=1
```

```
Function myHelloFunc()  
    print "hello"  
    NVAR gHelloCnt = gHelloCnt  
    gHelloCnt += 1  
    if( gHelloCnt >= 4 )  
        Print "background task finished"  
        return 1    // Tell Igor to stop background task.  
    endif  
    return 0        // Tell Igor to continue calling background task.  
End
```

Close the procedure window and execute the following:

```
SetBackground myHelloFunc()  
gHelloCnt=0;CtrlBackground period=60,start
```

The background task will print “hello” four times and then turn itself off, by returning a 1 instead of the normal 0.

Remember to put the `return 0` at the end of the function. Otherwise the background task will stop prematurely.

Limitations

The principal limitation of the backgrounder is that the background task is stopped while other operations are taking place or, on the Macintosh, when the mouse button is pressed and held down. Thus, although you can type commands into the command line without disrupting the background task, when you press Return the task is stopped until execution of the command line is finished. Also the presence of an error dialog will temporarily stop the background task. When the task resumes it will often be far behind in its schedule of invocations. The background task will then execute your task as rapidly as possible in an attempt to catch up. You can change this behavior to skip missed task run times using the `noBurst` keyword with the `CtrlBackground` operation.

Your background task will also normally be stopped while an Igor dialog is present. This is to prevent crashes that can occur if your task were to make certain changes that Igor’s dialogs are not prepared to handle. However, if you are certain that your task will be well-behaved (as described below), then you can let your task run while dialogs are present by means of the `CtrlBackground dialogsOK` keyword.

Another problem involves the handling of errors that occur as a result of the background task code. If the error occurs during the execution of a user-defined function then Igor presents an error dialog after the code finishes execution. If this error dialog were presented every time a fast background task executed then the user would be unable to work since a new dialog would be presented as soon as the last was dismissed. For this reason, Igor will present only the first error dialog after the user (a) clicks in a control, (b) executes a command at the command line or (c) runs a macro via a menu. After the first error, all following errors will be redirected to the history area up to a maximum of 10 errors. After that no more errors will be reported. This method of preventing dialog overload only works if the error occurs in a user function.

If an error occurs during execution of a background process that is due to use of the `Execute` command, then background processing will be terminated after the error dialog from `Execute` is dismissed. A short message will be printed in the history.

The background function should normally return the value 0. You can terminate the background task by returning the value 1 from the background function. You can not call SetBackground or KillBackground from your background function. If you do, Igor will print an error message in the history and then terminate your task.

It is very easy to hang your computer using background tasks. If the background task takes a long time to execute or if it triggers something that takes a long time (like a dependent wave equation or updating a complex graph) then it may appear that the system is hung. It is not, but it may take longer to respond to user actions than you are willing to wait.

Background Task Tips

Background tasks should be designed to execute very fast. As mentioned, they are not separate threads and they hang Igor's event processing as long as they run. For maximum responsiveness, your task should never take more than a fraction of a second to run even when the period is long. If you have to perform a lengthy computation, be sure to let the user know what is going on, perhaps via a message in a status control panel.

Background tasks should never attempt to put up dialogs or directly wait for user input. They should just move data around and set or read variables. If you need to get the attention of the user, you should design your system to include a status control panel with an area for messages or some other change in appearance. If you need to wait for the user, you should do so by monitoring global variables set by nonbackground code such as a button procedure in a panel. Your task should always leave the current data folder unchanged on exit.

If you use the CtrlBackground dialogsOK keyword to enable running while an Igor dialog is present, you should ensure that your background task never kills waves or variables. It should never directly modify a window (except for a status panel) and especially should never remove something from a window (such as a trace from a graph).

Background tasks can do their own timing. If the normal timing method is not to your liking, for example if the time between runs is not a constant, then you can use global variables combined with the ticks function to wait until the time is right for another run.

Here is an example that uses the above concepts. The task spits out "Hello from the background, #n" at one second intervals five times, performs a "lengthy calculation" and then waits for the user to give the go-ahead for another run. The task does its own timing and consequently is set to run at the maximum rate (60 times per second if the operating system and hardware support it).

```
#pragma rtGlobals= 1

Function BGDemo()
    DoWindow/F BGDemoPanel          // bring panel to front if it exists
    if( V_Flag != 0 )
        return 0                    // panel already exists
    endif

    String dfSav= GetDataFolder(1) // so we can leave current DF as we found it
    NewDataFolder/O/S root:Packages
    NewDataFolder/O/S root:Packages:MyDemo    // our variables go here

    // still here if no panel, create globals if needed
    if( NumVarOrDefault("inited",0) == 0 )
        Variable/G inited= 1

        Variable/G lastRunTicks= 0 // value of ticks function last time we ran
        Variable/G runNumber= 0    // incremented each time we run
        // message displayed in panel using SetVariable...
        String/G message="Task paused. Click Start to resume."

        Variable/G running=0       // when set, we do our thing
    endif

    SetDataFolder dfSav
    NewPanel /W=(150,50,449,163)
    DoWindow/C BGDemoPanel          // set panel name
    Button StartButton,pos={21,12},size={50,20},proc=BGStartStopProc,title="Start"
    SetVariable msg,pos={21,43},size={300,17},title=" ",frame=0
    SetVariable msg,limits={-Inf,Inf,1},value= root:Packages:MyDemo:message
```

```
    SetBackground MyBGTask()
    CtrlBackground period=1,start
End

Function MyBGTask()
    NVAR running= root:Packages:MyDemo:running

    if( running == 0 )
        return 0 // not running -- wait for user
    endif

    NVAR lastRunTicks= root:Packages:MyDemo:lastRunTicks

    if( (lastRunTicks+60) >= ticks )
        return 0 // not time yet, wait
    endif

    NVAR runNumber= root:Packages:MyDemo:runNumber

        running= 0
        Button $ctrlName,rename=StartButton,title="Start"
        CtrlBackground stop
    endif
End
```

ThreadSafe Functions and Multitasking

Experienced programmers can use **ThreadSafe Functions** (see page IV-66) to improve execution speed on computers with multiple processors and to create preemptive multitasking background tasks. Preemptive multitasking uses the following functions and operations:

ThreadGroupCreate

ThreadGroupWait

ThreadGroupGetDF	ThreadProcessorCount
ThreadGroupPutDF	ThreadReturnValue
ThreadGroupRelease	ThreadStart

To run a ThreadSafe function preemptively, you first create a thread group using **ThreadGroupCreate** and then call **ThreadStart** to start your function. Usually, you will use the same function for each thread of a group although they can be different.

Because the main thread and your preemptive threads have their own exclusive data folder trees, thread groups support a method of passing data using queues. The “currency” of these queues is the data folder, which provides considerable flexibility for passing data to preemptive threads and for retrieving results. Each thread group has an input queue to which the main thread may post data and an output queue from which the main thread may retrieve results.

Use **ThreadGroupPutDF** to post data folders and **ThreadGroupGetDF** to retrieve them. ThreadGroupPutDF clips the specified data folder (and everything it contains) out of the source thread and puts it in the input queue. From the standpoint of the source thread, it is as if KillDataFolder had been called. While a data folder resides in a queue, it is not accessible by any thread. ThreadGroupGetDF stitches the data folder from the queue into the current data folder of the calling thread and gives it a unique name starting with its original name. It is then owned by the calling thread.

You can determine if any threads of a group are still running by calling **ThreadGroupWait**. Use zero for milliseconds to wait to just test or provide a large value to cause the main thread to sleep until the threads are finished. If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don’t return in time.

Once you are finished with a given thread group, call **ThreadGroupRelease**.

The Igor Debugger can not be used with preemptive threads. You will need to use print statements for debugging.

Understanding all the above is the easy part. The hard part is devising a scheme for partitioning your data processing algorithms into threads.

Parallel Processing

In this example, we attempt to improve the speed of filling columns of a 2D wave with a sin function. The traditional method is compared with parallel processing. Notice how much more complicated the multi-threaded version, MTFillWave, is compared to the single threaded STFillWave.

```
ThreadSafe Function MyWorkerFunc(w,col)
    WAVE w
    Variable col

    w[][col]= sin(x/(col+1))

    return stopMSTimer(-2)           // Time when we finished
End

Function MTFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable i,col,nthreads= ThreadProcessorCount
    variable mt= ThreadGroupCreate(nthreads)

    for(col= 0;col<ncol;)
        for(i=0;i<nthreads;i+=1)
            ThreadStart mt,i,MyWorkerFunc(dest,col)
            col+=1
            if( col>=ncol )
                break
            endif
        endfor
    endfor
```

```
        do
            variable tgs= ThreadGroupWait(mt,100)
            while( tgs != 0 )
            endfor
        variable dummy= ThreadGroupRelease(mt)
    End

Function STFillWave(dest)
    WAVE dest

    Variable ncol= DimSize(dest,1)
    Variable col

    for(col= 0;col<ncol;col+=1)
        MyWorkerFunc(dest,col)
    endfor
End

Function ThreadTest(rows)
    Variable rows

    Variable cols=10

    make/o/n=(rows,cols) jack

    Variable i

    for(i=0;i<10;i+=1)        // get any pending pause events out of the way
    endfor

    Variable ttime= stopMSTimer(-2)

    Variable t0= stopMSTimer(-2)
    MTFillWave(jack)
    Variable t1= stopMSTimer(-2)
    STFillWave(jack)
    Variable t2= stopMSTimer(-2)

    ttime= (stopMSTimer(-2) - ttime)*1e-6

    // Times are in microseconds
    printf "ST: %d, MT: %d; ",t2-t1,t1-t0
    printf "speed up factor: %.3g; tot time= %.3gs\r",(t2-t1)/(t1-t0),ttime
End
```

The empty loop above is necessary because of periodic pauses in execution to check for user aborts. If a pause was pending, we want to get it out of the way beforehand to avoid it affecting the first timing test.

After starting Igor Pro, there is initially some extra overhead associated with creating new threads. Consequently, in the test results to follow, the first test is run twice.

Results for Mac Mini 1.66 GHz Core Duo, OS X 10.4.6:

```
•ThreadTest(100)
  ST: 223, MT: 1192; speed up factor: 0.187; tot time= 0.00146s
•ThreadTest(100)
  ST: 211, MT: 884; speed up factor: 0.239; tot time= 0.0011s
•ThreadTest(1000)
  ST: 1991, MT: 1821; speed up factor: 1.09; tot time= 0.00381s
•ThreadTest(10000)
  ST: 19857, MT: 11921; speed up factor: 1.67; tot time= 0.0318s
•ThreadTest(100000)
  ST: 199174, MT: 113701; speed up factor: 1.75; tot time= 0.313s
•ThreadTest(1000000)
  ST: 2009948, MT: 1146113; speed up factor: 1.75; tot time= 3.16s
```

As you can see, when there is sufficient work to be done, the speed up factor approaches the theoretical maximum of 2 for dual processors.

Now on the same computer but booting into Windows XP Pro:

```
•ThreadTest(100)
  ST: 245, MT: 523; speed up factor: 0.468; tot time= 0.000776s
•ThreadTest(100)
  ST: 399, MT: 247; speed up factor: 1.61; tot time= 0.000655s
•ThreadTest(1000)
  ST: 3526, MT: 1148; speed up factor: 3.07; tot time= 0.00468s
```

```

·ThreadTest(10000)
  ST: 34830, MT: 10467; speed up factor: 3.33; tot time= 0.0453s
·ThreadTest(100000)
  ST: 350253, MT: 99298; speed up factor: 3.53; tot time= 0.45s
·ThreadTest(1000000)
  ST: 2837645, MT: 1057275; speed up factor: 2.68; tot time= 3.89s

```

So, what is happening here? The speed-up factors for Windows XP are greater than for Mac OS X, but mostly because the ST version is much slower. We do not know why the ST version runs more slowly — the Benchmark 2.01 example experiment shows similar values for OS X vs. XP on this same computer.

Input/Output Queues

In this example, we create data folders containing a data wave and a string variable, which specifies the task to be performed, and then post them to a thread group. We use a different data folder for output although you can also simply reuse the input data folder.

ThreadSafe Function MyWorkerFunc()

```

do
  do
    String tdf= ThreadGroupGetDF(0,1000)
    if( strlen(tdf) == 0 )
      print "Worker thread still waiting for input queue."
    else
      break
    endif
  while(1)

  SetDataFolder tdf
  SVAR todo
  WAVE jack
  SetDataFolder ::

  NewDataFolder/S outDF
  Duplicate jack,outw // WARNING: outw must be cleared. See WAVECclear below
  String/G did= todo
  if( CmpStr(todo,"sin") )
    outw= sin(outw)
  else
    outw= cos(outw)
  endif

  // Clear outw so Duplicate above does not try to use it and to allow put.
  WAVECclear outw
  ThreadGroupPutDF 0,:

  KillDataFolder tdf // We are done with the input data folder

while(1)
return 0
End

```

```

Function TestThreadQueue()
  Variable i,ntries= 5,nthreads= 2

  variable/G tgID= ThreadGroupCreate(nthreads)

  for(i=0;i<nthreads;i+=1)
    ThreadStart tgID,i,MyWorkerFunc()
  endfor

  for(i=0;i<ntries;i+=1)
    NewDataFolder/S forThread
    String/G todo
    if( mod(i,3) == 0 )
      todo= "sin"
    else
      todo= "cos"
    endif
    Make/N= 5 jack= x + gnoise(0.1)

    WAVECclear jack
  endfor
endfunction

```

```
        ThreadGroupPutDF tgID,:
    endfor

    for(i=0;i<ntries;i+=1)
        do
            String tdf= ThreadGroupGetDF(tgID,1000)
            if( strlen(tdf) == 0 )
                print "Main still waiting for worker thread results."
            else
                break
            endif
        while(1)
            SetDataFolder tdf
            SVAR did
            WAVE outw

            print "task= ",did,"results= ",outw

            KillDataFolder :
        endfor

        Variable tstatus= ThreadGroupRelease(tgID)
        if( tstatus == -2 )
            print "Thread would not quit normally, had to force kill it. Time to restart."
        endif
    End
End
```

Typical output:

```
·TestThreadQueue()
  task=   sin  results=
outw[0]= {0.994567,0.660904,-0.516692,-0.996884,-0.63106}
  task=   cos  results=
outw[0]= {0.0786631,0.709576,0.873524,0.0586175,-0.718122}
  task=   cos  results=
outw[0]= {-0.23686,0.848603,0.871922,0.0992451,-0.856209}
  task=   sin  results=
outw[0]= {0.999734,0.531563,-0.172071,-0.931296,-0.750942}
  task=   cos  results=
outw[0]= {-0.166893,0.767707,0.925874,0.114511,-0.662994}
  worker thread still waiting for input queue
  worker thread still waiting for input queue
```

Preemptive Background Task

In this example, we create a single worker thread that runs while the user can do other things. A normal cooperative named background task will retrieve results. Although the named task will sometimes be blocked (as described in **Background Task** on page IV-211) the preemptive worker thread will always be running or waiting for data.

We put the code for the background tasks in an independent module (see **The IndependentModule Pragma** on page IV-40) so that the user can recompile procedures, which is done automatically when a recreation macro is created.

One use for a preemptive background task is when you have lengthy computations but want to continue to do other things, such as creating graphics for publication. Although you can do anything you want while the task runs in the experiment, if you load a different experiment, the thread will be killed.

Our “lengthy computation” is simply creating a wave of sin values but which is prolonged by code delays of a few seconds before posting the results. The named background task checks the output queue every 10 ticks (when it is not blocked) and updates a graph with data retrieved from the queue.

Copy the following code to a new procedure window (not the main procedure window):

```
#pragma IndependentModule= PreemptiveExample

ThreadSafe Function MyWorkerFunc()

    do
        String tdf= ThreadGroupGetDF(0,inf)
        if( strlen(tdf) == 0 )
```

```

        return -1                // Thread is being killed
    endif

    SetDataFolder tdf
    WAVE Kenith                  // Array of frequencies to calculate
    SetDataFolder ::

    Variable i, n= numpnts(Kenith)
    for(i=0;i<n;i+=1)

        NewDataFolder/S resultsDF
        Make jack= sin(Kenith[i]*x)

        Variable t0= ticks
        do
            // waste cpu for a few seconds
            while(ticks < (t0+120))

                WAVEClear jack      // Must have no references to allow put.

                ThreadGroupPutDF 0,:
            endwhile
        endfor

        KillDataFolder tdf        // We are done with the input data folder
    while(1)

    return 0
End

```

```

Function myResultsFunc(s)
    STRUCT WMBackgroundStruct &s

    String dfSav= GetDataFolder(1)

    SetDataFolder root:testdf
    NVAR tgID
    String tdf= ThreadGroupGetDF(tgID,0)
    if( strlen(tdf) != 0 )
        SetDataFolder tdf
        WAVE jack                // this is the output from the thread
        AppendToGraph/W=ThreadResultsGraph jack
    endif

    SetDataFolder dfSav
    return 0
End

```

And copy this function to the main procedure window:

```

Function TestThreadQueue()
    String dfSav= GetDataFolder(1)

    NewDataFolder/O/S root:testdf// thread group ID and result datafolders go here
    variable/G tgID= ThreadGroupCreate(1)

    ThreadStart tgID,0,PreemptiveExample#MyWorkerFunc()

    // MyWorkerFunc is now running and waiting for input data
    // now, let's give it something to do
    NewDataFolder/S tasks
    Make/N=5 Kenith= 1/(10+p/2+enoise(0.2)) // array of frequencies to calculate
    WAVEClear Kenith

    ThreadGroupPutDF tgID,:// thread is now crunching away

    Display as "output"
    DoWindow/C ThreadResultsGraph      // results will be appended here...

    // ...by this named task
    CtrlNamedBackground myResultsTask,period=10,proc=PreemptiveExample#myResultsFunc,start

    SetDataFolder dfSav                // be a good citizen and restore current df
End

Function PostMoreFreqs()
    NVAR tgID= root:testdf:tgID

```

```
NewDataFolder/S moretasks
Make/N=50 Kenith= 1/(15+p/2+enoise(0.2))// array of frequencies to calculate
WAVEClear Kenith

ThreadGroupPutDF tgID, :           // thread continues crunching
End
```

Once the code is compiled, on the command line execute

```
TestThreadQueue( )
```

After the action stops, send more tasks to the background thread by executing

```
PostMoreFreqs( )
```

While this is running, experiment with creating graphs, using dialogs, creating functions, etc. Note that both tasks run indefinitely. If you want to start over, you will need to stop the threads and kill the graph.

Cursors — Moving Cursor Calls Function

Note: The following section “The Old Easy Way” is now outdated as of Igor Pro 5 (though it still works). Use the **SetWindow** operation (page V-504) hook and the **cursormoved** event instead. The window hook isolates handling the cursor to the graph window in which the cursor is moving, and is no more difficult to program than the old global **CursorMovedHook** which is called for cursors moving in any graph window.

The Old Easy Way

You can write a “hook function” — which must be named “**CursorMovedHook**” — and Igor will automatically call it with one string argument containing information about the graph, trace or image, and cursor in the following format:

```
GRAPH:graphName;CURSOR:<A - J>;TNAME:traceName; MODIFIERS:modifierNum;
ISFREE:freeNum;POINT:xPointNumber; [YPOINT:yPointNumber;]
```

The **CursorMovedHook** function is called whenever any cursor is moved in any graph, unless Option (*Macintosh*) or Alt (*Windows*) is held down.

The *traceName* value is the name of the graph trace or image to which it is attached or which supplies the x (and y) values.

The *modifierNum* value represents the state of some of the keyboard keys summed together:

- 1 If Command (*Macintosh*) or Ctrl (*Windows*) is pressed.
- 2 If Control (*Macintosh only*) is pressed.
- 4 If Shift is pressed.
- 8 If Caps Lock is pressed.

The Option key (*Macintosh*) or Alt key (*Windows*) is not represented because it prevents the hook from being called.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in **Cursor** operation on page V-76). If TNAME is empty, fields POINT, ISFREE and YPOINT are not present.

This example hook function simply prints the information in the history window:

```
Function CursorMovedHook(info)
    String info
    Print info
End
```

Whenever any cursor on any graph is moved, this **CursorMovedHook** function will print something like the following in the history area:

GRAPH:Graph0;CURSOR:A;TNAME:jack;MODIFIERS:0;ISFREE:0;POINT:6;

See **Example Cursor Global User Function** on page IV-222 for a more sophisticated use of this info string.

The Hard Way

It is also possible to use Igor's dependency mechanism to cause functions to execute automatically when the user moves cursors on a given graph. The advantage of this method is that the function(s) are specific to the given graph.

To do this, create a data folder named WinGlobals and within that create a data folder of the same name as the desired graph. Within that data folder create a string variable named S_CursorAInfo or S_CursorBInfo.

Cursor Globals

If these variables exist (and if Option (*Macintosh*) or Alt (*Windows*) is not held down), then when the user moves a cursor, Igor will set them to an informational string in the following format (all one line):

```
GRAPH:graphName;CURSOR:<A - J>;TNAME:traceName;MODIFIERS:modifierNum;
ISFREE:freeNum;POINT:xPointNumber;[YPOINT:yPointNumber;]
```

Moving cursor A, for example, will update S_CursorAInfo. If the cursor is being removed, traceName will be zero length.

Creating the Cursor Globals

Here is code that creates the necessary global variables for the top graph:

```
Function CursorGlobalsForGraph()
    String graphName= WinName(0,1)
    if( strlen(graphName) )
        String df= GetDataFolder(1);
        NewDataFolder/O root:WinGlobals
        NewDataFolder/O/S root:WinGlobals:$graphName
        String/G S_CursorAInfo, S_CursorBInfo
        SetDataFolder df
    endif
End
```

And code that deletes the globals:

```
Function RemoveCursorGlobals()
    String graphName= WinName(0,1)
    if( strlen(graphName) )
        KillDataFolder root:WinGlobals:$graphName
    endif
End
```

(You can arrange for RemoveCursorGlobals() to be called automatically when Graph0 is closed by setting the "window hook function" of Graph0. See the **SetWindow** operation.)

Establishing a Dependency Between Cursor Globals and a User Function

For a user-defined function to be automatically called when, for example, you move the A cursor for Graph0, you must establish a dependency involving the global WinGlobals:Graph0:S_CursorAInfo and the user-defined function.

This example establishes a dependency between additional variables and each of the cursor info globals involving the example user function shown in the next section (CursorMoved). This dependency updates WinGlobals:Graph0:dependentA by CursorMoved whenever S_CursorAInfo is changed due to cursor A being moved (and likewise for dependentB and S_CursorBInfo):

```
Function CursorDependencyForGraph()
    String graphName= WinName(0,1)
```

```

    if( strlen(graphName) )
        String df= GetDataFolder(1);
        NewDataFolder/O root:WinGlobals
        NewDataFolder/O/S root:WinGlobals:$graphName
        String/G S_CursorAInfo, S_CursorBInfo
        Variable/G dependentA
        SetFormula dependentA, "CursorMoved(S_CursorAInfo, 0)"
        Variable/G dependentB
        SetFormula dependentB, "CursorMoved(S_CursorBInfo, 1)"
        SetDataFolder df
    endif
End

```

Example Cursor Global User Function

The example user function takes two arguments. Yours must have at least one: the cursor info string that Igor automatically updates when the cursor is moved.

Inside the user function, you can parse the cursor info parameter with the **StringByKey** (page V-602) and **NumberByKey** (page V-404) functions. You can obtain additional information about the cursor using the usual routines such as `hcsr` and `vcsr`.

In almost all cases, the top graph will be the one referenced by the info string. However, it is possible to write a user function that moves the cursors and then brings a different graph to the top before your dependency fires. Therefore it is possible (though unlikely) that calling a routine like `hcsr` could generate an error if you don't first check that the top graph is the one referenced in the info string. (You can use `DoWindow/F graphName` to ensure that the graph is top-most.)

This simple example prints to the history area the value of a five-point average around the new cursor position whenever the cursor moves:

```

Function CursorMoved(info, isB)
    String info
    Variable isB          // 0 if A cursor, nonzero if B cursor

    Variable result= NaN  // error result
    // Check that the top graph is the one in the info string.
    String topGraph= WinName(0,1)
    String graphName= StringByKey("GRAPH", info)
    if( CmpStr(graphName, topGraph) == 0 )
        // If the cursor is being turned off
        // the trace name will be zero length.
        String tName= StringByKey("TNAME", info)
        if( strlen(tName) ) // cursor still on
            String cn
            Variable xVal
            if( isB )
                xVal= hcsr(B)
                cn= "Cursor B"
            else
                xVal= hcsr(A)
                cn= "Cursor A"
            endif
            // compute the local 5-point mean
            WAVE w= TraceNameToWaveRef(graphName, tName)
            Variable pointNum= NumberByKey("POINT", info)
            Variable x1= pnt2x(w, pointNum-2)
            Variable x2= pnt2x(w, pointNum+2)
            result= mean(w, x1, x2)
            Print cn+ " on "+tName+" moved to x= ", xVal, "mean= ", result
        endif
    endif
End

```

```
    return result  
End
```

The Result

Whenever either cursor on Graph0 is moved, the CursorMoved function will print something like the following in the history area:

```
Cursor A on wave0#1 moved to x= 33 mean= 0.0239056
```

Igor Reference

This volume contains detailed information about Igor Pro's built-in operations, functions, and keywords. They are listed alphabetically after the category sections that follow.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser.

Alphabetic Listing of Functions, Operations and Keywords

This section alphabetically lists all built-in functions, operations and keywords. Much of this information is also accessible online in the Command Help tab of the Igor Help Browser.

External operations (XOPs) and external functions (XFUNCs) are not covered here. For information about them, use the Command Help tab of the Igor Help Browser and the XOP help file in the same folder as the XOP file.

Reference Syntax Guide

In the descriptions of functions and operations that follow, italics indicate parameters for which you can supply numeric or string expressions. Nonitalic parameters are to be entered literally as they appear. Commas, slashes, braces and parentheses in these descriptions are always literals. Bold brackets may also be literals; they are used to specify point ranges or indices (the description will make this clear).

Nonbold brackets surround optional flags or parameters.

Ellipses (...) indicate that the preceding element may be repeated a number of times. The exact number of repetitions varies, and should be found in the description.

Italicized parameters represent values you supply. Italic words ending with “*Name*” are names (wave names, for example), and those ending with “*Str*” (and the words “*string*” or “*str*”) are strings. Some Igor functions can take an empty string (“ ”, no space between the quotation marks) as a parameter. Italic words ending with “*Spec*” (meaning “specification”) are usually further defined in the description. If none of these endings are employed, the italic word is a numeric expression, such as a literal number, the name of a variable or function, or some valid combination.

Strings and names are different, but you can use a string where a name is expected using “string substitution”: precede a string expression with the \$ operator. See **String Substitution Using \$** on page IV-14.

A syntax description may span several lines, but the actual command you create must occupy a single line. Igor has no line continuation character like FORTRAN programs or Unix command shells.

Many operations have optional “flags”. Flags that accept a value (such as the Make operation’s /N=*n* flag) sometimes require additional parentheses. For example:

```
Make/N=1 aNewWave
```

is acceptable because here *n* is the literal “1”. To use a numeric expression for *n*, parentheses are needed:

```
Make/N=(numberOfPoints) aNewWave // error if no parentheses!
```

And, yes, the use of just one variable constitutes an “expression”!

Some operations have multiple forms. The syntax for each is shown on a separate line.

For more about using functions, operations and keywords, see Chapter IV-1, **Working with Commands**, Chapter IV-2, **Programming Overview**, and Chapter IV-10, **Advanced Programming**.

define

define

#define *symbol*

The #define statement is a conditional compilation directive that defines a *symbol* for use only with #ifdef or #ifndef expressions. #undef removes the definition.

Details

The defined *symbol* exists only in the file where it is defined; the only exception is in the main procedure window where the scope covers all other procedures except independent modules. See **Conditional Compilation** on page IV-68 for information on defining a global *symbol*.

#define cannot be combined inline with other conditional compilation directives.

See Also

The #undef, #ifdef-#endif, and #ifndef-#endif statements; and **Conditional Compilation** on page IV-68 for more usage details.

if-# elif-# endif

```
#if expression1  
  <TRUE part 1>  
#elif expression2  
  <TRUE part 2>  
[...]  
[#else  
  <FALSE part>]  
#endif
```

In a #if-#elif-#endif conditional compilation statement, when an expression evaluates as TRUE (absolute value > 0.5), then only code corresponding to the TRUE part of that expression is compiled, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is compiled when present.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

See Also

Conditional Compilation on page IV-68 for more usage details.

if-# endif

```
#if expression  
  <TRUE part>  
[#else  
  <FALSE part>]  
#endif
```

A #if-#endif conditional compilation statement evaluates *expression*. If *expression* is TRUE (absolute value > 0.5) then the code in *TRUE part* is compiled, or if FALSE (zero) then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

See Also

Conditional Compilation on page IV-68 for more usage details.

ifdef-# endif

```
#ifdef symbol  
  <TRUE part>  
[#else  
  <FALSE part>]  
#endif
```

A #ifdef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is defined the code in *TRUE part* is compiled, or if undefined then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

symbol must be defined before the conditional with #define.

See Also

The #define statement and **Conditional Compilation** on page IV-68 for more usage details.

#ifndef-#endif

```
#ifndef symbol
    <TRUE part>
[#else
    <FALSE part>]
#endif
```

An #ifndef-#endif conditional compilation statement evaluates *symbol*. When *symbol* is undefined the code in *TRUE part* is compiled, or if defined then the optional *FALSE part* is compiled.

Details

Conditional compiler directives must be either entirely outside or inside function definitions; they cannot straddle a function fragment. Conditionals cannot be used within Macros.

symbol must be defined before the conditional with #define.

See Also

The #define statement and **Conditional Compilation** on page IV-68 for more usage details.

#include

```
#include "file spec" or <file spec>
```

A #include statement in a procedure file automatically opens another procedure file. You should use #include in any procedure file that you write if it requires that another procedure file be open. A #include statement must always appear flush against the left margin in a procedure window.

Parameters

file spec is the procedure file name, which can incorporate a full or partial path. The form used depends of the procedure file location: <*file spec*> is in the WaveMetrics Procedures folder and "*file spec*" is in the User Procedures folder.

See Also

The **Include Statement** on page IV-119 for usage details.

#pragma

```
#pragma [rtGlobals = 0, 1, or 2][IgorVersion = versNum]
        [version = versNum][ModuleName = name]
        [IndependentModuleName = name]
```

#pragma introduces a compiler directive, which is a message to the Igor procedure compiler. A #pragma statement must always appear flush against the left margin in a procedure window.

See Also

rtGlobals, **IgorVersion**, **IndependentModule**, **ModuleName**, and **version** for details about these particular #pragma directives. Also see **Silent** and **Pragmas** on page IV-39.

#undef

```
#undef symbol
```

A #undef statement removes a nonglobal *symbol* created previously by #define. See **Conditional Compilation** on page IV-68 for information on undefining a global *symbol*.

See Also

The #define statement and **Conditional Compilation** on page IV-68 for more usage details.

Abort

Abort [*errorMessageStr*]

The Abort operation aborts procedure execution.

Parameters

The optional *errorMessageStr* is a string expression, which, if present, specifies the message to be displayed in the error alert.

Details

Abort provides a way for a procedure to abort execution when it runs into an error condition.

See Also

Aborting Functions on page IV-71 and **Aborting Macros** on page IV-85. The **DoAlert** operation.

AbortOnRTE

AbortOnRTE

The AbortOnRTE flow control keyword raises an abort with a runtime error. AbortOnRTE should be used after an operation that might give rise to a runtime error. It has very low overhead and should not significantly slow program execution.

Details

In terms of programming style, you should consider using AbortOnRTE (preceded by a semicolon) on the same line as the command that may give rise to an abort condition.

When using AbortOnRTE after a related sequence of commands, then it should be placed on its own line.

Example

Abort if the wave does not exist:

```
WAVE someWave; AbortOnRTE
```

See Also

Flow Control for Aborts on page IV-37 and **AbortOnRTE Keyword** on page IV-37 for further details.

The **try-catch-endtry** flow control statement.

AbortOnValue

AbortOnValue *abortCondition*, *abortCode*

The AbortOnValue flow control keyword will abort function execution when the *abortCondition* is nonzero and it will then return the numeric *abortCode*. No dialog will be displayed when such an abort occurs.

Parameters

abortCondition can be any valid numeric expression using comparison or logical operators.

abortCode is a nonzero numeric value returned to any abort or error handling code by AbortOnValue whenever it causes an abort.

See Also

Flow Control for Aborts on page IV-37 and **AbortOnValue Keyword** on page IV-37 for further details.

The **AbortOnRTE** keyword and the **try-catch-endtry** flow control statement.

abs

abs (*num*)

The abs function returns the absolute value of the real number *num*. To calculate the absolute value of a complex number, use the cabs function.

See Also

The **cabs** function.

acos

acos (num)

The acos function returns the inverse cosine of *num* in radians. In complex expressions, *num* is complex and acos returns a complex value.

acosh

acosh (num)

The acosh function returns the inverse hyperbolic cosine of *num*. In complex expressions, *num* is complex and acosh returns a complex value.

AddFIFOData

AddFIFOData FIFOName, FIFO_channelExpr [, FIFO_channelExpr]...

The AddFIFOData operation evaluates *FIFO_channelExpr* expressions as double precision floating point and places the resulting values into the named FIFO.

Details

There must be one *FIFO_channelExpr* for each channel in the FIFO.

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-208.

Other operations used with FIFOs: **NewFIFO**, **NewFIFOChan**, **CtrlFIFO**, and **FIFOStatus**.

AddFIFOVectData

AddFIFOVectData FIFOName, FIFO_channelKeyExpr [, FIFO_channelKeyExpr]...

The AddFIFOVectData operation is similar to AddFIFOData except the expressions use a keyword to allow either a single numeric value for a normal channel or a wave containing the data for a special image vector channel.

Details

There must be one *FIFO_channelKeyExpr* for each channel in the FIFO.

A *FIFO_channelKeyExpr* may be one of:

num = *numericExpression*

vect = *wave*

For best results, the wave should have the same number of points as used to define the FIFO channel and the same number type. See the **NewFIFOChan** operation.

See Also

FIFOs and Charts on page IV-208.

AddListItem

AddListItem(itemStr, listStr [, listSepStr [, itemNum]])

The AddListItem function returns *listStr* after adding *itemStr* to it. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use AddListItem to add an item to a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or to a line from a delimited text file.

listSepStr and *itemNum* are optional; their defaults are ";" and 0, respectively.

Details

By default *itemStr* is added to the start of the list. Use the optional list index *itemNum* to add *itemStr* at a different location. The returned list will have *itemStr* at the index *itemNum* or at *ItemsInList(returnedListStr)-1* when *itemNum* equals or exceeds *ItemsInList(listStr)*.

itemNum can be any value from -infinity (-Inf) to infinity (Inf). Values from -infinity to 0 prepend *itemStr* to the list, and values from *ItemsInList(listStr)* to infinity append *itemStr* to the list.

itemStr may be "", in which case an empty item (consisting of only a separator) is added.

AddMovieAudio

If *listSepStr* is "", then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case the empty string is returned).

listStr is treated as if it ends with a *listSepStr* even if it doesn't.

Only the first character of *listSepStr* is used.

Examples

```
Print AddListItem("hello","kitty;cat;")           // prints "hello;kitty;cat;"
Print AddListItem("z", "b,c", "", "", 1)          // prints "b,z,c,"
Print AddListItem("z", "b,c", "", "", 999)         // prints "b,c,z,"
Print AddListItem("z", "b,c", "", "", Inf)         // prints "b,c,z,"
Print AddListItem("", "b-c-", "-")                // prints "-b-c-"
```

See Also

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveFromList**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **VariableList**, and **WaveList** functions.

AddMovieAudio

AddMovieAudio *soundWaveName*

The AddMovieAudio operation adds audio samples to the audio track of the currently open movie.

Parameters

soundWaveName contains audio samples with an amplitude from -128 to +127 and with the same time scale as the prototype *soundWaveName* used to open the movie.

Details

You can create movies with 16-bit and stereo sound by providing a sound wave in the appropriate format. To specify 16-bit sound, the wave type must be signed 16-bit integer (/W flag in **Make** or **Redimension**). To specify stereo, use a wave with two columns (or any other number of channels as desired).

See Also

The **NewMovie** operation.

AddMovieFrame

AddMovieFrame

The AddMovieFrame operation adds the top graph to the currently open movie.

When you write a procedure to generate a movie, you need to call the **DoUpdate** operation after all modifications to the graph and before calling AddMovieFrame. This allows Igor to process any changes you have made to the graph.

See Also

The **NewMovie** operation.

airyA

airyA(*x* [, *accuracy*])

The airyA function returns the value of the Airy $Ai(x)$ function:

$$Ai(x) = \frac{1}{\pi\sqrt{3}} K_1 \left(\frac{2}{3} x^3 \right) \text{ where } K \text{ is the modified Bessel function.}$$

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyAD** and **airyB** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

airyAD

airyAD(x [, accuracy])

The airyAD function returns the value of the derivative of the Airy function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyA** function.

airyB

airyB(x [, accuracy])

The airyB function returns the value of the Airy $Bi(x)$ function:

$$Bi(x) = \sqrt{\frac{x}{3}} \left[I_{-1/3} \left(\frac{2}{3} x^{3/2} \right) + I_{1/3} \left(\frac{2}{3} x^{3/2} \right) \right] \text{ where } I \text{ is the modified Bessel function.}$$

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyBD** and **airyA** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

airyBD

airyBD(x [, accuracy])

The airyBD function returns the value of the derivative $Bi'(x)$ of the Airy function.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **airyB** function.

alog

alog(num)

The alog function returns 10^{num} .

AnnotationInfo

AnnotationInfo(winNameStr, annotationNameStr [, options])

The AnnotationInfo function returns a string containing a semicolon-separated list of information about the named annotation in the named graph or page layout window or subwindow.

The main purpose of AnnotationInfo is to use a tag or textbox as an input mechanism to a procedure. This is illustrated in the "Tags as Markers Demo" sample experiment, which includes handy utility functions (supplied by AnnotationInfo Procs.ipf).

Parameters

winNameStr can be "" to refer to the top graph or layout window or subwindow.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

options is an optional parameter that controls the text formatting in the annotation output. The default value is 0.

Omit *options* or use 0 for *options* to escape the returned annotation text, which is appropriate for printing the output to the history or for using the text in an Execute operation.

Use 1 for *options* to not escape the returned annotation text because you intend to extract the text for use in a subsequent command such as Textbox or Tag.

AnnotationList

Details

The string contains thirteen pieces of information. The first twelve pieces are prefaced by a keyword and colon and terminated with a semicolon. The last piece is the annotation text, which is prefaced with a keyword and a colon but is not terminated with a semicolon.

Keyword	Information Following Keyword
ABSX	X location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ABSY	Y location, in points, of the anchor point of the annotation. For graphs, this is relative to the top-left corner of the graph window. For layouts, it is relative to the top-left corner of the page.
ATTACHX	For tags, it is the X value of the wave at the point where the tag is attached, as specified with the Tag operation. For textboxes, color scales, and legends, this will be zero and has no meaning.
AXISX	X location of the anchor point of the annotation. For tags or color scales in graphs, it is in terms of the X axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first X axis. For layouts, this has no meaning and is always zero.
AXISY	Y location of the anchor point of the annotation. For layouts, this has no meaning and is always zero. For tags or color scales in graphs, it is in terms of the Y axis against which the tagged wave is plotted. For textboxes and legends in graphs, it is in terms of the first Y axis.
AXISZ	Z value of the image or contour level trace to which the tag is attached or NaN if the trace is not a contour level trace or the annotation is not a tag.
COLORSCALE	Parameters used in a ColorScale operation to create the annotation.
FLAGS	Flags used in a Tag, Textbox, ColorScale, or Legend operation to create the annotation.
RECT	The outermost corners of the annotation (values are in points): RECT: <i>left, top, right, bottom</i>
TEXT	Text that defines the contents of the annotation or the main axis label of a color scale.
TYPE	Annotation type: "Tag", "Textbox", "ColorScale", or "Legend".
XWAVE	For tags, it is the name of the X wave in the XY pair to which the tag is attached. If the tag is attached to a single wave rather than an XY pair, this will be empty. For textboxes, color scales, and legends, this will be empty and has no meaning.
XWAVEDF	For tags, the full path to the data folder containing the X wave associated with the trace to which the tag is attached. For textboxes, color scales, and legends, this will be empty and has no meaning.
YWAVE	For tags, it is the name of the trace or image to which the tag is attached. See ModifyGraph (traces) and Instance Notation on page IV-16 for discussions of trace names and instance notation. For color scales, it is the name of the wave displayed in associated the contour plot, image plot, f(z) trace, or the name of the color scale's cindex wave. For textboxes and legends, this will be empty and has no meaning.
YWAVEDF	Full path to the data folder containing the Y wave or blank if the annotation is not a tag or color scale.

AnnotationList

AnnotationList(*winNameStr*)

The AnnotationList function returns a semicolon-separated list of annotation names from the named graph or page layout window or subwindow.

Parameters

winNameStr can be "" to refer to the top graph or layout window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

APMath

APMath [*flags*] *destStr* = *Expression*

The APMath operation provides arbitrary precision calculation of basic mathematical expressions. It converts the final result into the assigned string *destStr*, which can then be printed or used to represent a value (at the given precision) in another APMath operation.

Parameters

destStr Specifies a destination string for the assignment expression. If *destStr* is not an existing variable, it is created by the operation. When executing in a function, *destStr* will be a local variable if it does not already exist.

Expression Algebraic expression containing constants, local, global, and reference variables or strings, as well as wave elements together with the following operators:

Operator	Precedence
^	Highest
* /	
+ -	Lowest

Operators

Supported operators are:

+ Scalar addition.
 - Scalar subtraction.
 * Scalar multiplication.
 / Scalar division.
 ^ Exponentiation.

Functions

The following functions are supported:

sqrt(x) Square root of *x*.
cbrt(x) Cube root of *x*.

pi Value of π . (without parentheses).
sin(x) Sine of *x*.
cos(x) Cosine of *x*.
tan(x) Tangent of *x*.
asin(x) Inverse sine of *x*.
acos(x) Inverse cosine of *x*.
atan(x) Inverse tangent of *x*.
atan2(y, x) Inverse tangent of *y/x*.

log(x) Logarithm of *x*.
log10(x) Logarithm based 10 of *x*.
exp(x) Exponential function e^x .
pow(x, n) *x* to the power *n* (*n* not necessarily integer).
sinh(x) Hyperbolic sine of *x*.
cosh(x) Hyperbolic cosine of *x*.
tanh(x) Hyperbolic tangent of *x*.
asinh(x) Inverse hyperbolic sine of *x*.
acosh(x) Inverse hyperbolic cosine of *x*.
atanh(x) Inverse hyperbolic tangent of *x*.

ceil(x) Smallest integer larger than *x*.

<code>comp(x,y)</code>	Returns 0 for $x == y$, 1 if $x > y$ and -1 if $y > x$.
<code>factorial(n)</code>	Factorial of integer n .
<code>floor(x)</code>	Greatest integer smaller than x .
<code>gcd(x,y)</code>	Greatest common divisor of x and y .
<code>lcd(x,y)</code>	Lowest common denominator of x and y (given by $x*y/gcd(x,y)$).
<code>sgn(x)</code>	Sign of x or zero if $x == 0$.

Flags

<code>/EX=exDigits</code>	Specifies the number of extra digits added to the precision digits (<code>/N</code>) for intermediate steps in the calculation.
<code>/N=numDigits</code>	Specifies the precision of the final result. To add digits to the intermediate computation steps, use <code>/EX</code> .
<code>/V</code>	Verbose mode; prints the result in the history in addition to performing the assignment.
<code>/Z</code>	No error reporting.

Details

By default, all arbitrary precision math calculations are performed with `numDigits=50` and `exDigits=6`, which yields a final result using at least 56 decimal places. Because none of the built-in variable types can express numbers with such high accuracy, the arbitrary precision numbers must be stored as strings. The operation automatically converts between strings and constants. It evaluates all of the numerical functions listed above using the specified accuracy. If you need functions that are not supported by this operation, you may have to precompute them and store the results in a local variable.

The operation stores the result in `destStr`, which may or may not exist prior to execution. When you execute the operation from the command line, `destStr` becomes a global string in the current data folder if it does not already exist. If it exists, then the result of the operation overwrites its value (as with any normal string assignment). In a user function, `destStr` can be a local string, an SVAR, or a string passed by reference. If `destStr` is not one of these then the operation creates a local string by that name.

Arbitrary precision math calculations are much slower (by a factor of about 300) than equivalent floating point calculations. Execution time is a function of the number of digits, so you should use the `/N` flag to limit the evaluation to the minimum number of required digits.

Examples

Evaluate pi to 50 digits:

```
APMath/V aa=pi
```

Evaluate ratios of large factorials:

```
APMath/v aa=factorial(500)/factorial(499)
```

Evaluate ratios of large exponentials:

```
APMath/v aa=exp(-1000)/exp(-1001)
```

Division of mixed size values:

```
APMath/v aa=1-sgn(1-(1-0.00000000000000000001234)/(1-0.000000000000000000012345)))
```

you'll get a different result trying to evaluate this using double precision.

Difference between built-in pi and the arbitrary precision pi:

```
Variable/G biPi=pi
```

```
APMath/v aa=biPi-pi
```

Precision control:

```
Function test()
    APMath aa=pi                // Assign 50 digit pi to the string aa.
    APMath/v bb=aa              // Create local string bb equal to aa.
    APMath/v bb=aa-pi           // Subtract arb. prec. pi from aa.
                                // note the default exDigits=6.
                                // setting exDigits=0.
    APMath/v/n=50/ex=0 bb=aa-pi
End
```

Numerical recreation:

```
APMath/v/n=16 aa=111111111^2
```

Append

Append

The Append operation is interpreted as **AppendToGraph**, **AppendToTable**, or **AppendToLayout**, depending on the target window. This does not work when executing a user-defined function. Therefore we now recommend that you use **AppendToGraph**, **AppendToTable**, or **AppendLayoutObject** rather than Append.

AppendImage

AppendImage [**/G=g/W=winName**][**axisFlags**] **matrix** [**vs {xwaveName, ywaveName}**]

The AppendImage operation appends the matrix as an image to the target or named graph. By default the image is plotted versus the left and bottom axes.

Parameters

matrix is either an NxM matrix for false color or indexed color images or can be a 3D NxMx3 wave containing a layer of data for red, a layer for green and a layer for blue. If matrix contains multiple planes other than three or if it contains 3 planes and multiple chunks, the **ModifyImage** plane keyword can be used to specify the desired subset to display.

If you provide *xwaveName* and *ywaveName*, *xwaveName* provides X coordinate values, and *ywaveName* provides Y coordinate values. This makes an image with uneven pixel sizes. In both cases, you can use * to specify calculated values. See **Details** if you use *xwaveName* or *ywaveName*.

Flags

<i>axisFlags</i>	Flags /L, /R, /B, and /T are the same as used by AppendToGraph .
/G=g	g=1: Suppresses the autodetection of three plane images as direct (RGB) color. g= 0: Same as no /G flag (default).
/W=winName	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

When appending an image to a graph, you can supply optional X and Y waves to define the coordinates of the rectangle edges. *These waves need to contain one more data point than the X (row) or Y (column) dimension of the matrix to define the end of the last rectangle.*

For false color, the values in the matrix are linearly mapped into a color table. See the **ModifyImage ctab** keyword. For indexed color, the values in the matrix are interpreted as Z values to be looked up in a user-supplied 3 column matrix of colors. See the **ModifyImage index** keyword. Direct color NxMx3 waves contain the actual red, green, and blue values for each pixel. If the number type is unsigned bytes, then the range of intensity ranges from 0 to 255. For all other number types, the intensity ranges from 0 to 65535.

By default, nondirect color matrices are initially displayed as false color using the Grays color table and autoscale mode.

If the matrix is complex, the image is displayed in terms of the magnitude of the Z value, that is, $\sqrt{\text{real}^2 + \text{imag}^2}$.

See Also

The **NewImage**, **ModifyImage**, and **RemoveImage** operations. For general information on image plots see Chapter II-15, **Image Plots**.

AppendLayoutObject

AppendLayoutObject [**flags**] **objectType** **objectName**

The AppendLayoutObject operation appends a single object to the top layout or to the layout specified via the /W flag.

Unlike the AppendToLayout operation, AppendLayoutObject can be used in user-defined functions. Therefore, AppendLayoutObject should be used in new programming instead of AppendToLayout.

Parameters

objectType identifies the type of object to be appended. It is one of the following keywords: **graph**, **table**, **picture**.

objectName is the name of the graph, table or picture to be appended.

Use a space between *objectType* and *objectName*. A comma is not allowed.

Flags

<i>/D=fidelity</i>	Draws layout objects in low fidelity (<i>fidelity</i> =0) or high fidelity (<i>fidelity</i> =1; default). This affects drawing on the screen only, not exporting or printing. Low fidelity is somewhat faster but less accurate and should be used only for graphs that take a very long time to draw.
<i>/F=frame</i>	Specifies the type of frame enclosing the object. <i>frame</i> =0: None. <i>frame</i> =1: Single frame (default). <i>frame</i> =2: Double frame. <i>frame</i> =3: Triple frame. <i>frame</i> =4: Shadow frame.
<i>/T=trans</i>	Sets the transparency of the object background to opaque (<i>trans</i> =0; default) or transparent (<i>trans</i> =1). For transparency to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque. Opaque PICTs cannot be made transparent.
<i>/R=(l, t, r, b)</i>	Sets the size and position of the object. If omitted, the object is placed with a default size and position. <i>l</i> , <i>t</i> , <i>r</i> , and <i>b</i> are the left, top, right, and bottom coordinates of the object, respectively. Coordinates are expressed in units of points, relative to the top/left corner of the paper.
<i>/W=winName</i>	Appends the object to the named page layout window. If <i>/W</i> is omitted or if <i>winName</i> is \$" ", the top page layout is used.

See Also

NewLayout, **ModifyLayout**, **RemoveLayoutObjects**, **TextBox**, and **Legend**.

AppendMatrixContour

AppendMatrixContour [*axisFlags*] [*/F=formatStr* */W=winName*] *zWave*
[*vs {xWave, yWave}*]

The **AppendMatrixContour** operation appends to the target or named graph a contour plot of a matrix of *z* values with autoscaled contour levels, using the Rainbow color table.

Note: There is no **DisplayContour** operation. Use **Display**; **AppendMatrixContour**.

Parameters

zWave must be a matrix (2D wave).

To contour a set of XYZ triplets, use **AppendXYZContour**.

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns. This results in an "uneven grid" of Z values.

If you omit the *xWave* and *yWave* specification, Igor uses the *zWave*'s X and Y scaled indices as the X and Y values. Igor also uses the *zWave*'s scaled indices if you use * (asterisk symbol) in place of *xWave* or *yWave*.

In a procedure, to modify the appearance of contour levels before the contour is calculated and displayed with the default values, append **;**DelayUpdate**** and immediately follow the **AppendMatrixContour** command with the appropriate **ModifyContour** commands. All but the last **ModifyContour** command should also have **;**DelayUpdate**** appended.

On the command line, the **Display** command and following **AppendMatrixContour** and **ModifyContour** commands can be typed all on one line with semicolons between:

Display; **AppendMatrixContour** *MyMatrix*; **ModifyContour** ...

Flags

axisFlags Flags /L, /R, /B, /T are the same as used by **AppendToGraph**.

/F=*formatStr* Determines the names assigned to the contour level traces. See **Details**.

/W=*winName* Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

AppendMatrixContour creates and displays contour level traces. You can modify these all together using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will not need to modify the individual traces.

By default, Contour level traces are automatically named with names that show the *zWave* and the contour level, for example, "zWave=1.5". You will see these trace names in the Modify Trace Appearance dialog and in Legends. In most cases, the default trace names will be just fine.

If you want to control the names of the contour level traces (which you might want to do for names in a Legend), use the /F=*formatStr* flag. This flag uses a format string as described for the **printf** operation. The default format string is "% .17s=%g", resulting in trace names such as "zWave=1.5". *formatStr* must contain at least %f or %g (used to insert the contour level) or %d (used to insert the zero-based index of the contour level). Include %s, to insert the *zWave* name.

Here are some examples of format strings.

<i>formatStr</i>	Examples of Resulting Name	Format
"%g"	"100", "1e6", "-2.05e-2"	(<level>)
"z=%g"	"z=100", "z=1e6", "z=-2.05e-2"	(z=<level>)
"%s %f"	"zWave 100.000000"	(<wave>, space, <level>)
"[%d]=%g"	"[0]=100", "[1]=1e6"	([<index>]=<level>)

Examples

```
Make/O/N=(25,25) w2D           // Make a matrix
SetScale x -1, 1, w2D         // Set row scaling
SetScale y -1, 1, w2D         // Set column scaling
w2D = sin(x) * cos(y)         // Store values in the matrix
Display; AppendMatrixContour w2D; DelayUpdate
ModifyContour w2D autoLevels={*,*,9} // roughly 9 automatic levels
```

See also

AppendToGraph for details about other axis flags. The **AppendXYZContour**, **ModifyContour**, and **RemoveContour** operations. For general information on contour plots, see Chapter II-14, **Contour Plots**.

AppendText

AppendText [/W=*winName*/N/**NOCR** [=n]] *textStr*

The AppendText operation appends a carriage return and *textStr* to the most recently created or changed annotation, or to the named annotation in the target or graph or layout window. Annotations include tags, textboxes, color scales, and legends.

Parameters

textStr can contain escape codes to control font, font size and other stylistic variations.

Flags

/N=*name* Appends *textStr* to the named tag or textbox.

/NOCR[=*n*] Omits the initial appending of a carriage return (allows a long line to be created with multiple AppendText commands). /NOCR=0 is the same as no /NOCR, and /NOCR=1 is the same as just /NOCR.

/W=*winName* Appends to an annotation in the named graph, layout window, or subwindow. Without /W, AppendText appends to an annotation in the topmost graph or layout

AppendToGraph

window or subwindow. This must be the first flag specified when AppendText is used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

A textbox, tag, or legend can contain at most 100 lines. A color scale can have at most one line, and this line is the color scale's main axis label.

See Also

The **Tag**, **TextBox**, **ColorScale**, **ReplaceText**, and **Legend** operations.

AppendToGraph

AppendToGraph [*flags*] *waveName* [, *waveName*]...[*vs xwaveName*]

The AppendToGraph operation appends the named waves to the target or named graph. By default the waves are plotted versus the left and bottom axes.

Parameters

The *waveNames* parameters are the names of existing waves.

vs xwaveName plots the data values of *waveNames* against the data values of *xwaveName*.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-267.

Flags

/B [=axisName]	Plots X coordinates versus the standard or named bottom axis.
/C=(<i>r,g,b</i>)	<i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color of the appended waves as an integer from 0 to 65535.
/L [=axisName]	Plots Y coordinates versus the standard or named left axis.
/Q	Uses a special, quick update mode when appending to a pair of existing axes. A side effect of this mode is that waves that are appended are marked as not modified. This will prevent other graphs containing these waves, if any, from being updated properly.
/R [=axisName]	Plots Y coordinates versus the standard or named right axis.
/T [=axisName]	Plots X coordinates versus the standard or named top axis.
/VERT	Plots data vertically. Similar to SwapXY (ModifyGraph (axes)) but on a trace-by-trace basis.
/W= <i>winName</i>	Appends to the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also

The **Display** operation.

AppendToLayout

AppendToLayout [*flags*] *objectSpec* [, *objectSpec*]...

The AppendToLayout operation appends the specified objects to the top layout.

The AppendToLayout operation can not be used in user-defined functions. Use the AppendLayoutObject operation instead.

Parameters

The optional *objectSpec* parameters identify a graph, table, textbox or PICT to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See the **Layout** operation for details.

Flags

/G=g	Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.
/I	<i>objectSpec</i> coordinates are in inches.
/M	<i>objectSpec</i> coordinates are in centimeters.
/R	<i>objectSpec</i> coordinates are in percent of printing part of the page.
/S	Stacks objects.
/T	Tiles objects.

See Also

The **Layout** and **AppendLayoutObject** operations for use with user-defined functions.

AppendToTable

AppendToTable [/W=*winName*] *columnSpec* [, *columnSpec*]...

The AppendToTable operation appends the specified columns to the top table. *columnSpecs* are the same as for the **Edit** operation; usually they are just the names of waves.

Flags

/W= <i>winName</i>	Appends columns to the named table window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
--------------------	--

See Also

Edit for details about *columnSpecs*, and **RemoveFromTable**.

AppendXYZContour

AppendXYZContour [/W=*winName* /F=*formatStr*][*axisFlags*] *zWave* [vs {*xWave*, *yWave*}]

The AppendXYZContour operation appends to the target or named graph a contour of a 2D wave consisting of XYZ triples with autoscaled contour levels and using the Rainbow color table.

To contour a matrix of Z values, use **AppendMatrixContour**.

Note: There is no DisplayContour operation. Use **Display; AppendXYZContour**.

Parameters

If you provide the *xWave* and *yWave* specification, *xWave* provides X values for the rows, and *yWave* provides Y values for the columns, *zWave* provides Z values and all three waves must be 1D. All must have at least four rows and must have the same number of rows.

If you omit the *xWave* and *yWave* specification, *zWave* must be a 2D wave with 4 or more rows and 3 or more columns. The first column is X, the second is Y, and the third is Z. Any additional columns are ignored.

If any of X, Y, or Z in a row is blank, (NaN), that row is ignored.

To modify the appearance of contour levels before the contour is calculated and displayed with the default values, append **;DelayUpdate** and immediately follow the AppendXYZContour command with the appropriate **ModifyContour** commands. All but the last **ModifyContour** command should also have **;DelayUpdate** appended

On the command line, the **Display** command and subsequent AppendXYZContour commands and any **ModifyContour** commands can be typed all on one line with semicolons between:

Display; AppendXYZContour MyMatrix; ModifyContour ...

Flags

<i>axisFlags</i>	Flags /L, /R, /B, and /T are the same as used by AppendToGraph .
/F= <i>formatStr</i>	Determines names assigned to the contour level traces. This is the same as for AppendMatrixContour .
/W= <i>winName</i>	Appends to the named graph window or subwindow. When omitted, action affects the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

AppendXYZContour creates and displays contour level traces. You can modify these as a group using the Modify Contour Appearance dialog or individually using the Modify Trace Appearance dialog. In most cases, you will have no need to modify the traces individually.

See **AppendMatrixContour** for a discussion of how the contour level traces are named.

Examples

```
Make/O/N=(100) xW, yW, zW          // Make X, Y, and Z waves
xW = sawtooth(2*PI*p/10)          // Generate X values
yW = trunc(p/10)/10              // Generate Y values
zW = sin(2*PI*xW)*cos(2*PI*yW)    // Generate Z values
Display; AppendXYZContour zW vs {xW, yW}; DelayUpdate
ModifyContour zW autoLevels={*,*,9} // roughly 9 automatic levels
```

area

area(waveName [, x1, x2])

The area function returns the signed area between the named wave and the line $y=0$ from $x=x1$ to $x=x2$ using trapezoidal integration, accounting for the wave's X scaling. If your data are in the form of an XY pair of waves, see **areaXY**.

Details

If $x1$ and $x2$ are not specified, they default to $-\infty$ and $+\infty$, respectively.

If $x1$ or $x2$ are not within the X range of *waveName*, area limits them to the nearest X range limit of *waveName*.

If any values in the X range are NaN, area returns NaN.

Reversing the order of $x1$ and $x2$ changes the sign of the returned area.

The area operation is intended to work on 1D waves only.

Examples

```
Make/O/N=100 data; SetScale/I x 0, Pi, data
data=sin(x)
Print area(data, 0, Pi)          // the entire X range, and no more
Print area(data)                 // same as -infinity to +infinity
Print area(data, Inf, -Inf)      // +infinity to -infinity
```

The following is printed to the history area:

```
·Print area(data, 0, Pi)          // the entire X range, and no more
  1.99983
·Print Print area(data)           // same as -infinity to +infinity
  1.99983
·Print area(data, Inf, -Inf)      // +infinity to -infinity
 -1.99983
```

The $-\text{Inf}$ value was limited to 0 and Inf was limited to Pi to keep them within the X range of data.

See Also

The figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

The **Integrate** operation.

For XY data, see **areaXY**.

areaXY

areaXY(XWaveName, YWaveName [, x1, x2])

The areaXY function returns the signed area between the named *YWaveName* and the line $y=0$ from $x=x1$ to $x=x2$ using trapezoidal integration with X values supplied by *XWaveName*.

This function is identical to the **area** function except that it works on an XY wave pair.

Details

If $x1$ and $x2$ are not specified, they default to $-\infty$ and $+\infty$, respectively.

If $x1$ or $x2$ are outside the X range of *XWaveName*, areaXY limits them to the nearest X range limit of *XWaveName*.

If any Y values in the specified X range are NaN, areaXY returns NaN.

Reversing the order of $x1$ and $x2$ changes the sign of the returned area.

If $x1$ or $x2$ are not found in *XWaveName*, a Y value is found by linear interpolation based on the two bracketing X values and the corresponding values from *YWaveName*.

The values in *XWaveName* may be increasing or decreasing. AreaXY assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

See the figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

The areaXY operation is intended to work on 1D waves only.

Examples

```
Make/O/N=101 Xdata, Ydata
Xdata = x*pi/100
Ydata = sin(Xdata[p])
Print areaXY(Xdata, Ydata,0,Pi)           // the entire X range, and no more
Print areaXY(Xdata, Ydata)                // same as -infinity to +infinity
Print areaXY(Xdata, Ydata,Inf,-Inf)       // +infinity to -infinity
```

The following is printed to the history area:

```
•Print areaXY(Xdata, Ydata,0,Pi)           // the entire X range, and no more
  1.99984
•Print areaXY(Xdata, Ydata)                // same as -infinity to +infinity
  1.99984
•Print areaXY(Xdata, Ydata,Inf,-Inf)       // +infinity to -infinity
 -1.99984
```

The -Inf value was limited to 0, and Inf was limited to Pi to stay within the X range of data.

See Also

The **Integrate** operation and the **area**, **faverage**, **faverageXY**, and **PolygonArea** functions.

asin

asin(*num*)

The asin function returns the inverse sine of *num* in radians. In complex expressions, *num* is complex, and asin returns a complex value.

asinh

asinh(*num*)

The asinh function returns the inverse hyperbolic sine of *num*. In complex expressions, *num* is complex, and asinh returns a complex value.

atan

atan(*num*)

The atan function returns the inverse tangent of *num* in radians. In complex expressions, *num* is complex, and atan returns a complex value. Results are in the range $-\pi/2$ to $\pi/2$.

atan2

atan2(*y1*, *x1*)

The atan2 function returns the angle in radians whose tangent is $y1/x1$. Results are in the range $-\pi$ to π .

atanh

atanh(*num*)

The atanh function returns the inverse hyperbolic tangent of *num*. In complex expressions, *num* is complex, and atanh returns a complex value.

AutoPositionWindow

AutoPositionWindow [/E/M=m/R=relWindow] [*windowName*]

The AutoPositionWindow operation positions the window specified by *windowName* relative to the next lower window of the same kind or relative to the window given by the /R flag. If *windowName* is not specified, AutoPositionWindow acts on the target window.

Flags

/E	Uses entire area of the monitor. Otherwise, it takes into account the command window.
/M= <i>m</i>	Specifies the window positioning method.
<i>m</i> =0:	Positions <i>windowName</i> to the right of the other window, if possible. If there is no room, then it positions <i>windowName</i> just below the other window but at the left edge of the display area. If that is not possible, then the position is not affected.
<i>m</i> =1:	Positions <i>windowName</i> just under the other window lined up on the left edge, if possible. If there is no room, then it positions <i>windowName</i> just to the right of the other window lined up on the bottom edges. If neither are possible then it positions <i>windowName</i> as far to the bottom and right as it will go.
/R= <i>relWindow</i>	Positions <i>windowName</i> relative to <i>relWindow</i> .

AxisInfo

AxisInfo(*graphNameStr*, *axisNameStr*)

The AxisInfo function returns a string containing a semicolon-separated list of information about the named axis in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

axisNameStr is the name of the graph axis.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

Keyword	Information Following Keyword
AXFLAG	Flag used to select the axis in any of the operations that display waves (Display, AppendMatrixContour, AppendImage, etc.).
AXTYPE	Axis type, such as "left", "right", "top", or "bottom".
CATWAVE	Wave supplying the categories for the axis if this is a category plot.
CATWAVEDF	Full path to data folder containing category wave.
CWAVE	Name of wave controlling named axis.
CWAVEDF	Full path to data folder containing controlling wave.
HOOK	Name set by ModifyFreeAxis with hook keyword.
ISCAT	Truth that this is a category axis (used in a category plot).
ISTFREE	Truth that this is truly free axis (created via NewFreeAxis).
MASTERAXIS	Name set by ModifyFreeAxis with master keyword.
RECREATION	List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: <i>keyword</i> (<i>x</i>)= <i>modifyParameters</i> ;
SETAXISCMD	Full SetAxis command.

Keyword	Information Following Keyword
SETAXISFLAGS	Flags that would be used with the SetAxis function to set the particular auto-scaling behavior that the axis uses. If the axis uses a manual axis range, SETAXISFLAGS is blank.
UNITS	Axis units, if any.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword up to the “;”, prepend “ModifyGraph”, replace the “x” with the name of an actual axis and then **Execute** the resultant string as a command.

Examples

```
Make/O data=x;Display data
Print StringByKey("CWAVE", AxisInfo("", "left"))           // prints data
```

See Also

The **StringByKey** and **NumberByKey** functions and the **SetAxis** operation. The #include <Readback ModifyStr> procedures are useful for parsing strings returned by AxisInfo.

AxisList

AxisList(*graphNameStr*)

The AxisList function returns a semicolon-separated list of axis names from the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Examples

```
Make/O data=x;Display/L/T data
Print AxisList("")           // prints left;top;
```

AxisValFromPixel

AxisValFromPixel(*graphNameStr*, *axNameStr*, *pixel*)

The AxisValFromPixel function returns an axis value corresponding to the local graph pixel coordinate in the graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is “left” or “bottom” then the first vertical or horizontal axis will be used. Sources for *pixel* value may be the GetWindow operation or a user window hook with the mousemoved and mousedown event messages (see the **SetWindow** operation).

See Also

The **PixelFromAxisVal** and **TraceFromPixel** functions; the **GetWindow** and **SetWindow** operations.

BackgroundInfo

BackgroundInfo

The BackgroundInfo operation returns information about the current background task.

Details

Information is returned via the following variables:

V_flag	0:	No background task is defined.
	1:	Background task is defined, but not running (is idle).
	2:	Background task is defined and is running.
V_period		DeltaTicks value set by CtrlBackground. This is how often the background task runs.

Beep

v_nextRun Ticks value when the task will run again. 0 if the task is not scheduled to run again.
S_value Text of the numeric expression that the background task executes, as set by `SetBackground`.

See Also

The **SetBackground**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and the **ticks** function. See **Background Task** on page IV-211 for usage details.

Beep

Beep

The Beep operation plays the current alert sound (*Macintosh*) or the system beep sound (*Windows*).

Besseli

Besseli(*n*, *z*)

The Besseli function returns the modified Bessel function of the first kind, $I_n(z)$, of order *n* and argument *z*. Replaces the `bessI` function, which is supported for backwards compatibility only.

If *z* is real, Besseli returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besselj**, **Besselk**, and **Bessely** functions.

Besselj

Besselj(*n*, *z*)

The Besselj function returns the Bessel function of the first kind, $J_n(z)$, of order *n* and argument *z*. Replaces the `bessJ` function, which is supported for backwards compatibility only.

If *z* is real, Besselj returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselk**, and **Bessely** functions.

Besselk

Besselk(*n*, *z*)

The Besselk function returns the modified Bessel function of the second kind, $K_n(z)$, of order *n* and argument *z*. Replaces the `bessK` function, which is supported for backwards compatibility only.

If *z* is real, Besselk returns a real value, which means that if *z* is also negative, it returns NaN unless *n* is an integer.

For complex *z* a complex value is returned, and there are no restrictions on *z* except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional orders *n*, as well as real or complex arguments *z*.

See Also

The **Besseli**, **Besselj**, and **Bessely** functions.

Bessely

Bessely(*n*, *z*)

The Bessely function returns the Bessel function of the second kind, $Y_n(z)$, of order n and argument z . Replaces the `bessY` function, which is supported for backwards compatibility only.

If z is real, Bessely returns a real value, which means that if z is also negative, it returns NaN unless n is an integer. For complex z a complex value is returned, and there are no restrictions on z except for possible overflow.

Details

The calculation is performed using the SLATEC library. The function supports fractional and negative orders n , as well as real or complex arguments z .

See Also

The **Besseli**, **Besselj**, and **Besselk** functions.

bessI

bessI(*n*, *x* [, *algorithm* [, *accuracy*]])

Obsolete — use **Besseli**.

The `bessI` function returns the modified Bessel function of the first kind, $I_n(x)$ of order n and argument x .

For real x , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order n is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If x is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order n can be fractional, and must be real.

Details

The *algorithm* parameter has three options, each selecting a different calculation method:

Algorithm	What You Get
0 (default)	<p>Uses a calculation method that has fractional accuracy better than 10^{-6} everywhere and is generally better than 10^{-8}. This method does not handle fractional order n; the order is truncated to an integer before the calculation is performed.</p> <p>Algorithm 0 is fastest by a large margin.</p>
1	<p>Allows fractional order. The calculation is performed using methods described in <i>Numerical Recipes in C</i>, 2nd edition, pp. 240-245.</p> <p>Using algorithm 1, <i>accuracy</i> specifies the fractional accuracy that you desire. That is, if you set <i>accuracy</i> to $1e-7$ (that is, 10^{-7}), that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$ be better than 10^{-7}. Asking for less accuracy gives some increase in speed.</p> <p>You pay a heavy price for higher accuracy or fractional order. When <i>algorithm</i> is nonzero, calculation time is increased by an order of magnitude for small x; at larger x the penalty is even greater.</p> <p>If <i>accuracy</i> is greater than 10^{-8} and n is an integer, algorithm 0 is used.</p> <p>The algorithm calculates <code>bessI</code> and <code>bessK</code> simultaneously. Both values are stored, and if a call to <code>bessI</code> is followed by a call to <code>bessK</code> (or <code>bessK</code> is followed by <code>bessI</code>) with the same n, x, and <i>accuracy</i> the previously-stored value is returned, making the second call very fast.</p>
2	<p>Fractional order is allowed. The calculation is performed using code from the SLATEC library. The accuracy achievable is often better than algorithm 1, but not always. Algorithm 2 is 1.5 to 3 times faster than algorithm 1, but still slower than algorithm 0. The <i>accuracy</i> parameter is ignored.</p>

The achievable accuracy of algorithms 1 and 2 is a complicated function n and x . To see a summary of achievable accuracies choose File→Example Experiments→Testing and Misc→Bessel Accuracy menu item.

bessJ**bessJ(*n*, *x* [, *algorithm* [, *accuracy*]])**Obsolete — use **Besselj**.

The **bessJ** function returns the Bessel function of the first kind, $J_n(x)$ of order n and argument x .

For real x , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order n is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If x is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order n can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for **bessJ** and **bessY** are calculated simultaneously. The values are stored, and a subsequent call to **bessY** after a call to **bessJ** (or vice versa) with the same n , x , and *accuracy* will be very fast.

bessK**bessK(*n*, *x* [, *algorithm* [, *accuracy*]])**Obsolete — use **Besselk**.

The **bessK** function returns the modified Bessel function of the second kind, $K_n(x)$ of order n and argument x .

For real x , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order n is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If x is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order n can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for **bessJ** and **bessY** are calculated simultaneously. The values are stored, and a subsequent call to **bessY** after a call to **bessJ** (or vice versa) with the same n , x , and *accuracy* will be very fast.

bessY**bessY(*n*, *x* [, *algorithm* [, *accuracy*]])**Obsolete — use **Bessely**.

The **bessY** function returns the Bessel function of the second kind, $Y_n(x)$ of order n and argument x .

For real x , the optional parameter *algorithm* selects between a faster, less accurate calculation method and slower, more accurate methods. In addition, when *algorithm* is zero or absent, the order n is truncated to an integer.

When *algorithm* is included and is 1, *accuracy* can be used to specify the desired fractional accuracy. See Details about algorithms.

If x is complex, a complex result is returned. In this case, *algorithm* and *accuracy* are ignored. The order n can be fractional, and must be real.

Details

See the **bessI** function for details on algorithms, accuracy and speed of execution.

When *algorithm* is 1, pairs of values for **bessJ** and **bessY** are calculated simultaneously. The values are stored, and a subsequent call to **bessY** after a call to **bessJ** (or vice versa) with the same n , x , and *accuracy* will be very fast.

beta

beta(a, b)

The beta function returns for real or complex arguments $\text{Gamma}(a)\text{Gamma}(b)/\text{Gamma}(a+b)$ with $\text{Re}(a), \text{Re}(b) > 0$.

See Also

The **gamma** function.

betai

betai(a, b, x [, accuracy])

The betai function returns the regularized incomplete beta function $I_x(a,b)$, where $a, b > 0$, and $0 \leq x \leq 1$. Optionally, *accuracy* can be used to specify the desired fractional accuracy.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7} , that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$ be less than 10^{-7} .

Larger values of *accuracy* (poorer accuracy) result in evaluation of fewer terms of a series, which means the function executes somewhat faster.

A single-precision level of accuracy is about 3×10^{-7} , double-precision is about 2×10^{-16} . The betai function will return full double-precision accuracy for small values of *a* and *b*. Achievable accuracy declines as *a* and *b* increase:

<i>a</i>	<i>b</i>	<i>x</i>	betai	Accuracy Achievable
1	1.5	0.5	0.646447	2×10^{-16} (full double precision)
8	10	0.5	0.685470	6×10^{-16}
20	21	0.5	0.562685	2×10^{-15}
20	21	0.1	1.87186×10^{-10}	5×10^{-15}

BinarySearch

BinarySearch(waveName, val)

The BinarySearch function performs a binary search of the one-dimensional *waveName* for the value *val*. BinarySearch returns an integer point number *p* such that *waveName*[*p*] and *waveName*[*p*+1] bracket *val*. If *val* is in *waveName*, then *waveName*[*p*]==*val*.

Details

BinarySearch is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

WaveName must contain monotonically increasing or decreasing values.

BinarySearch returns -1 if *val* is not within the range of values in the wave, but would numerically be placed before the first value in the wave.

BinarySearch returns -2 if *val* is not within the range of values in the wave, but would fall after the last value in the wave.

BinarySearch returns -3 if the wave has zero points.

Examples

```
Make/O data = {1, 2, 3.3, 4.9}           // Monotonic increasing
Print BinarySearch(data,3)               // Prints 1
// BinarySearch returns 1 because data[1] <= 3 < data[2].

Make/O data = {9, 4, 3, -6}             // Monotonic decreasing
Print BinarySearch(data,2.5)             // Prints 2
// BinarySearch returns 2 because data[2] >= 2.5 > data[3].
Print BinarySearch(data,10)              // Prints -1, precedes first value
Print BinarySearch(data,-99)             // Prints -2, beyond last value
```

See Also

The **BinarySearchInterp** and **FindLevel** operations. See **Indexing and Subranges** on page II-81.

BinarySearchInterp

BinarySearchInterp(*waveName*, *val*)

The BinarySearchInterp function performs a binary interpolated search of the named wave for the value *val*. The returned value, *pt*, is a floating-point point index into the named wave such that *waveName*[*pt*] == *val*.

Details

BinarySearchInterp is useful for finding the point in an XY pair that corresponds to a particular X coordinate.

WaveName must contain monotonically increasing or decreasing values.

When the named wave does not actually contain the value *val*, BinarySearchInterp locates a value below *val* and a value above *val* and uses reverse linear interpolation to figure out where *val* would fall if a straight line were drawn between them. It includes that fractional amount in the resulting point index.

BinarySearchInterp returns NaN if *val* is not within the range of values in the wave.

Examples

```
Make/O data = {1, 2, 3.3, 4.9}           // Monotonic increasing
Print BinarySearchInterp(data,3)          // Prints 1.76923
Print data[1.76923]                      // Prints 3
Make/O data = {9, 4, 3, 1}               // Monotonic decreasing
Print BinarySearchInterp(data,2.5)        // Prints 2.25
Print data[2.25]                         // Prints 2.5
```

See Also

The **BinarySearch** and **FindLevel** operations. See **Indexing and Subranges** on page II-81.

binomial

binomial(*n*, *k*)

The binomial function returns the ratio:

$$\frac{n!}{k!(n-k)!}.$$

It is assumed that *n* and *k* are integers and $0 \leq k \leq n$ and ! denotes the factorial function.

Note that although the binomial function is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over 2^{52} (about 4.5×10^{15}) will be accurate to about one part in 2×10^{16} .

binomialln

binomialln(*a*, *b*)

The binomialln function returns the natural log of the binomial coefficient for *a* and *b*.

$$\text{binomialln}(a,b) = \ln(a!) - \ln(b!) - \ln((a-b)!)$$

See Also

Chapter III-12, **Statistics** for an overview of the various functions and operations; **binomial**, **StatsBinomialPDF**, **StatsBinomialCDF**, and **StatsInvBinomialCDF**.

binomialNoise

binomialNoise(*n*, *p*)

The binomialNoise function returns a pseudo-random value from the binomial distribution

$$f(x) = \binom{n}{x} p^x (1-p)^{n-x}, \quad \begin{matrix} 0 \leq p \leq 1 \\ x = 1, 2, \dots, n \end{matrix}$$

whose mean is *np* and variance is *np*(1-*p*).

When *n* is large such that p^n is zero to machine accuracy the function returns NaN. When *n* is large such that $np(1-p) > 5$ and $0.1 < p < 0.9$ you can replace the binomial variate with a normal variate with mean *np* and standard deviation $\text{sqrt}(n * p * (1-p))$.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat the same sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

Chapter III-12, **Statistics** for an overview of the various functions and operations; **SetRandomSeed**.

boundingBall

boundingBall [/F/Z] *tripletWave*

The boundingBall operation calculates a bounding sphere for a set of X, Y, Z triplets. This operation accepts waves that have three or more columns; data in any additional columns are ignored.

Parameters

tripletWave is a three-column two-dimensional wave with X coordinates in column 0, Y in column 1, and Z in column 2.

Flags

- /F Uses the algorithm from “An Efficient Bounding Sphere” by Jack Ritter in *Graphics Gems*. This algorithm is less accurate but it produces a ball that is sufficiently large to contain all the points.
- /Z No error reporting.

Details

The center and radius of the bounding sphere are stored in the variables: V_CenterX, V_CenterY, V_CenterZ, and V_Radius.

If you are not using the /F flag, the operation also accepts a 2 column wave consisting of X, Y pairs for calculating the center and radius of a bounding circle in the plane.

References

Glassner, Andrew S., (Ed.), *Graphics Gems*, 833 pp., Academic Press, San Diego, 1990.

break

break

The break flow control keyword immediately terminates execution of a loop, switch, or strswitch. Execution then continues with code following the loop, switch, or strswitch.

See Also

Break Statement on page IV-36, **Switch Statements** on page IV-33, and **Loops** on page IV-34 for usage details.

BrowseURL

BrowseURL [/Z] *urlStr*

The BrowseURL operation opens the Web browser or FTP browser on your computer and asks it to display a particular Web page or to connect to an FTP server.

BrowseURL sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an error occurs.

Parameters

urlStr specifies a Web page or FTP server directory to be browsed. It is constructed of a naming scheme (e.g., “http://” or “ftp://”), a computer name (e.g., “www.wavemetrics.com” or “ftp.wavemetrics.com” or “38.170.234.2”), and a path (e.g., “/Test/TestFile1.txt”). See **Examples** for sample usage.

Flags

- /Z Errors are not fatal. Will not abort procedure execution if the URL is bad or if the server is down. Your procedure can inspect the V_flag variable to see if the transfer succeeded. V_flag will be zero if it succeeded or nonzero if it failed.
Syntactic errors, such as omitting the URL altogether or omitting quotes, are still fatal.

Examples

```
// Browse a Web page.
String url = "http://www.wavemetrics.com/News/index.html"
BrowseURL url

// Browse an FTP server.
String url = "ftp://ftp.wavemetrics.com/pub/test"
BrowseURL url
```

BuildMenu

BuildMenu *menuNameStr*

The BuildMenu operation rebuilds the user-defined menu items in the specified menu the next time the user clicks in the menu bar.

Parameters

menuNameStr is a string expression containing a menu name.

Details

Call BuildMenu when you've defined a custom menu using string variables for the menu items. After you change the string variables, call BuildMenu to update the menu.

Under the current implementation, Igor will rebuild *all* user-defined menus if BuildMenu is called for *any* user-defined menu.

See Also

Dynamic Menu Items on page IV-91.

Button

Button [/Z] *ctrlName* [*key = value*][, *key [= value]*]...

The Button operation creates or modifies the named button control.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

name is the name of the Button control to be created or changed.

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind=default: Appearance determined by **DefaultGuiControls**.

kind=native: Creates standard-looking controls for the current computer platform.

kind=os9: Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows).

platform=Mac: Changes the appearance of controls only on Macintosh; affects the experiment whenever it is used on Macintosh.

platform=Win: Changes the appearance of controls only on Windows; affects the experiment whenever it is used on Windows.

platform=All: Changes the appearance on both Macintosh and Windows computers.

disable=*d* Sets the state of the control. *d* is a bit field: bit 0 (the least significant bit) is set when the control is hidden. Bit 1 is set when the control is disabled:

d=0: Normal (visible), enabled.

d=1: Hidden.

d=2: Visible and disabled. Drawn in grayed state, also disables action procedure.

d=3: Hidden and disabled.

See the **ModifyControl** example for setting the bits individually.

fColor=(*r,g,b*) Sets color of the button. *r*, *g*, and *b* are integers from 0 to 65535. To set the color of the title text, use escape sequences as described below for title.

font="*fontName*" Sets button font, e.g., font="Helvetica".

fsize=*s* Sets font size.

<code>fstyle=<i>fs</i></code>	Specifies the font style. <i>fs</i> is a binary coded number with each bit controlling one aspect of the font style: bit 0: Sold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>). See Setting Bit Parameters on page IV-11 for details about bit settings.
<code>help={<i>helpStr</i>}</code>	Specifies the help for the control. Help text is limited to a total of 255 characters. On Macintosh, help appears if you turn Igor Tips on. On Windows, help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting “\r” in a quoted string.
<code>noproc</code>	No procedure is executed when clicking the button.
<code>picture=<i>pict</i></code>	Draws the button using the named picture. The picture is taken to be three side-by-side frames that show the control appearance in the normal state, when the mouse is down, and in the disabled state. The picture may be either a global (imported) picture or a Proc Picture (see Proc Pictures on page IV-44). The size keyword is ignored when a picture is used.
<code>pos={<i>left,top</i>}</code>	Sets button position in pixels.
<code>proc=<i>procName</i></code>	Names the procedure to execute when clicking the button.
<code>rename=<i>newName</i></code>	Gives the button a new name.
<code>size={<i>width,height</i>}</code>	Sets <i>width</i> and <i>height</i> of button in pixels.
<code>title=<i>titleStr</i></code>	Sets title of button (text that appears in the button) to the specified string expression. If not given then title will be “New”. If you use “ ” the button will contain no text. <i>titleStr</i> can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the TextBox operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired, click the To Cmd Line button, and then edit the TextBox command for use with the control.
<code>userdata(<i>UDName</i>)=<i>UDStr</i></code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional (<i>UDName</i>) to specify a named user data to create.
<code>userdata(<i>UDName</i>)+=<i>UDStr</i></code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional (<i>UDName</i>) to append to the named <i>UDStr</i> .
<code>win=<i>winName</i></code>	Specifies which window or subwindow contains the named button control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The action procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName) : ButtonControl
    String ctrlName
    ...
End
```

The “: ButtonControl” style puts the procedure in the Procedure pop-up menu in the Button Control dialog.

The action procedure for a Button control can also use a predefined structure **WMBUTTONACTION** as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a Button control, otherwise it will use the old-style method.

ButtonControl

A Button action procedure using a structure has the format:

```
Function newActionProcName(B_Struct)
    STRUCT WMButtonAction &B_Struct
    ...
End
```

For a Button control, the WMButtonAction structure has members as follows:

WMButtonAction Structure Members		
Member	Description	
char ctrlName[MAX_OBJ_NAME+1]	Control name.	
char win[MAX_WIN_PATH+1]	Host (sub)window.	
STRUCT Rect winRect	Local coordinates of host window.	
STRUCT Rect ctrlRect	Enclosing rectangle of the control.	
STRUCT Point mouseLoc	Mouse location.	
Int32 eventCode	Event that executed the procedure.	
	eventCode	Event
	-1	Control being killed
	1	Mouse down
	2	Mouse up
	3	Mouse up outside control
	4	Mouse moved
	5	Mouse enter
	6	Mouse leave
	Events 2 and 3 only happen after event 1. Events 4, 5, and 6 happen only when mouse is over the control but happen regardless of the mouse button state.	
Int32 eventMod	Bitfield of modifiers. See description of MODIFIERS : flags for SetWindow under Unnamed Hooks on page V-505.	
String userdata	Primary (unnamed) user data. If this changes, it is written back automatically.	

Action functions should respond only to documented eventCode values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

See Also

The ControlInfo operation for information about the control. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data.

ButtonControl

ButtonControl

ButtonControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined button control. See Procedure Subtypes on page IV-149 for details.

cabs

cabs (z)

The cabs function returns the real-valued absolute value of complex number z.

See Also

The magsqr function.

CaptureHistory

CaptureHistory(refnum, stopCapturing)

The CaptureHistory function returns a string containing text from the History window since a matching call to the **CaptureHistoryStart** function.

Parameters

refnum is a number returned from a call to CaptureHistoryStart. It identifies the starting point in the history for the returned string.

Set *stopCapturing* to nonzero to indicate that no more history should be captured for the given refnum. Subsequent calls to CaptureHistory with the same *refnum* will result in an error.

Set *stopCapturing* to zero to retrieve history text captured so far. Further calls to CaptureHistory with the same reference number will return this text, plus any additional history text added subsequently.

Details

You can have multiple captures active at one time. Each call to CaptureHistoryStart will return a unique reference number identifying a start point in the history. The capture corresponding to each reference number can be terminated at any time, regardless of the order of the CaptureHistoryStart calls.

CaptureHistoryStart

CaptureHistoryStart()

The CaptureHistoryStart function returns a reference number to identify a starting point in the History window text. Subsequently, the CaptureHistory function can be used to retrieve captured history text. See **CaptureHistory** for details.

catch

catch

The catch flow control keyword defines the beginning of code in a try-catch-entry flow control construct for handling any abort conditions.

See Also

The **try-catch-endtry** flow control statement for details.

ceil

ceil(num)

The ceil function returns the closest integer greater than or equal to *num*.

See Also

The **round**, **floor**, and **trunc** functions.

cequal

cequal(z1, z2)

The cequal function determines the equality of two complex numbers *z1* and *z2*. It returns 1 if they are equal, or 0 if not.

This is in contrast to the == operator, which compares only the real components of *z1* and *z2*, ignoring the imaginary components.

Examples

```
Function TestComplexEqualities()
    Variable/C z1= cmplx(1,2), z2= cmplx(1,-2)
    // This test compares only the real parts of z1 and z2:
    if( z1 == z2 )
        Print "== match"
    else
        Print "no == match"
    endif
    // This test compares both real and imaginary parts of z1 and z2:
    if( cequal(z1,z2) )
        Print "cequal match"
    else
```

```
        Print "no cequal match"
    endif
End
·TestComplexEqualities()
    == match
    no cequal match
```

See Also

The **imag**, **real**, and **cmplx** functions.

char2num

char2num(*str*)

The char2num function returns a number which is the ASCII code for the first character in the string expression *str*.

Examples

```
Print char2num("A")           // prints 65
Print char2num("ABC")         // prints 65
```

Chart

Chart [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The Chart operation creates or modifies a chart control. Charts are generally used in conjunction with data acquisition. Charts do not have to be connected to a FIFO, but they are not useful until they are.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the Chart control to be created or changed.

key is one of the following parameters:

chans={ <i>ch#</i> , <i>ch#</i> , ...}	List of FIFO channel numbers that Chart is to monitor.
color(<i>ch#</i>)=(<i>r</i> , <i>g</i> , <i>b</i>)	Sets the color of the specified trace. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color as an integer from 0 to 65535.
ctab= <i>colortableName</i>	When a channel is connected to an image strip FIFO channel, the data is displayed as an image using this built-in color table. Valid names are the same as used in images. Invalid name will result in the default Grays color table being used.
disable= <i>d</i>	Sets user editability of the control. <i>d</i> =0: Normal. <i>d</i> =1: Hide. <i>d</i> =2: Disable user input. Charts do not change appearance because they are read-only. When disabled, the hand cursor is not shown.
fbkRGB=(<i>r</i> , <i>g</i> , <i>b</i>)	Sets frame background color. <i>r</i> , <i>g</i> and <i>b</i> are integers from 0 to 65535.
fgRGB=(<i>r</i> , <i>g</i> , <i>b</i>)	Sets foreground color (text, etc.). <i>r</i> , <i>g</i> and <i>b</i> are integers from 0 to 65535
fifo= <i>FIFOName</i>	Sets which named FIFO the chart will monitor. See the NewFIFO operation.
font=" <i>fontName</i> "	Sets the font used in the chart, e.g., font="Helvetica".
fsize= <i>s</i>	Sets font size for chart.
fstyle= <i>fs</i>	Specifies the font style. <i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>). See Setting Bit Parameters on page IV-11 for details about bit settings.
gain(<i>ch#</i>)= <i>g</i>	Sets the display gain <i>g</i> of the specified channel relative to nominal. Values greater than unity expand the display.

<code>gridRGB=(<i>r,g,b</i>)</code>	Sets grid color. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>help={<i>helpStr</i>}</code>	Specifies help for the control. Help text is limited to a total of 255 characters. On Macintosh, help appears if you turn Igor Tips on. On Windows, help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting “\r” in a quoted string.
<code>jumpTo=<i>p</i></code>	Jumps to point number <i>p</i> . This works in review mode only.
<code>lineMode(<i>ch#</i>)=<i>lm</i></code>	Sets the display line mode for the given channel. <i>lm</i> =0: Dots mode. Draws values as dots. However, if the number of dots in a strip exceeds <code>maxDots</code> then Igor draws a vertical line from the min to the max of the values packed into the strip. <i>lm</i> =1: Lines mode. Draws a vertical line encompassing the min and the max of the points in a given strip along with the last point of the preceding strip. Since which strip is the preceding strip depends on the direction of motion then the appearance may slightly shift depending on which direction the chart is moving. <i>lm</i> =2: Sticks to zero mode. Draws a vertical line encompassing the min and the max of the points in a given strip along with a value of zero.
<code>mass=<i>m</i></code>	Sets the “feel” of the chart paper when you move it with the mouse. The larger the mass <i>m</i> , the slower the chart responds. Odd values cause the movement of the paper to stop the instant the mouse is clicked while even values continue with the illusion of mass.
<code>maxDots=<i>md</i></code>	Controls whether points in a given vertical strip of the chart are displayed as dots or as a solid line. See <code>lineMode</code> above. Default is 20.
<code>offset(<i>ch#</i>)=<i>o</i></code>	Sets the display offset of the specified channel. The offset value <i>o</i> is subtracted from the data before the gain is applied.
<code>oMode=<i>om</i></code>	Chart operation mode. <i>om</i> =0: Live mode. <i>om</i> =1: Review mode.
<code>pbkRGB=(<i>r,g,b</i>)</code>	Sets plot area background color. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>ppStrip=<i>pps</i></code>	Number of data points packed into each vertical strip of the chart.
<code>rSize(<i>ch#</i>)=<i>rs</i></code>	Sets the relative vertical size allocated to the given channel. Nominal is unity. If the value of <i>rs</i> is zero then this channel shares space with the previous channel.
<code>sMode=<i>sm</i></code>	Status line mode. <i>sm</i> =0: Turns off fancy status line and positioning bar. <i>sm</i> =1: Normal mode. <i>sm</i> =2: Uses alternate style for bar.
<code>sRate=<i>sr</i></code>	Sets the scroll rate (vertical strips/second). If the chart control is in review mode negative numbers scroll in reverse.
<code>title=<i>titleStr</i></code>	Specifies the chart title. Use " " for no title.
<code>uMode=<i>um</i></code>	Selects the update mode. <i>um</i> =1: Fast update with no bells and whistles. <i>um</i> =2: Status line and positioning bar. <i>um</i> =3: Status line, positioning bar, and animated pens.
<code>win=<i>winName</i></code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The action of some of the Chart keywords depends on whether or not data acquisition is taking place. If the chart is in review mode then all keywords cause the chart to be redrawn. If data acquisition is taking place and the chart is in live mode then some keywords affect new data but do not attempt to update the part of the "paper" that has already been drawn. The following keywords affect only new data during live mode:

ppStrip maxDots gain offset color lineMode

chebyshev

chebyshev(n, x)

The chebyshev function returns the Chebyshev polynomial of the first kind and of degree n .

The Chebyshev polynomials satisfy the recurrence relation:

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \text{ with: } T_0(x) = 1$$

$$T_1(x) = x$$

$$T_2(x) = 2x^2 - 1$$

The orthogonality of the polynomial is expressed by the integral:

$$\int_{-1}^1 \frac{T_n(x)T_m(x)}{\sqrt{1-x^2}} dx = \begin{cases} 0 & m \neq n \\ \pi & m = n \neq 0 \\ \pi & m = n = 0 \end{cases}.$$

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

See Also

chebyshevU.

chebyshevU

chebyshevU(n, x)

The chebyshevU function returns the Chebyshev polynomial of the second kind, degree n and argument x .

The Chebyshev polynomial of the second kind satisfies the recurrence relation

$$U(n+1, x) = 2xU(n, x) - U(n-1, x)$$

which is also the recurrence relation of the Chebyshev polynomials of the first kind.

The first 10 polynomials of the second kind are:

$$U(0, x) = 1$$

$$U(1, x) = 2x$$

$$U(2, x) = 4x^2 - 1$$

$$U(3, x) = 8x^3 - 4x$$

$$U(4, x) = 16x^4 - 12x^2 + 1$$

$$U(5, x) = 32x^5 - 32x^3 + 6x$$

$$U(6, x) = 64x^6 - 80x^4 + 24x^2 - 1$$

$$U(7, x) = 128x^7 - 192x^5 + 80x^3 - 8x$$

$$U(8, x) = 256x^8 - 448x^6 + 240x^4 - 40x^2 + 1$$

$$U(9, x) = 512x^9 - 1024x^7 + 672x^5 - 160x^3 + 10x$$

See Also

The **chebyshev** function.

CheckBox

CheckBox [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The CheckBox operation creates or modifies a checkbox or radio button in the target window, which must be a graph or panel. *ctrlName* is the name of the checkbox.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the CheckBox control to be created or changed.

key is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of **default**, **native**, or **os9**.

platform can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

disable=*d*

Sets user editability of the control.

d=0: Normal.

d=1: Hide.

d=2: Disable user input.

fsize=*s*

Sets font size for checkbox.

help={*helpStr*}

Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.

mode=*m*

Specifies checkbox appearance.

m=0: Default checkbox appearance.

m=1: Display as a radio button control.

m=2: Display as a disclosure triangle (*Macintosh*) or treeview expansion node (*Windows*).

noproc

Specifies that no procedure is to execute when clicking the checkbox.

picture=*pict*

Draws the checkbox using the named picture. The picture is taken to be six side-by-side frames which show the control appearance in the normal state, when the mouse is down, and in the disabled state. The first three frames are used when the checked state is false and the next three show the true state. The picture may be either a global (imported) picture or a Proc Picture (see **Proc Pictures** on page IV-44).

pos={*left*,*top*}

Sets position of checkbox in pixels.

proc=*procName*

Specifies the procedure to execute when the checkbox is clicked.

rename=*newName*

Renames the checkbox to *newName*.

size={*width*,*height*}

Sets checkbox size in pixels.

title=*titleStr*

Sets title of checkbox to the specified string expression. The title is the text that appears in the checkbox. If not given or if " " then the title will be "New".

titleStr can contain formatting escape codes in order to create fancy, styled results.

The escape codes are the same as used by the **TextBox** operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired, click the To Cmd Line button, and then edit the TextBox command for use with the control.

userdata(*UDName*)=*UDStr*

Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*

Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

value=*v*

Specifies whether the checkbox is selected (*v*=1) or not (*v*=0).

CheckBox

`variable= varName` Specifies a global numeric variable to be set to the current state of a checkbox whenever it is clicked or when it is set by the value parameter. The variable is two-way: setting the variable also changes the state of the checkbox.

`win=winName` Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

`/Z` No error reporting.

Details

The target window must be a graph or panel.

The action procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName,checked) : CheckBoxControl
    String ctrlName
    Variable checked          // 1 if selected, 0 if not
    ...
End
```

The “: CheckBoxControl” puts the procedure in the Procedure pop-up menu in the CheckBox Control dialog.

The action procedure for a CheckBox control can also use a predefined structure `WMCheckboxAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a CheckBox control, otherwise it will use the old-style method.

A CheckBox action procedure using a structure has the format:

```
Function newActionProcName(CB_Struct)
    STRUCT WMCheckboxAction &CB_Struct
    ...
End
```

For a CheckBox control, the `WMCheckboxAction` structure has members as described in the following table:

WMCheckboxAction Structure Members

Member	Description						
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.						
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.						
<code>STRUCT Rect winRect</code>	Local coordinates of host window.						
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.						
<code>STRUCT Point mouseLoc</code>	Mouse location.						
<code>Int32 eventCode</code>	Event that executed the procedure.						
<table><tr><th>eventCode</th><th>Event</th></tr><tr><td>-1</td><td>Control being killed</td></tr><tr><td>2</td><td>Mouse up</td></tr></table>		eventCode	Event	-1	Control being killed	2	Mouse up
eventCode	Event						
-1	Control being killed						
2	Mouse up						
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of <code>MODIFIERS: flags</code> for SetWindow under Unnamed Hooks on page V-505.						
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.						
<code>Int32 checked</code>	Checkbox state.						

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

When using radio button controls, it is the responsibility of the Igor programmer to turn off other radio buttons when one of a group of radio buttons is pressed. The following code is an example of how to program such a group. (Copy the following code into the procedure window of a new experiment and then bring up the panel.)

```
Window Panel0() : Panel
    PauseUpdate; Silent 1          // building window ...
    NewPanel /W=(150,50,353,212)
    Variable/G gRadioVal= 1
    CheckBox check0,pos={52,25},size={78,15},title="Radio 1",value=1,mode=1,proc=MyCheckProc
    CheckBox check1,pos={52,45},size={78,15},title="Radio 2",value=0,mode=1,proc=MyCheckProc
    CheckBox check2,pos={52,65},size={78,15},title="Radio 3",value= 0,mode=1,proc=MyCheckProc
EndMacro

Function MyCheckProc(name,value)
    String name
    Variable value
    NVAR gRadioVal= root:gRadioVal
    strswitch (name)
        case "check0":
            gRadioVal= 1
            break
        case "check1":
            gRadioVal= 2
            break
        case "check2":
            gRadioVal= 3
            break
    endswitch
    CheckBox check0,value= gRadioVal==1
    CheckBox check1,value= gRadioVal==2
    CheckBox check2,value= gRadioVal==3
End
```

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

CheckBoxControl

CheckBoxControl

CheckBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined checkbox control. See **Procedure Subtypes** on page IV-149 for details.

CheckDisplayed

CheckDisplayed [/A/W] *waveName* [, *waveName*]...

The CheckDisplayed operation determines if named waves are displayed in a host window or subwindow.

Flags

/A	Checks all graph and table windows
/W= <i>winName</i>	Checks only the named graph or table window
	When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

If neither /A nor /W are used, CheckDisplayed checks only the top graph or table.

CheckDisplayed sets a bit in the variable V_flag for each wave that is displayed.

Examples

CheckDisplayed/W=Graph0 aWave,bWave,cWave

Checks Graph0 to see if aWave, bWave, and cWave are displayed in it. If aWave is displayed, CheckDisplayed sets bit 0 of V_flag (V_flag=1). If bWave is displayed, sets bit 1 (V_flag=2). If cWave is displayed, sets bit 2 (V_flag=4). If all three waves are displayed, V_flag=7.

See Also

Setting Bit Parameters on page IV-11 for information about bit settings.

CheckName

CheckName(*nameStr*, *objectType* [, *windowNameStr*])

The CheckName function returns a number which indicates if the specified name is legal and unique among objects in the namespace of the specified object type.

Waves, global numeric variables, and global string variables are all in the same namespace and need to be unique only within the data folder containing them. However, they also need to be distinct from names of Igor operations and functions and from names of user-defined procedures.

Data folders are in their own namespace and need to be unique only among other data folders at the same level of the data folder hierarchy.

windowNameStr is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

Details

A result of zero indicates that the name is legal and unique within its namespace. Any nonzero result indicates that the name is illegal or not unique. You can use the **CleanupName** and **UniqueName** functions to guarantee legality and uniqueness.

nameStr should contain an unquoted name (i.e., no single quotes for liberal names), such as you might receive from the user through a dialog or control panel.

objectType is one of the following:

- | | |
|--|---|
| 1: Wave. | 9: Control panel window. |
| 2: Reserved. | 10: Notebook window. |
| 3: Global numeric variable. | 11: Data folder. |
| 4: Global string variable. | 12: Symbolic path. |
| 5: XOP target window (e.g., surface plot). | 13: Picture. |
| 6: Graph window. | 14: Annotation in the named or topmost graph or layout. |
| 7: Table window. | 15: Control in the named topmost graph or panel. |
| 8: Layout window. | 16: Notebook action character in the named or topmost notebook. |

The *windowNameStr* argument is used only with *objectTypes* 14, 15, and 16. The *nameStr* is checked for uniqueness only within the named window (other windows might have objects with the given name). If a named window is given but does not exist, any valid *nameStr* is permitted

Examples

```
Variable waveNameIsOK = CheckName(proposedWaveName, 1) == 0
Variable annotationNameIsOK = CheckName("text0", 14, "Graph0")
```

See Also

CleanupName and **UniqueName** functions.

ChildWindowList

ChildWindowList(*hostNameStr*)

The ChildWindowList function returns a string containing a semicolon-separated list of immediate subwindow window names of the specified host window or subwindow.

Parameters

hostNameStr is a string or string expression containing the name of an existing host window or subwindow.

When identifying a subwindow with *hostNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Error if the host does not exist or if it is not an allowed host type.

See Also

WinList and **WinType** functions.

ChooseColor

ChooseColor [/C=(*r,g,b*)]

The ChooseColor operation displays a dialog for choosing a color.

The color initially shown is black unless you specify a different color with /C.

Flags

/C=(*r,g,b*) *r*, *g*, and *b* specify the amount of red, green, and blue in the color initially displayed in the dialog as an integer from 0 to 65535.

Details

ChooseColor sets the variable V_flag to 1 if the user clicks OK in the dialog or to 0 otherwise.

If V_flag is 1 then V_Red, V_Green, and V_Blue are set to the selected color as integers from 0 to 65535.

See Also

ImageTransform **rgb2hsl** and **hsl2rgb**.

CleanupName

CleanupName(*nameStr*, *beLiberal*)

The CleanupName function returns the input name string, possibly altered to make it a legal object name.

Details

nameStr should contain an unquoted (i.e., no single quotes for liberal names) name, such as you might receive from the user through a dialog or control panel.

beLiberal is 0 to use strict name rules or 1 to use liberal name rules. Strict rules allow only letters, digits and the underscore character. Liberal rules allow other characters such as spaces and dots. Liberal rules were introduced with Igor Pro 3.0 and are allowed for names of waves and data folders only.

Note that a cleaned up name is not necessarily unique. Call **CheckName** to check for uniqueness or **UniqueName** to ensure uniqueness.

Examples

```
String cleanStrVarName = CleanupName(proposedStrVarName, 0)
```

See Also

CheckName and **UniqueName** functions.

Close

Close [/A] *fileRefNum*

The Close operation closes a file previously opened by the **Open** operation or closes all such files if /A is used.

Parameters

fileRefNum is the file reference number of the file to close. This number comes from the Open operation. If /A is used, *fileRefNum* should be omitted.

Flags

/A Closes all files. Mainly useful for cleaning up after an error during procedure execution occurs so that the normal Close operation is never executed.

CloseMovie

CloseMovie

The CloseMovie operation closes the currently open movie. You must close a movie before you can play it.

See Also

The **NewMovie** operation.

CloseProc

CloseProc /NAME=*procNameStr* [*flags*]

CloseProc /FILE=*fileNameStr* [*flags*]

The CloseProc operation closes a procedure window. You cannot call CloseProc on the main Procedure window.

CloseProc provides a way to programmatically create and alter procedure files. You might do this in order to make a user-defined menu-bar menu with contents that change.

Note: CloseProc alters procedure windows so it cannot be called while functions or macros are running. If you want to call it from a function or macro, use **Execute/P**.

Warning: If you close a procedure window that has no source file or without specifying a destination file, the window contents will be permanently lost.

Flags

- /COMP[=*compile*] Specifies whether procedures should be compiled after closing the procedure window.
compile=1: Compiles procedures (same as /COMP only).
compile=0: Leaves procedures in an uncompiled state.
- /D[=*delete*] Specifies whether the procedure file should be deleted after closing the procedure window.
delete=1: Deletes procedure file (same as /D only). **Warning:** You cannot recover any file deleted this way.
delete=0: Leaves any associated file unaffected.
- /FILE=*fileNameStr* Identifies the procedure window to close using the file name and path to the file given by *fileNameStr*. The string can be just the file name if /P is used to specify a symbolic path name of the enclosing folder. It can be a partial path if /P points to a folder enclosing the start of the partial path. It can also be a full path the file.
- /NAME=*procNameStr* Identifies the procedure window to close with the string expression *procNameStr*. This is the same text that appears in the window title. If the procedure window is associated with a file, it will be the file name and extension.
- /P=*pathname* Specifies the folder to look in for the file specified by /FILE. *pathname* is the name of an existing symbolic path.
- /SAVE[=*savePathStr*] Saves the procedure before closing the window. If the flag is used with no argument, it saves any changes to the procedure window to its source file before closing it. If *savePathStr* is present, it must be a full path naming a file in which to save the procedure window contents. The /P flag is not used with *savePathStr* so it must be a full path.

Details

Specify which window to close using either the /NAME or /FILE flag. You must use one or the other. Usually you would use /NAME, as it is usually more convenient. If by some chance two procedures have the same name, /FILE can be used to distinguish between them.

You cannot call CloseProc on a nonmain procedure window that someone has had the bad taste to call "Procedure".

See Also

Chapter III-13, **Procedure Windows**.

The **Execute/P** operation.

cmplx

cmplx(*realPart*, *imagPart*)

The cmplx function returns a complex number whose real component is *realPart* and whose imaginary component is *imagPart*.

Use this to assign a value to a complex variable or complex wave.

Examples

Assume wave1 is complex. Then:

```
wave1(0) = cmplx(1,2)
```

sets the Y value of wave1 at x=0 such that its real component is 1 and its imaginary component is 2.

Assuming wave2 and wave3 are real, then:

```
wave1 = cmplx(wave2,wave3)
```

sets the real component of wave1 equal to the contents of wave2 and the imaginary component of wave1 equal to the contents of wave3.

You may get unexpected results if the number of points in wave2 or wave3 differs from the number of points in wave1. If wave2 or wave3 are shorter than wave1, the last element of the short wave is copied repeatedly to fill wave1.

See Also

conj, **imag**, **magsqr**, **p2rect**, **r2polar**, and **real** functions.

cmpstr

```
cmpstr(str1, str2 [, flags])
```

The cmpstr function returns -1, 0 or 1 depending on how string *str1* compares alphabetically to string *str2*.

Details

cmpstr returns the following values:

- 1: *str1* is alphabetically before *str2*.
- 0: *str1* and *str2* are equal.
- 1: *str1* is alphabetically after *str2*.

If *flags* is not present, or if *flags* is zero, case (upper or lower) is not significant. Set *flags* to 1 for a case-sensitive comparison.

See Also

The **ReplaceString** function.

ColorScale

```
ColorScale [flags] [, keyword = value, ...] [axisLabelStr]
```

The ColorScale operation puts a color scale (or “color legend”) annotation on the top graph or page layout.

The ColorScale operation can be executed with no flags and no parameters.

When a graph is the top window the color scale represents the colors and values associated with the first image plot that was added to the graph.

If there is no image plot in the graph, the color scale represents the first contour plot or first $f(z)$ trace added to the graph, one of which must exist for the command to execute without error when executed without parameters.

Executing ColorScale (with no parameters) when a layout is the top window displays a color bar as if the `ctab={0,100,Rainbow}` parameters had been specified.

Flags

Use the `/W=winName` flag to specify a specific graph or layout window. When used on the command line or in a Macro or Proc, `/W` must precede all other flags.

To change a color scale, use the `/C/N=name` flags. Annotations are automatically named “text0”, “text1”, etc. if no name is specified when it is created, and you must use that name to modify an existing annotation or else a new one will be created.

For explanations of all flags see the **TextBox** operation.

Parameters

The following keyword-value pairs are the important parameters to the ColorScale operation, because they specify what object the color scale is representing.

Note: For use with page layouts, the keyword `= {graphName,...}` form is required.

For graphs it is simpler to use the `image=imageInstanceName` form (omitting graphName), though you can use `$ " "` to mean the top graph, or specify the name of another graph with the long form. See the **Examples**.

ColorScale

<i>axisLabelStr</i>	Contains the text printed beside the color scale's main axis. This text is interpreted the same way as for the Label operation. It may contain escape codes to alter the text color or display subscripts, for example. You can use AppendText or ReplaceText to modify this axis label string. The default value for <i>axisLabelStr</i> is "".
<i>cindex=cindexMatrixWave</i>	<p>The colors shown are those in the named color index wave with axis values derived from the wave's X (row) scaling and units.</p> <p>The image colors are determined by doing a lookup in the specified matrix wave. See the ModifyImage cindex keyword.</p>
<i>contour=contourInstanceName</i> <i>contour={graphName,contourInstanceName}</i>	<p>The colors show the named contour plot's colors and associated contour (Z) values and contour data units. All of the image plot's characteristics are represented, including color table, <i>cindex</i>, and fixed colors.</p>
<i>ctab={zMin,zMax,ctName, mode}</i>	<p>The color table specified by <i>ctName</i> is drawn in the color legend. <i>ctName</i> can be any of those returned by the CTabList function, such as Grays or Rainbow. Also see Color Tables on page II-327.</p> <p>The color table name can be omitted if you want to leave it unchanged. <i>zMin</i> and <i>zMax</i> set the range of Z values to map. Set parameter <i>mode</i> to 1 to reverse the color table; zero or missing value does not reverse the color table.</p>
<i>image=imageInstanceName</i> <i>image={graphName,imageInstanceName}</i>	<p>The colors show the named image plot's colors and associated image (Z) values and image data units. All of the image plot's characteristics are represented, including color table, <i>cindex</i>, lookup wave, eval colors, and NaN transparency. Note: only false-color image plots can be used with ColorScale (see Indexed Color Details on page II-333).</p>
<i>lookup= waveName</i>	<p>Specifies an optional 1D wave used to modify the mapping of scaled Z values into the color table specified with the <i>ctab</i> keyword. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use <i>lookup=\$</i> " " to remove option.</p> <p>This keyword is not needed with the <i>image</i> keyword, even if the image plot uses a lookup wave. The image plot's lookup wave is used instead of the ColorScale lookup wave.</p>
<i>trace=traceInstanceName</i> <i>trace={graphName,traceInstanceName}</i>	<p>The colors show the color(s) of the named trace. This is useful when the trace has its color set by a "Z wave" using the ModifyGraph zColor(traceName)=... feature. In the Modify Trace Appearance dialog this is selected in the "Set as f(z)" subdialog. The color scale's main axis shows the range of values in the Z wave, and displays any data units the wave may have.</p>

Size Parameters

The following keyword-value parameters modify the size of the color scale annotation. These keywords are similar to those used by the **Slider** control. The size of the annotation is indirectly controlled by setting the size of the "color bar" and the various axis parameters. The annotation sizes itself to accommodate the color bar, tick labels, and axis label(s).

<i>height=h</i>	Sets the height of the color bar in points, overriding any <i>heightPct</i> setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default is restored by specifying <i>height=0</i> . Specifying a <i>heightPct</i> value resets height to this default.
<i>heightPct=hpct</i>	Sets height as a percentage of the graph's plot area, overriding any height setting. The default height is 75% of the plot area height if the color scale is vertical, or a constant of 15 points if the color scale is horizontal. The default height is restored by setting <i>heightPct=0</i> . Specifying a height value resets <i>heightPct</i> to this default.
<i>side=s</i>	<p>Selects on which axis to draw main axis ticks.</p> <p><i>s=1:</i> Right of the color bar if <i>vert=1</i>, or below if <i>vert=0</i>.</p>

	<i>s</i> =2: Left of the color bar if <i>vert</i> =1, or above if <i>vert</i> =0.
<i>vert</i> = <i>v</i>	Specifies color scale orientation. <i>v</i> =0: Horizontal. <i>v</i> =1: Vertical (default).
<i>width</i> = <i>w</i>	Sets the width of the color bar in points, overriding any <i>widthPct</i> setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by specifying <i>width</i> =0. Specifying a <i>widthPct</i> value resets <i>width</i> to this default.
<i>widthPct</i> = <i>wpct</i>	Sets <i>width</i> as a percentage of the graph's plot area, overriding any <i>width</i> setting. The default width is a constant 15 points if the color scale is vertical, or 75% of the plot area width if the color scale is horizontal. The default is restored by setting <i>widthPct</i> =0. Specifying a <i>width</i> value resets <i>widthPct</i> to this default.

Color Bar Parameters

The following keyword-value parameters modify the appearance of the color scale color bar.

<i>colorBoxesFrame</i> = <i>on</i>	Draws frames surrounding up to 99 swatches of colors in the color bar (<i>on</i> =1). When specifying more than 99 colors in the color bar (such as the Rainbow color table, which has 100 colors), the boxes aren't framed. Framing color boxes is effective only for small numbers of colors. Set the width of the frame with the <i>frame</i> keyword. Use <i>on</i> =0 to turn off color box frames.
<i>frame</i> = <i>f</i>	Specifies the thickness of the frame drawn around the color bar in points (<i>f</i> can range from 0 to 5 points). The default is 1 point. Fractional values are permitted. Turn frames off with <i>f</i> =0. Values less than 0.5 do not display on screen, but the thin frame will print.
<i>frameRGB</i> =(<i>r</i> , <i>g</i> , <i>b</i>) or 0	Sets the color of the frame around the color bar. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue as an integer from 0 to 65535. The frame includes the individual color bar colors when <i>colorBoxesFrame</i> =1. The frame will use the colorscale foreground color, as set by the /G flag, when <i>frameRGB</i> =0.

Axis Parameters

The following keyword-value parameters modify the appearance of the color scale axes. These keywords are based on the **ModifyGraph** Axis keywords because they modify the main or secondary color scale axes.

<i>axisRange</i> ={ <i>zMin</i> , <i>zMax</i> }	Sets the color bar axis range to values specified by <i>zMin</i> and <i>zMax</i> . Use * to use the default axis range for either or both values. Omit <i>zMin</i> or <i>zMax</i> to leave that end of the range unchanged. For example, use { <i>zMin</i> , } to change <i>zMin</i> and leave <i>zMax</i> alone, or use { , * } to set only the axis maximum value to the default value.
<i>dateInfo</i> ={ <i>sd</i> , <i>tm</i> , <i>dt</i> }	Controls formatting of date/time axes. <i>sd</i> =0: Show date in the date&time format. <i>sd</i> =1: Suppress date. <i>tm</i> =0: 12 hour (AM/PM) time. <i>tm</i> =1: 24 hour (military) time. <i>tm</i> =2: Elapsed time. <i>dt</i> =0: Short dates (2/22/90). <i>dt</i> =1: Long dates (Thursday, February 22, 1990). <i>dt</i> =2: Abbreviated dates (Thurs, Feb 22, 1990). These have no effect unless the axis is controlled by a wave with 'dat' data units. For an f(z) color scale: SetScale d, 0,0, "dat", fOfZWave

	For a contour plot or image plot color scale: SetScale d, 0,0, "dat", ZorXYZorImageWave See Date/Time Axes on page II-255 and Date, Time, and Date&Time Units on page II-72 for details on how date/time axes work.
font=fontNameStr	Name of font as string expression. If the font does not exist, the default font is used. Specifying "default" has the same effect. Unlike ModifyGraph, the fontNameStr is evaluated at runtime, and its absence from the system is not an error.
fs=s	Sets the font size in points. s=0: Use the graph font size for tick labels and axis labels (default).
fstyle=fs	Sets the font style. fs is a binary coded number with each bit controlling one aspect of the font style for the tick mark labels: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (Macintosh only). bit 4: Shadow (Macintosh only). bit 5: Condensed (Macintosh only). bit 6: Extended (Macintosh only). See Setting Bit Parameters on page IV-11 for details about bit settings.
highTrip=h	If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation. The default highTrip is 100,000.
lblLatPos=p	Sets a lateral offset for the main axis label. This is an offset parallel to the axis. p is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.
lblMargin=m	Moves the main axis label by m points (default is 0) from the normal position. The default value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.
lblRot=r	Rotates the main axis label by r degrees counterclockwise starting from the normal label orientation. Valid rotations are 0 (default), 90, 180, and 270.
log=l	Specifies the axis type. l=0: Linear (default). l=1: Log base 10. l=2: Log base 2.
logHTrip=h	Same as highTrip but for log axes. The default is 10,000.
logLTrip=l	Same as lowTrip but for log axes. The default is 0.0001.
logTicks=t	Specifies the maximum number of decades in log axis before minor ticks are suppressed.
lowTrip=l	If the axis extrema are between its lowTrip and its highTrip, then tick mark labels use fixed point notation. Otherwise, they use exponential (scientific or engineering) notation. The default lowTrip is 0.1.
minor=m	m=0: Disables minor ticks (default). m=1: Enables minor ticks.
notation=n	n=0: Engineering notation (default). n=1: Scientific notation.
nticks=n	Specifies the approximate number of ticks to be distributed along the main axis. Ticks are labelled using the same automatic algorithm used for graph axes. The default is 5. n=0: No ticks.
prescaleExp=exp	Multiplies axis range by 10exp for tick labeling and exp is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. The default is 0 (no modification). See the discussion in the ModifyGraph (axes) Details section.
tickExp=te	te=1: Forces tick labels to exponential notation when labels have units with a prefix.

	<i>te</i> =0: Turns off exponential notation.
<i>tickLen</i> = <i>t</i>	Sets the length of the ticks. <i>t</i> is the major tick mark length in points. This value must be between -100 and 50.
	<i>t</i> =0 to 50: Draws tick marks between the tick labels and the colors box.
	<i>t</i> =-1: Default; auto tick length, equal to 70% of the tick label font size. Draws tick marks between the tick labels and the colors box.
	<i>t</i> =-2 to -50: Draws tick marks crossing the edge of the colors box nearest the tick labels. The actual total tick mark length is - <i>t</i> .
	<i>t</i> =-100 to -51: Draws tick marks inside the edge of the colors box nearest the tick labels. Actual tick mark length is -(<i>t</i> +50). For example, -58 makes in an inside tick mark that is 8 points long.
<i>tickThick</i> = <i>t</i>	Sets the tick mark thickness in points (from 0 to 5 points). The default is 1 point. Fractional values are permitted.
	<i>t</i> =0: Turns tick marks off, but not the tick labels.
<i>tickUnit</i> = <i>tu</i>	Turns on (<i>tu</i> =0) or off (<i>tu</i> =1) units labels attached to tick marks.
<i>userTicks</i> = <i>{tvWave,tblWave}</i>	Supplies user defined tick positions and labels for the main axis. <i>tvWave</i> contains the numeric tick positions while text wave <i>tblWave</i> contains the corresponding labels. The tick mark labels can be multiline and use styled text. For more details, see Fancy Tick Mark Labels on page II-290. Overrides normal ticking specified by <i>nticks</i> .
<i>ZisZ</i> = <i>z</i>	<i>z</i> =1 labels the zero tick mark (if any) with the single digit "0" regardless of the number of digits used for other labels. Default is <i>z</i> =0.

Secondary Axis Parameters

<i>axisLabel2</i> = <i>axisLabelString2</i>	Axis label for the secondary axis. This axis label is drawn only if <i>userTicks2</i> is in effect. Text after any \r character is ignored, as is the \r character. The default is "".
<i>lblLatPos2</i> = <i>p</i>	Sets lateral offset for secondary axis labels. This is an offset parallel to the axis. <i>p</i> is in points. Positive is down for vertical axes and to the right for horizontal axes. The default is 0.
<i>lblMargin2</i> = <i>m</i>	Specifies the distance in points (default 0) to move the secondary axis label from the position that would be normal for a graph. The default is value is -5, which brings the axis label closer to the axis. Use more positive values to move the axis label away from the axis.
<i>lblRot2</i> = <i>r</i>	Rotates the secondary axis label by <i>r</i> degrees counterclockwise starting from the normal label orientation. Valid rotations are 0 (default), 90, 180, and 270.
<i>userTicks2</i> = <i>{tvWave,tblWave}</i>	Supplies user defined tick positions and labels for a second axis which is always on the opposite side of the color bar from the main axis. The tick mark labels can be multiline and use styled text. For more details, see Fancy Tick Mark Labels on page II-290. This is the only way to draw a second axis.

Examples

```
Make/O/N=(20,20) img=p*q; NewImage img           // Make and display an image
ColorScale                                       // create default color scale
// first annotation is text0
ColorScale/C/N=text0 nticks=3,minor=1,"Altitude"
```

```
ModifyImage img ctab= {*,*,Relief19,0}           // 19-color color table
ColorScale/C/N=text0 axisRange={100,300}         // Detail for 100-300 range
```

ColorTab2Wave

```
ColorScale/C/N=text0 colorBoxesFrame=1           // Frame the color boxes
ColorScale/C/N=text0 frameRGB=(65535,0,0)        // Red frame
```

See Also

For all other flags see the **TextBox** and **AppendText** operations.

ColorTab2Wave

ColorTab2Wave *colorTableName*

The ColorTab2Wave operation extracts colors from the built-in color table and places them in an Nx3 matrix of red, green, and blue columns named M_colors. Values are unsigned 16-bit integers and range from 0 to 65535.

N will typically be 100 but may be as little as 9 and as large as 476. Use

```
Variable N= DimSize(M_colors,0)
```

to determine the actual number of colors.

The wave M_colors is created in the current data folder. Red is in column 0, green is in column 1, and blue in column 2.

Parameters

colorTableName can be any of those returned by **CTabList**, such as Grays or Rainbow.

Details

See **Color Tables** on page II-327.

Concatenate

Concatenate [*type flags*][*flags*] *waveListStr*, *destWave*

Concatenate [*type flags*][*flags*] {*wave1*, *wave2*, *wave3*,...}, *destWave*

The Concatenate operation combines data from the source wave(s) into *destWave*, which will be created if it does not already exist, or if it exists and is not overwritten, will have the source wave(s) concatenated with it.

Parameters

waveListStr is a string expression containing a list of wave names separated by semicolons. The list must be terminated with a semicolon. The alternate syntax using {*wave1*, *wave2*, ...} is limited to 100 waves or less, but there is no limit when using *waveListStr*.

destWave is the name of a new or existing wave that will contain the concatenation result.

Flags

/DL Sets dimension labels. For promotion, it uses source wave names as new dimension labels otherwise it uses existing labels.

/KILL Kills source waves.

/NP Prevents promotion to higher dimension.

/O Overwrites *destWave*.

Type Flags (*used only in functions*)

Concatenate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Details

If *destWave* does not already exist or, if the /O flag is used, *destWave* is created by duplication of the first source wave. Waves are concatenated in order through the list of source waves. If *destWave* exists and the /O flag is not used, then the concatenation starts with *destWave*.

destWave cannot be used in the source wave list.

Source waves must be either all numeric or all text.

The number of low-order dimensions that all waves share in common determines the dimensionality of *destWave* so that the dimensionality of *destWave* will then be one greater. The default behaviors will vary according to the source wave sizes. Concatenating 1D waves that are all the same length will produce a matrix, whereas concatenating 1D waves of differing lengths will produce a 1D wave. Similarly, concatenating 2D waves of the same size will produce a volume; but if the 2D source waves have differing numbers of columns then *destWave* will be a 2D wave, or if the 2D waves have differing numbers of rows then *destWave* will be a 1D wave. Concatenating 1D and 2D waves that have the same number of rows will produce a 2D wave, but when the number of rows differs, *destWave* will be a 1D wave. See the Examples.

Use the /NP flag to suppress dimension promotion and keep the dimensionality of *destWave* the same as the input waves.

Examples

Given the following waves:

```
Make/N=10 w1,w2,w3
Make/N=11 w4
Make/N=(10,7) m1,m2,m3
Make/N=(10,8) m4
Make/N=(9,8) m5
```

Concatenating 1D waves:

```
Concatenate/O {w1,w2,w3},wdest // wdest is a 10x3 matrix
Concatenate {w1,w2,w3},wdest // wdest is a 10x6 matrix
Concatenate/NP/O {w1,w2,w3},wdest // wdest is a 30-point 1D wave
Concatenate/O {w1,w2,w3,w4},wdest // wdest is a 41-point 1D wave
```

Concatenating 2D waves:

```
Concatenate/O {m1,m2,m3},wdest // wdest is a 10x7x3 volume
Concatenate/NP/O {m1,m2,m3},wdest // wdest is a 10x21 matrix
Concatenate/O {m1,m2,m3,m4},wdest // wdest is a 10x29 matrix
Concatenate/O {m4,m5},wdest // wdest is a 152-point 1D wave
```

Concatenating 1D and 2D waves:

```
Concatenate/O {w1,m1},wdest // wdest is a 10x8 matrix
Concatenate/O {w4,m1},wdest // wdest is a 81-point 1D wave
```

See Also

The **Duplicate** and **Redimension** operations.

conj

conj(z)

The conj function returns the complex conjugate of the complex value z.

See Also

cmplx, imag, magsqr, p2rect, r2polar, and real functions.

Constant

Constant kName = literalNumber

The Constant declaration defines the number *literalNumber* under the name *kName* for use by other code, such as in a switch construct.

See Also

The **Strconstant** keyword for string types, **Constants** on page IV-38 and **Switch Statements** on page IV-33.

continue

continue

The continue flow control keyword returns execution to the beginning of a loop, bypassing the remainder of the loop's code.

See Also

Continue Statement on page IV-36 and **Loops** on page IV-34 for usage details.

ContourInfo

ContourInfo(graphNameStr, contourWaveNameStr, instanceNumber)

The ContourInfo function returns a string containing a semicolon-separated list of information about the specified contour plot in the named graph.

Parameters

graphNameStr can be "" to refer to the top graph.

contourWaveNameStr is a string containing either the name of a wave displayed as a contour plot in the named graph, or a contour instance name (wave name with “#n” appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instanceNumber* to 1 for information about the second contour plot of the wave, etc. If *contourWaveNameStr* is "", then information is returned on the *instanceNumber*th contour plot in the graph.

If *contourWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *contourWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *contourWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
DATAFORMAT	Either XYZ or Matrix.
LEVELS	A comma-separated list of the contour levels, including the final automatic levels, (or manual or from-wave levels), and the “more levels”, all sorted into ascending Z order.
RECREATION	List of keyword commands as used by ModifyContour command. The format of these keyword commands is: <i>keyword (x)=modifyParameters;</i>
TRACESFORMAT	The format string used to name the contour traces (see AppendMatrixContour or AppendXYZContour).
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	Full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.

Keyword	Information Following Keyword
YWAVEDF	Full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data from which the contour plot was calculated.
ZWAVEDF	Full path to the data folder containing the Z data wave.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyContour”, replace the “x” with the name of a contour plot (“data#1” for instance) and then **Execute** the resultant string as a command.

Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack           // Second instance of jack
```

This example accesses the contour information for the second contour plot of the wave “jack” (which has an instance number of 1) displayed in the top graph:

```
Print StringByKey("ZWAVE", ContourInfo("", "jack", 1))           // prints jack
```

See Also

The **Execute** and **ModifyContour** operations.

ContourNameList

ContourNameList(*graphNameStr*, *separatorStr*)

The ContourNameList function returns a string containing a list of contours in the graph window or subwindow identified by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single character such as “,” or “;” to separate the names.

A contour name is defined as the name of the wave containing the data from which a contour plot is calculated, with an optional #n suffix that distinguishes between two or more contour plots in the same graph window that have the same wave name. Since the contour name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely contour display. If you did this, you would most likely want to put each contour plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack, 'jack # 2';
Display;AppendMatrixContour jack
AppendMatrixContour/T/R jack
AppendMatrixContour 'jack # 2'
AppendMatrixContour/T/R 'jack # 2'
Print ContourNameList("", ";")
prints jack; jack#1; 'jack # 2'; 'jack # 2' #1;
```

See Also

Another command related to contour plots and waves: **ContourNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ImageNameList**, and **ImageNameToWaveRef**.

ContourNameToWaveRef

ContourNameToWaveRef(*graphNameStr*, *contourNameStr*)

Returns a wave reference to the wave corresponding to the given contour name in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The contour name is identified by the string in *contourNameStr*, which could be a string determined using ContourNameList. Note that the same contour name can refer to different waves in different graphs, if the waves are in different data folders.

See Also

The **ContourNameList** function.

For a discussion of wave reference functions, see **Wave Reference Functions** on page IV-143.

ContourZ

ContourZ(*graphNameStr*, *contourInstanceNameStr*, *x*, *y*)

The ContourZ function returns the interpolated Z value of the named contour plot data displayed in the named graph.

For gridded contour data, ContourZ returns the bilinear interpolation of the four surrounding XYZ values.

For XYZ triplet contour data, ContourZ returns the value interpolated from the three surrounding XYZ values identified by the Delaunay triangulation.

Parameters

graphNameStr can be "" to specify the topmost graph.

contourNameStr is a string containing either the name of the wave displayed as a contour plot in the named graph, or a contour instance name (wave name with “#n” appended to distinguish the nth contour plot of the wave in the graph). You might get a contour instance name from the **ContourNameList** function.

If *contourNameStr* contains a wave name, *instance* identifies which contour plot of *contourNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a wave displayed as a contour plot in a graph. Set *instance* to 1 for information about the second contour plot of *contourNameStr*, etc. If *contourNameStr* is "", then information is returned on the *instanceth* contour plot in the graph.

If *contourNameStr* contains an instance name, and *instance* is zero, the instance is taken from *contourNameStr*. If *instance* is greater than zero, the wave name is extracted from *contourNameStr*, and information is returned concerning the *instanceth* instance of the wave.

x and *y* specify the X and Y coordinates of the value to be returned. This may or may not be the location of a data point in the wave selected by *contourNameStr* and *instance*.

Details

For gridded contour data, ContourZ returns NaN if *x* or *y* falls outside the XY domain of the contour data. If *x* and *y* fall on the contour data grid, the corresponding Z value is returned.

For XYZ triplet contour data, ContourZ returns the null value if *x* or *y* falls outside the XY domain of the contour data. You can set the null value to *v* with this command:

```
ModifyContour contourName nullValue=v
```

If *x* and *y* match one of the XYZ triplets, the corresponding Z value from the triplet is returned.

Examples

Because ContourZ can interpolate the Z value of the contour data at any X and Y coordinates, you can use ContourZ to convert XYZ triplet data into gridded data:

```
// Make example XYZ triplet contour data
Make/O/N=50 wx,wy,wz
wx= enoise(2)           // x = -2 to 2
wy= enoise(2)           // y = -2 to 2
wz= exp(-(wx[p]*wx[p] + wy[p]*wy[p])) // XY gaussian, z= 0 to 1
```

```
// ContourZ requires a displayed contour data set
Display; AppendXYZContour wz vs {wx,wy};DelayUpdate
ModifyContour wz autolevels={*,*,0} // no contour levels are needed
ModifyContour wz xymarkers=1 // show the X and Y locations

// Convert to grid: Make matrix that spans X and Y
Make/O/N=(30,30) matrix
SetScale/I x, -2, 2, "", matrix
SetScale/I y, -2, 2, "", matrix
matrix= ContourZ("", "wz", 0,x,y) // or = ContourZ("", "", 0,x,y)
AppendImage matrix
```

See Also

The **AppendMatrixContour**, **AppendXYZContour**, and **ModifyContour** operations. The **zcsr** and **ContourInfo** functions.

ControlBar

ControlBar [*flags*] *barHeight*

The ControlBar operation sets the height and location of the control bar in a graph.

Parameters

barHeight is in pixels. Setting *barHeight* to zero removes the control bar.

Flags

/L/R/B/T Designates whether to use the Left, Right, Bottom, or Top (default) window edge, respectively, for the control bar location.

/W=*graphName* Specifies the name of a particular graph containing a control bar.

Details

The control bar is an area at the top of graphs reserved for controls such as buttons, checkboxes and pop-up menus. A line is drawn between this area and the graph area. The control bar may be assigned a separate background color by pressing Control (*Macintosh*) or Ctrl (*Windows*) and clicking in the area, by right-clicking it (*Windows*), or with the **ModifyGraph** operation. You can not use draw tools in this area.

For graphs with no controls you do not need to use this operation.

Examples

```
Display myData
ControlBar 35 // 35 pixels high
Button button0,pos={56,8},size={90,20},title="My Button"
```

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

ControlInfo

ControlInfo [/W=*winName*] *controlName*

The ControlInfo operation returns information about the state or status of the named control in a graph or control panel window or subwindow.

Flags

/W=*winName* Looks for the control in the named graph or panel window or subwindow. If /W is omitted, ControlInfo looks in the top graph or panel window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Parameters

controlName is the name of the control in *winName* or in the top graph or panel window. *controlName* may also be the keyword **kwBackgroundColor** to set V_Red, V_Green, and V_Blue, the keyword **kwControlBar** to set V_Height, or the keyword **kwSelectedControl** to set S_value and V_flag.

Details

Information for all controls is returned via the following string and numeric variables:

S_recreation Commands to recreate the named control.

V_disable Disable state of control:

- 0: Normal (enabled, visible).
- 1: Hidden.
- 2: Disabled, visible.

V_Height, V_Width, V_top, V_left

Dimensions and position of the named control in pixels.

The kind of control is returned in V_flag as a positive or negative integer. A negative value indicates the control is incomplete or not active. If V_flag is zero, then the named control does not exist. Information returned for specific control types is as follows:

Button	V_flag	1
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
Chart	V_flag	6 or -6
	V_value	Current point number.
	S_value	Keyword-packed information string. See S_value for Chart Details for more keyword information.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
CheckBox	V_flag	2
	V_value	0 if it is deselected or 1 if it is selected.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
CustomControl	V_flag	12
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_value	Name of the picture used to define the control appearance.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
GroupBox	V_flag	9
	S_value	Title text.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
ListBox	V_flag	11
	V_value	Currently selected row (valid for mode 1 or 2 or modes 5 and 6 when no selWave is used). If no list row is selected, then it is set to -1.
	V_selCol	Currently selected column (valid for modes 5 and 6 when no selWave is used).
	V_horizScroll	Number of pixels the list has been scrolled horizontally to the right.
	V_vertScroll	Number of pixels the list has been scrolled vertically downwards.
	V_rowHeight	Height of a row in pixels.
	V_startRow	The current top visible row.
	S_columnWidths	A comma-separated list of column widths in pixels.
	S_dataFolder	Full path to listWave (if any).
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.

	S_value	Name of listWave (if any).
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
PopupMenu	V_flag	3 or -3
	V_Red, V_Green, V_Blue	For color array pop-up menus, these are the encoded color values.
	V_value	Current item number (counting from one).
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_value	Text of the current item. If PopupMenu is a color array then it contains color values encoded as (r,g,b) where r , g , and b are integers from 0 to 65535.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
SetVariable	V_flag	5 or -5
	V_value	Value of the variable. If the SetVariable is used with a string variable, then it is the interpretation of the string as a number, which will be NaN if conversion fails.
	S_dataFolder	Full path to the variable.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_value	Name of the variable.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
Slider	V_flag	7
	V_value	Numeric value of the variable.
	S_dataFolder	Full path to the variable.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_value	Name of the variable.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
TabControl	V_flag	8
	V_value	Number of the current tab.
	S_UserData	Primary (unnamed) user data text. For retrieving any named user data, you must use the GetUserData operation.
	S_value	Tab text.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
TitleBox	V_flag	10
	S_dataFolder	Full path if text is from a string variable.
	S_value	Name if text is from a string variable.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.
ValDisplay	V_flag	4 or -4
	V_value	Displayed value.
	S_value	Text of expression that ValDisplay evaluates.
	S_recreation, V_disable, V_Height, V_Width, V_top, V_left	See descriptions of these at the beginning of this section.

ControlNameList

kwBackgroundColor

V_Red, V_Green, V_Blue

If *controlName* is kwBackgroundColor then this is the color of the control panel background. This color is usually the default user interface background color, as set by the Appearance control panel on the Macintosh or by the Appearance tab of the Display Properties on Windows, until changed by ModifyPanel cbRGB.

kwControlBar

V_Height

If *controlName* is kwControlBar then this is the height (in pixels) of the control bar area in a graph or of an entire panel.

kwSelectedControl

V_flag

If *controlName* is kwSelectedControl then V_flag is 1 if a control is selected or 0 if not. (**SetVariable** and **ListBox** controls can be selected, most other controls cannot.)

S_value

Name of selected control (if any) or " ".

S_value for Chart Details

The following applies *only* to the keyword-packed information string returned in S_value for a chart. S_value will consist of a sequence of sections with the format: "*keyword:value*;" You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the S_value keywords:

Keyword	Type	Meaning
FNAME	string	Name of the FIFO chart is monitoring.
LHSAMP	number	Left hand sample number.
NCHANS	number	Number of channels displayed in chart.
PPSTRIP	number	The chart's points per strip value.
RHSAMP	number	Right hand sample number (same as V_value).

In addition, ControlInfo writes fields to S_value for each channel in the chart. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the S_value string: "CHNAME4:Pressure". In the following table, the channel's number is represented by #:

Keyword	Type	Meaning
CHCTAB#	number	Channel's color table value as set by Chart ctab keyword.
CHGAIN#	number	Channel's gain value as set by Chart gain keyword.
CHNAME#	string	Name of channel defined by FIFO.
CHOFFSET#	number	Channel's offset value as set by Chart offset keyword.

Examples

```
ControlInfo myChart; Print S_value
```

Prints the following to the history area:

```
FNAME:myFIFO;NCHANS:1;PPSTRIP:1100;RHSAMP:271;LHSAMP:-126229;
```

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

ControlNameList

ControlNameList(winNameStr [, listSepStr [, matchStr]])

The ControlNameList function returns a string containing a list of control names in the graph or panel window or subwindow identified by *winNameStr*.

Parameters

winNameStr can be "" to refer to the top graph or panel window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The optional parameter *listSepStr* should contain a single character such as "," or ";" to separate the names; the default value is ";".

The optional parameter *matchStr* is some combination of normal characters and the asterisk wildcard character that matches anything. To use *matchStr*, *listSepStr* must also be used. See **stringmatch** for wildcard details.

Only control names that satisfy the match expression are returned. For example, "*" _tab0" matches all control names that end with "_tab0". The default is "*", which matches all control names.

Examples

```
NewPanel
Button myButton
Checkbox myCheck
Print ControlNameList("")           // prints "myButton;myCheck;"
Print ControlNameList("", ";", "*Check") // prints "myCheck;"
```

See Also

ControlUpdate

ControlUpdate [/A/W=*winName*] [*controlName*]

The ControlUpdate operation updates the named control or all controls in a window, which can be the top graph or control panel or the named graph or control panel if you use /W.

Flags

/A	Updates all controls in the window. You must omit <i>controlName</i> .
/W= <i>winName</i>	Specifies the window or subwindow containing the control. If you omit <i>winName</i> it will use the top graph or control panel window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

ControlUpdate is useful for forcing a pop-up menu to rebuild, to update a ValDisplay control, or to forcibly accept a SetVariable's currently-being-edited value.

Normally, a pop-up menu rebuilds only when the user clicks on it. If you set up a pop-up menu so that its contents depend on a global string variable, on a user-defined string function or on an Igor function (e.g., **WaveList**), you may want to force the pop-up menu to be updated at your command.

Usually, a ValDisplay control displays the value of a global variable or of an expression involving a global variable. If the global variable changes, the ValDisplay will automatically update. However, you can create a ValDisplay that displays a value that does not depend on a global variable. For example, it might display the result of an external function. In a case like this, the ValDisplay will not automatically update. You can update it by calling ControlUpdate.

When a SetVariable control is being edited, the text the user types isn't "accepted" (or processed) until the user presses Return or Enter. ControlUpdate effectively causes the named control to act as though the user has pressed one of those keys. If /A is specified, the currently active SetVariable control (if any) is affected this way. The motivation here is that the user may have typed a new value without having yet pressed return, and then may click a button in a different panel which runs a routine that uses the SetVariable value as input. The user expected the typed value to have been accepted but the variable has not yet been set. Calling ControlUpdate /A on the first panel will read the typed value in the variable, avoiding a discrepancy between the visible value of the SetVariable control and the actual value of the variable.

Examples

```
NewPanel;DoWindow/C PanelX
String/G popupList="First;Second;Third"
PopupMenu oneOfThree value=popupList           // popup shows "First"
```

ConvexHull

```
popupList="1;2;3" // popup is unchanged
ControlUpdate/W=PanelX oneOfThree // popup shows "1"
```

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **ValDisplay** and **WaveList** operations.

ConvexHull

convexHull [*flags*] *xwave*, *ywave*

convexHull [*flags*] *tripletWave*

The ConvexHull operation calculates the convex hull in either 2 or 3 dimensions. The dimensionality is deduced from the input wave(s). If the input consists of two 1D waves of the same length, the number of dimensions is assumed to be 2. If the input consists of a single triplet wave (a wave of 3 columns), then the number of dimensions is 3.

In 2D cases the operation calculates the convex hull and produces the result in a pair of x and y waves, *W_XHull* and *W_YHull*.

In 3D cases the operation calculates the convex hull and stores it in a triplet wave *M_Hull* that describes ordered facets of the convex hull.

Flags

/C	(2D convex hull only) adds the first point to the end of the <i>W_XHull</i> and <i>W_YHull</i> waves so that the first and the last points are the same.
/E	(3D case only) if you use this flag the operation also creates a wave that lists the indices of the vertices which are not part of the convex hull, i.e., vertices which are interior to the hull. The output is in the wave <i>W_HullExcluded</i> .
/I	(3D convex hull only) use this flag to get the corresponding index of the vertex as the fourth column in the <i>M_Hull</i> wave.
/S	(3D convex hull only) use this flag if you want the resulting <i>M_Hull</i> to have NaN lines separating each triangle.
/T= <i>tolerance</i>	(3D case only) default tolerance for measuring if a point is inside or outside the convex hull is 1.0×10^{-20} . You can use any other positive value.
/V	(3D case only) if you use this flag the operation also creates a wave containing the output in a list of vertex indices. The wave <i>M_HullVertices</i> contains a row per triangle where each entry on a row corresponds to the index of the input vertex.
/Z	No error reporting.

Examples

```
Make/O/N=33 xxx=gnoise(5),yyy=gnoise(7)
Convexhull/c xxx,yyy
Display W_Yhull vs W_Xhull
AppendtoGraph yyy vs xxx
ModifyGraph mode(yyy)=3,marker(yyy)=8,rgb(W_YHull)=(0,15872,65280)
```

Convolve

Convolve [/A/C] *srcWaveName*, *destWaveName* [, *destWaveName*]...

The Convolve operation convolves *srcWaveName* with each destination wave, putting the result of each convolution in the corresponding destination wave.

Convolve is not multidimensional aware. Some multidimensional convolutions are covered by the **MatrixConvolve**, **MatrixFilter**, and **MatrixOP** operations

Flags

/A	Acausal linear convolution.
/C	Circular convolution.

Details

Convolve performs linear convolution unless the /C or /A flag is used. See the diagrams in the examples below.

Depending on the type of convolution, the destination waves' lengths may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If *srcWaveName* is real-valued, each destination wave must be real-valued, and if *srcWaveName* is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

The linear convolution equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p-m]$$

where N is the number of points in the longer of *destWaveIn* and *srcWave*. For circular convolution, the index $[p-m]$ is wrapped around when it exceeds the range of $[0, \text{numpts}(srcWave)-1]$. For acausal convolution, when $[p-m]$ exceeds the range a zero value is substituted for *srcWave* $[p-m]$. Similar operations are applied to *destWaveIn* $[m]$.

Another way of looking at this equation is that, for all p , *destWaveOut* $[p]$ equals the sum of the point-by-point products from 0 to p of the destination wave and an end-to-end reversed copy of the source wave that has been shifted to the right by p .

The following diagram shows the reversed / shifted *srcWave* that would be combined with *destWaveIn*. The points numbered 0 through 4 of the reversed *srcWave* would be multiplied with *destWaveIn* $[0\dots4]$ and summed to produce *destWaveOut* $[4]$:

For linear and acausal convolution, the destination wave is first zero-padded by one less than the length of the source wave. This prevents the “wrap-around” effect that occurs in circular convolution. The zero-padded points are removed after acausal convolution, and retained after linear convolution. The X scaling of the waves is ignored.

The convolutions are performed by transforming the source and destination waves with the Fast Fourier Transform, multiplying them in the frequency domain, and then inverse-transforming them into the destination wave(s).

The convolution is performed in segments if the resulting wave has more than 256 points and the destination wave has twice as many points as the source wave. For acausal convolution, the length of the resulting wave is considered to be $(\text{numpts}(srcWaveName) + \text{numpts}(destWaveName) - 1)$ for this calculation.

Applications

The usual application of convolution is to compute the response of a linear system defined by its impulse response to an input signal. *srcWaveName* would contain the impulse response, and the destination wave would initially contain the input signal. After the Convolve operation has completed, the destination wave contains the output signal.

Use linear convolution when the source wave contains an impulse response (or filter coefficients) where the first point of *srcWave* corresponds to no delay ($t = 0$).

Use circular convolution for the case where the data in *srcWaveName* and *destWaveName* are considered to endlessly repeat (or “wrap around” from the end back to the start), which means no zero padding is needed.

Use acausal convolution when the source wave contains an impulse response where the middle point of *srcWave* corresponds to no delay ($t = 0$).

See Also

Convolution on page III-244 for illustrated examples. **MatrixOP**.

References

A very complete explanation of circular and linear convolution can be found in sections 2.23 and 2.24 of Rabiner and Gold, *Theory and Application of Digital Signal Processing*, Prentice Hall, 1975.

CopyFile

CopyFile [*flags*][*srcFileStr*] [*as destFileOrFolderStr*]

The CopyFile operation copies a file on disk.

Parameters

srcFileStr can be a full path to the file to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If /D is specified, the source file is copied inside the folder using the source file's name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Flags

/D	Interprets <i>destFileOrFolderStr</i> as the name of (or path to) an existing folder (or "directory"). Without /D, <i>destFileOrFolderStr</i> is interpreted as the name of (or path to) a file. If <i>destFileOrFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> .
/I [=i]	Specifies the level of user interactivity. /I=0: Interactive only if one or <i>srcFileStr</i> or <i>destFileOrFolderStr</i> is not specified or if the source file is missing. (Same as if /I was not specified.) /I=1: Interactive even if <i>srcFileStr</i> is specified and the source file exists. /I=2: Interactive even if <i>destFileOrFolderStr</i> is specified. /I=3: Interactive even if <i>srcFileStr</i> is specified, the source file exists, and <i>destFileOrFolderStr</i> is specified. Same as /I only.
/M= <i>messageStr</i>	Specifies the prompt message in the Open File dialog. If /S is not used, then <i>messageStr</i> will be used for both Open File and for Save File dialogs.
/O	Overwrites any existing destination file.
/P= <i>pathName</i>	Specifies the folder to look in for the source file, and the folder into which the file is copied. <i>pathName</i> is the name of an existing symbolic path. Using /P means that both <i>srcFileStr</i> and <i>destFileOrFolderStr</i> must be either simple file or folder names, or paths relative to the folder specified by <i>pathName</i> .
/S= <i>saveMessageStr</i>	Specifies the prompt message in the Save File dialog.
/Z [=z]	Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution. /Z=0: Same as no /Z. /Z=1: Copies a file only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Copies a file if it exists or displays a dialog if it does not exist.

Variables

The CopyFile operation returns information in the following variables:

<i>v_flag</i>	Set to zero if the file was copied, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
---------------	---

<code>S_fileName</code>	Stores the full path to the file that was copied. If an error occurred or if the user cancelled, it is set to an empty string.
<code>S_path</code>	Stores the full path to the file copy. If an error occurred or if the user cancelled, it is set to an empty string.

Examples

Copy a file within the same folder using a new name:

```
CopyFile/P=myPath "afile.txt" as "destFile.txt"
```

Copy a file into subfolder using the original name (using /P):

```
CopyFile/D/P=myPath "afile.txt" as ":subfolder"
```

```
Print S_Path // prints "Macintosh HD:folder:subfolder:afile.txt"
```

Copy file into subfolder using the original name (using full paths):

```
CopyFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
```

Copy a file from one folder to another, assigning the copy a new name:

```
CopyFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
```

Copy user-selected file in any folder as destFile.txt in myPath folder (prompt to save even if destFile.txt doesn't exist):

```
CopyFile/I=2/P=myPath as "destFile.txt"
```

Copy user-selected file in any folder as destFile.txt in any folder:

```
CopyFile as "destFile.txt"
```

See Also

The **Open**, **MoveFile**, **DeleteFile**, and **CopyFolder** operations. The **IndexedFile** function. **Symbolic Paths** on page II-30.

CopyFolder

CopyFolder [*flags*][*srcFolderStr*] [*as destFolderStr*]

The CopyFolder operation copies a folder (and its contents) on disk.

Warning: *The CopyFolder command can destroy data by overwriting another folder and contents!*

When overwriting an existing folder on disk, CopyFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category. For further details see **Misc Settings** on page III-398.

If permission is denied, the folder will not be copied and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

Parameters

srcFolderStr can be a full path to the folder to be copied (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a folder inside the folder associated with *pathName*.

If Igor can not determine the location of the folder from *srcFolderStr* and *pathName*, it displays a dialog allowing you to specify the source folder.

If /P=*pathName* is given, but *srcFolderStr* is not, then the folder associated with *pathName* is copied.

destFolderStr can be a full path to the output (destination) folder (in which case /P is not needed), or a partial path relative to the folder associated with *pathName*.

An error is returned if the destination folder would be inside the source folder.

If Igor can not determine the location of the destination folder from *destFolderStr* and *pathName*, it displays a dialog allowing you to specify or create the destination folder.

If you use a full or partial path for either folder, see **Path Separators** on page III-382 for details on forming the path.

Flags

/D
Interprets *destFolderStr* as the name of (or path to) an existing folder (or directory) to copy the source folder into. Without /D, *destFolderStr* is interpreted as the name of (or path to) the copied folder.

	If <i>destFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> .
/I [=i]	Specifies the level of user interactivity. /I=0: Interactive only if the source or destination folder is not specified or if the source folder is missing. (Same as if /I was not specified.) /I=1: Interactive even if the source folder is specified and it exists. /I=2: Interactive even if <i>destFolderStr</i> is specified. /I=3: Interactive even if the source folder is specified, the source file exists, and <i>destFolderStr</i> is specified. Same as /I only.
/M=messageStr	Specifies the prompt message in the Select (source) Folder dialog. If /S is not used, then <i>messageStr</i> will be used for the Select Folder dialog and for the Create Folder dialog.
/O	Overwrite existing destination folder, if any. On Macintosh, a Macintosh-style overwrite-move is performed in which the source folder completely replaces the destination folder. On Windows, a Windows-style mix-in move is performed in which the contents of the source folder are moved into the destination folder, replacing any same-named files but leaving other files in place.
/P=pathName	Specifies the folder to look in for the source folder. <i>pathName</i> is the name of an existing symbolic path. If <i>srcFolderStr</i> is not specified, the folder associated with <i>pathName</i> is copied. Using /P means that <i>srcFolderStr</i> (if specified) and <i>destFolderStr</i> must be either simple folder names or paths relative to the folder specified by <i>pathName</i> .
/S=saveMessageStr	Specifies the prompt message in the Create Folder dialog.
/Z [=z]	Prevents procedure execution from aborting if it attempts to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution. /Z=0: Same as no /Z. /Z=1: Copies a folder only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Copies a folder if it exists or displays a dialog if it does not exist.

Variables

The CopyFolder operation returns information in the following variables:

V_flag	Set to zero if the folder was copied, to -1 if the user cancelled either the Select Folder or Create Folder dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
S_fileName	Stores the full path to the folder that was copied, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.
S_path	Stores the full path to the folder copy, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only /P=*pathName* (without *srcFolderStr*) to specify the source folder to be copied.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Examples

Copy the folder that the current experiment is stored in:

```
CopyFile/P=home as "HD:Copy Of Folder Experiment Is In"
```

Copy the Igor Extensions Folder to the Windows desktop:

```
CopyFile/D/P=Igor ":Igor Extensions" as "C:WINDOWS:Desktop"
```

Ask the user to select a folder, starting with the Igor folder, and then make a copy of that folder in the Igor Pro folder:

```
CopyFile/I=2/P=Igor as "::~Folder Copy"
```

Copy an entire disk inside a folder:

```
CopyFolder/O/D "Floppy" as "HD:Desktop Folder:Copy Into Here"
```

See Also

Open, **MoveFile**, **DeleteFile**, **MoveFolder**, **NewPath**, and **IndexedDir** operations, and **Symbolic Paths** on page II-30.

CopyScales

CopyScales [/I/P] *srcWaveName*, *waveName* [, *waveName*]...

The CopyScales operation copies the x, y, z, and t scaling, x, y, z, and t units, the data Full Scale and data units from *srcWaveName* to the other waves.

Flags

- /I Copies the x, y, z, and t scaling in inclusive format.
- /P Copies the x, y, z, and t scaling in slope/intercept format (x0, Δx format).

Details

Normally the x, y, z, and t (dimension) scaling is copied in min/max format. However, if you use /P, the dimension scaling is copied in slope/intercept format so that if *srcWaveName* and the other waves have differing dimension size (number of points if the wave is a 1D wave), then their dimension values will still match for the points they have in common. Similarly, /I uses the inclusive variant of the min/max format. See **SetScale** for a discussion of these dimension scaling formats.

If a wave has only one point, /I mode reverts to /P mode.

CopyScales copies scales only for those dimensions that *srcWaveName* and *waveName* have in common.

See Also

x, y, z, and t scaling functions.

Correlate

Correlate [/C] *srcWaveName*, *destWaveName* [, *destWaveName*]...

The Correlate operation correlates *srcWaveName* with each destination wave, putting the result of each correlation in the corresponding destination wave.

Flags

- /C Circular correlation. (See **Compatibility Note**.)

Details

Correlate performs linear correlation unless the /C flag is used.

Depending on the type of correlation, the length of the destination may increase. *srcWaveName* is not altered unless it also appears as a destination wave.

If the source wave is real-valued, each destination wave must be real-valued and if the source wave is complex, each destination wave must be complex, too. Double and single precision waves may be freely intermixed; calculations are performed in the higher precision.

The linear correlation equation is:

$$destWaveOut[p] = \sum_{m=0}^{N-1} srcWave[m] \cdot destWaveIn[p+m]$$

where N is the number of points in the longer of *destWaveIn* and *srcWave*.

For circular correlation, the index $[p+m]$ is wrapped around when it exceeds the range of $[0, numpts(destWaveIn)-1]$. For linear correlation, when $[p+m]$ exceeds the range a zero value is substituted for *destWaveIn* $[p+m]$. When m exceeds $numpts(srcWave)-1$, 0 is used instead of *srcWave* $[m]$.

Comparing this with the **Convolve** operation, which is the linear convolution:

$$destWaveOut[p] = \sum_{m=0}^{N-1} destWaveIn[m] \cdot srcWave[p-m]$$

you can see that the only difference is that for correlation the source wave is *not* reversed before shifting and combining with the destination wave.

The Correlate operation is not multidimensional aware. For details, see **Analysis on Multidimensional Waves** on page II-94 and in particular **Analysis on Multidimensional Waves** on page II-94.

Compatibility Note

Prior to Igor Pro 5, Correlate/C scaled and rotated the results improperly (the result was often rotated left by one and the X scaling was entirely negative).

Now the destination wave's X scaling is unaltered and it does not rotate the result. You can force the old behavior for compatibility with old procedures that depend on the old behavior by setting `root:V_oldCorrelationScaling=1`.

A better way to get identical Correlate/C results with all versions of Igor Pro is to use this code, which rotates the result so that $x=0$ is always the first point in *destWave*, no matter which Igor Pro version runs this code (currently, it doesn't change anything and runs extremely quickly because it does no rotation):

```
Correlate/C srcWave, destWave
Variable pointAtXEqualZero= x2pnt(destWave,0)          // 0 for Igor Pro 5
Rotate -pointAtXEqualZero,destWave
SetScale/P x, 0, DimDelta(destWave,0), "", destWave
```

Applications

A common application of correlation is to measure the similarity of two input signals as they are shifted by one another.

Often it is desirable to normalize the correlation result to 1.0 at the maximum value where the two inputs are most similar. To normalize *destWaveOut*, compute the RMS values of the input waves and the number of points in each wave:

```
WaveStats/Q srcWave
Variable srcRMS = V_rms
Variable srcLen = numpnts(srcWave)

WaveStats/Q destWave
Variable destRMS = V_rms
Variable destLen = numpnts(destWave)

Correlate srcWave, destWave          // overwrites destWave
// now normalize to max of 1.0
destWave /= (srcRMS * sqrt(srcLen) * destRMS * sqrt(destLen))
```

See Also

Convolution on page III-244 and **Correlation** on page III-247 for illustrated examples. See the **Convolve** operation for algorithm implementation details, which are identical except for the lack of source wave reversal, and the lack of the /A (acausal) flag. **MatrixOP**.

References

An explanation of autocorrelation and Power Spectral Density (PSD) can be found in Chapter 12 of Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

WaveMetrics provides Igor Technical Note 006, "DSP Support Macros" that computes the PSD with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the "WaveMetrics Procedures:Analysis:" folder.

COS

cos (angle)

The cos function returns the cosine of *angle* which is in radians. In complex expressions, *num* is complex, and `cos (num)` returns a complex value.

cosh

cosh (num)

The cosh function returns the hyperbolic cosine of *num*. In complex expressions, *num* is complex, and `cosh (num)` returns a complex value.

CountObjects

CountObjects(*sourceFolderStr*, *objectType*)

The CountObjects function returns the number of objects of the specified type in the data folder specified by the string expression.

Parameters

sourceFolderStr can be either ":" or "" to specify the current data folder. You can also use a full or partial data folder path. *objectType* should be one of the following values:

<i>objectType</i>	What CountObjects Counts
1	Waves
2	Numeric variables
3	String variables
4	Data folders

See Also

Chapter II-8, **Data Folders**, and the **GetIndexedObjName** function.

cpowi

cpowi(*num*, *ipow*)

This function is obsolete as the exponentiation operator ^ handles complex expressions with any combination of real, integer and complex arguments. See **Operators** on page IV-5. The cpowi function returns a complex number resulting from raising complex *num* to integer-valued power *ipow*. *ipow* can be positive or negative, but if it is not an integer cpowi returns (NaN, NaN).

CreateAliasShortcut

CreateAliasShortcut [*flags*][*targetFileDirStr*] [*as aliasFileStr*]

The CreateAliasShortcut operation creates an alias (*Macintosh*) or shortcut (*Windows*) file on disk. The alias can point to either a file or a folder. The file or folder pointed to is called the “target” of the alias or shortcut.

Parameters

targetFileDirStr can be a full path to the file or folder to make an alias or shortcut for, a partial path relative to the folder associated with /P=*pathName*, or the name of a file or folder in the folder associated with *pathName*.

If Igor can not determine the location of the file or folder from *targetFileDirStr* and *pathName*, it displays a dialog allowing you to specify a target file. Use /D to select a folder as the alias target, instead.

aliasFileStr can be a full path to the created alias file, a partial path relative to the folder associated with *pathName* if specified, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the alias or shortcut file from *aliasFileStr* and *pathName*, it displays a File Save dialog allowing you to create the file.

If you use a full or partial path for either *targetFileDirStr* or *aliasFileStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single path separators. See the **MoveFolder Details** section.

Flags

/D	Uses the Select Folder dialog rather than Open File dialog when <i>targetFileDirStr</i> is not fully specified.
/I [=i]	Specifies the level of user interactivity.
i=0:	Interactive only if one or <i>targetFileDirStr</i> or <i>aliasFileStr</i> is not specified or if the target file is missing. (Same as if /I was not specified.)
i=1:	Interactive even if <i>targetFileDirStr</i> is fully specified and the target file exists.
i=2:	Interactive even if <i>targetFileDirStr</i> is specified.
i=3:	Interactive even if <i>targetFileDirStr</i> is specified and the target file exists. Same as /I only.

CreationDate

/M= <i>messageStr</i>	Specifies the prompt message in the Open File or Select Folder dialog. If /S is not specified, then <i>messageStr</i> will be used for Open File (or Select Folder) and for Save File dialogs.
/O	Overwrites any existing file with the alias or shortcut file.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/S= <i>saveMessageStr</i>	Specifies the prompt message in the Save File dialog when creating the alias or shortcut file.
/Z[= <i>z</i>]	Prevents procedure execution from aborting if the procedure tries to copy a file that does not exist. Use /Z if you want to handle this case in your procedures rather than aborting execution. /Z=0: Same as no /Z. /Z=1: Creates an alias to a file or folder only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Creates an alias to a file or folder only if it exists and displaying a dialog if it does not exist.

Variables

The CreateAliasShortcut operation returns information in the following variables:

v_flag	0: Created an alias or shortcut file. -1: User cancelled any of the Open File, Select Folder, or Save File dialogs. >0: An error occurred, such as the target file does not exist.
s_path	Full path to the target file or folder. If an error occurred or if the user cancelled, it is an empty string.
s_fileName	Full path to the created alias or shortcut file. If an error occurred or if the user cancelled, it is an empty string.

Examples

Create a shortcut (*Windows*) to the current experiment, on the desktop:

```
String target= Igorinfo(1)+".pxp" // experiments are usually .pxp on Windows
CreateAliasShortcut/O/P=home target as "C:WINDOWS:Desktop:"+target
```

Create an alias (*Macintosh*) to the VDT XOP in the Igor Extensions folder:

```
String target= ":More Extensions:Data Acquisition:VDT"
CreateAliasShortcut/O/P=Igor target as ":Igor Extensions:VDT alias"
```

Create an alias to the "HD 2" disk. Put the alias on the desktop:

```
CreateAliasShortcut/D/O "HD 2" as "HD:Desktop Folder:Alias to HD 2"
```

See Also

Symbolic Paths on page II-30.

The **Open**, **MoveFile**, **DeleteFile**, and **GetFileFolderInfo** operations. The **IgorInfo** and **ParseFilePath** functions.

CreationDate

CreationDate(*waveName*)

Returns creation date of wave as an Igor date/time value, which is the number of seconds from 1/1/1904.

The returned value is valid for waves created with Igor Pro 3.0 or later. For waves created in earlier versions, it returns 0.

See Also

modDate.

Cross

Cross [/T/Z] *vectorA*, *vectorB* [, *vectorC*]

The Cross operation computes the cross products *vectorA* x *vectorB* and *vectorA* x (*vectorB* x *vectorC*). Each vector is a 1D real wave containing 3 rows. Stores the result in the wave W_Cross in the current data folder.

Flags

- /T Stores output in a row instead of a column in W_Cross.
- /Z Generates no errors for any unsuitable inputs.

CsrInfo

CsrInfo(cursorName [, graphNameStr])

The CsrInfo function returns a keyword-value pair list of information about the specified cursor (*cursorName* is A through J) in the top graph or graph specified by *graphNameStr*. It returns "" if the cursor is not in the graph.

Details

The returned string contains information about the cursor in the following format:

TNAME:traceName; ISFREE:freeNum;POINT:xPointNumber;[YPOINT:yPointNumber;] RECREATION:command;

The *traceName* value is the name of the graph trace or image to which it is attached or which supplies the x (and y) values even if the cursor isn't attached to it.

If TNAME is empty, fields POINT, ISFREE, and YPOINT are not present.

The *freeNum* value is 1 if the cursor is not attached to anything, 0 if attached to a trace or image.

The POINT value is the same value **pcsr** returns.

The YPOINT keyword and value are present only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot or when the cursor is free. It's value is the same as returned by **qcsr**.

If cursor is free, POINT and YPOINT values are fractional relative positions (see description in the **Cursor** command).

The RECREATION keyword contains the Cursor commands (including /W) necessary to regenerate the current settings.

Examples

```
Variable aExists= strlen(CsrInfo(A)) > 0           // A is a name, not a string
Variable bIsFree= NumberByKey("ISFREE",CsrInfo(B,"Graph0"))
```

See Also

The **Cursor** operation and the **hcsr**, **pcsr**, **qcsr**, **vcscr**, **xcscr**, and **zcscr** functions. **Cursors — Moving Cursor Calls Function** on page IV-220.

CsrWave

CsrWave(cursorName [, graphNameStr [, wantTraceName]])

The CsrWave function returns a string containing the name of the wave the specified cursor (A through J) is on in the top (or named) graph. If the optional *wantTraceName* is nonzero, the trace name is returned. A trace name is the wave name with optional instance notation (see **ModifyGraph (traces)**).

Details

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrWave for the purpose of passing the wave name to other procedures, you should use the **CsrWaveRef** function instead. Use CsrWave if you want the name of the wave to use in an annotation or a notebook.

Examples

```
String waveCursorAIsOn = CsrWave(A)                // not CsrWave("A")
String waveCursorBIsOn = CsrWave(B,"Graph0")        // in specified graph
String traceCursorBIsOn = CsrWave(B,"",1)           // trace name in top graph
```

CsrWaveRef

CsrWaveRef(cursorName [, graphNameStr])

The CsrWaveRef function returns a wave reference to the wave the specified cursor (A through J) is on in the top (or named) graph.

Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrWaveRef should be used in place of the CsrWave() string function to work properly with data folders.

Examples

```
Print CsrWaveRef(A)[50]           // not CsrWaveRef("A")
Print CsrWaveRef(B,"Graph0")[50] // in specified graph
```

See Also

See **Wave Reference Functions** on page IV-143.

CsrXWave

CsrXWave(cursorName [, graphNameStr])

The CsrXWave function returns a string containing the name of the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

Details

CsrXWave returns the null string (" ") if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as **Display theWave vs anotherWave**).

The name of a wave by itself is not sufficient to identify the wave because it does not specify what data folder contains the wave. Thus, if you are calling CsrXWave for the purpose of passing the wave name to other Igor procedures, you should use the **CsrXWaveRef** function instead. Use CsrXWave if you want the name of the wave to use in an annotation or a notebook.

Examples

```
Display ywave vs xwave
ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.
Cursor A ywave,0
Print CsrXWave(A)           // prints xwave
```

CsrXWaveRef

CsrXWaveRef(cursorName [, graphNameStr])

The CsrXWaveRef function returns a wave reference to the wave supplying the X coordinates for an XY plot of the Y wave the specified cursor (A through J) is attached to in the top (or named) graph.

Details

The wave reference can be used anywhere Igor is expecting the name of a wave (not a string containing the name of a wave).

CsrXWaveRef returns a null reference (see **WaveExists**) if the wave the cursor is on is not plotted versus another wave providing the X coordinates (that is, if the wave was not plotted with a command such as **Display theWave vs anotherWave**). CsrXWaveRef should be used in place of the CsrXWave string function to work properly with data folders.

Examples

```
Display ywave vs xwave
ywave supplies the Y coordinates and xwave supplies the X coordinates for this XY plot.
Cursor A ywave,0
Print CsrXWaveRef(A)[50]           // prints value of xwave at point #50
```

See Also

See **Wave Reference Functions** on page IV-143.

CTabList

CTabList()

The CTabList string function returns a semicolon-separated list of the names of built-in color tables. This can be useful when creating pop-up menus in control panels.

Color tables available through version 4:

Grays	Rainbow	YellowHot	BlueHot	BlueRedGreen
RedWhiteBlue	PlanetEarth	Terrain		

Additional color tables added for version 5:

Grays256	Rainbow256	YellowHot256	BlueHot256	BlueRedGreen256
RedWhiteBlue256	PlanetEarth256	Terrain256	Grays16	Rainbow16
Red	Green	Blue	Cyan	Magenta
Yellow	Copper	Gold	CyanMagenta	RedWhiteGreen
BlueBlackRed	Geo	Geo32	LandAndSea	LandAndSea8
Relief	Relief19	PastelsMap	PastelsMap20	Bathymetry9
BlackBody	Spectrum	SpectrumBlack	Cycles	Fiddle
Pastels				

Additional color tables added for version 6:

RainbowCycle	Rainbow4Cycles	GreenMagenta16	dBZ14	dBZ21
Web216	BlueGreenOrange	BrownViolet	ColdWarm	Mocha
VioletOrangeYellow	SeaLandAndFire			

See Also

See **Color Tables** on page II-327 and **ColorTab2Wave**.

CtrlBackground

CtrlBackground [*key* [= *value*]]...

The CtrlBackground operation controls the background task.

Parameters

dialogsOK=1 or 0	If 1, your task will be allowed to run while an Igor dialog is present. This can potentially cause crashes unless your task is well-behaved.
noBurst=1 or 0	Normally (or noBurst=0), your task will be called at maximum rate if a delay causes normal run times to be missed. Using noBurst=1, will suppress this burst catch up mode.
period= <i>deltaTicks</i>	Sets the minimum number of ticks that must pass between invocations of the background task.
start[= <i>startTicks</i>]	Starts the background task (designated by SetBackground) when the tick count reaches <i>startTicks</i> . If you omit <i>startTicks</i> the task starts immediately.
stop	Stops the background task.

See Also

The **BackgroundInfo**, **SetBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Task** on page IV-211.

CtrlNamedBackground

CtrlNamedBackground *keyword* = *value* [, *keyword* = *value* ...]

The CtrlNamedBackground operation creates and controls named background tasks. Unlike the unnamed background task, you can create unlimited numbers of named tasks. However, many of the same issues that affect unnamed background tasks apply to named tasks.

CtrlNamedBackground

Parameters

burst [= <i>b</i>]	Enable burst catch up mode (off by default, <i>b</i> =0). When on (<i>b</i> =1), the task is called at the maximum rate if a delay misses normal run times.
kill [= <i>k</i>]	Stops and releases task memory for reuse (<i>k</i> =1; default) or continues (<i>k</i> =0).
period= <i>deltaTicks</i>	Sets the minimum number of ticks (<i>deltaTicks</i>) that must pass between background task invocations.
proc= <i>funcName</i>	Specifies name of a background user function (see Details). To apply settings to or obtain status about all named tasks, use <i>funcName</i> =_all_.
start [= <i>startTicks</i>]	Starts when the tick count reaches <i>startTicks</i> . A task starts immediately without <i>startTicks</i> .
status	Returns background task information in the S_info string variable.
stop [= <i>s</i>]	Stops the background task (<i>s</i> =1; default) or continues (<i>s</i> =0).

Details

The user function you specify via the proc parameter must have the following format:

```
Function myFunc(s)
    STRUCT WMBBackgroundStruct &s
    ...
```

The members of the WMBBackgroundStruct are:

Base WMBBackgroundStruct Structure Members

Member	Description
char name[MAX_OBJ_NAME+1]	Background task name.
uint32 curRunTicks	Tick count when task was called.
uint32 started	TRUE when CtrlNamedBackground start is issued. You may clear or set to desired value.
uint32 nextRunTicks	Precomputed value for next run but user functions may change this.

You may also specify a user function that takes a user-defined STRUCT as long as the first elements of the structure match the WMBBackgroundStruct or, preferably, if the first element is an instance of WMBBackgroundStruct. Use the started field to determine when to initialize the additional fields.

If you specify a user-defined structure that matches the first fields rather than containing an instance of WMBBackgroundStruct, then your function will fail if, in the future, the size of the built-in structure changes. The value of MAX_OBJ_NAME is 31 but this may also change.

Your function should return zero unless it wants to stop in which case it should return 1.

You can call CtrlNamedBackground within your background function. You can even switch to a different function if desired.

Use the status parameter to return background task information via the S_info variable, which has the format:

NAME:*name*;PROC:*fname*;RUN:*r*;PERIOD:*p*;NEXT:*n*;QUIT:*q*;FUNCERR:*e*;

When parsing S_info, do not rely on the number of key-value pairs or their order. RUN, QUIT, and FUNCERR values are 1 or 0, NEXT is the tick count for the next firing of the task. QUIT is set to 1 when your function returns a nonzero value and FUNCERR is set to 1 if your function could not be used for some reason.

Examples

For the procedure window of a new experiment:

```
Structure myStruct
    STRUCT WMBBackgroundStruct b
    Variable extra
EndStructure

Function myFunc(s)
    STRUCT WMBBackgroundStruct &s
    if( CmpStr(s.name,"fred") == 0 )
        print "F"
    else
        print "S"
    endif
```

```

    return 0
End
Function xmyFunc(s)
    STRUCT myStruct &s
    if( s.b.started )
        s.extra= 0                // initialize extra field
        s.b.started= 0            // just once
    endif
    if( CmpStr(s.b.name,"fred") == 0 )
        s.extra += 1
        print "F",s.extra
    else
        s.extra += 1
        print "S",s.extra
    endif
    return 0
End
Function startback()
    CtrlNamedBackground fred,period=60,proc=myFunc
    CtrlNamedBackground sam,period=40,proc=myFunc
    CtrlNamedBackground _all_,start
End

```

Then on the command line, execute:

```
startback()
```

Now, as the tasks print F and S to the history, edit the procedure window and swap the names of myFunc and xmyFunc and then click the compile button. Notice the change is printout due the use of the new version of myFunc.

Check the task status by executing:

```
CtrlNamedBackground _all_,status;print S_info
```

To stop the task execute:

```
CtrlNamedBackground _all_,stop=1
```

See Also

Background Task on page IV-211.

CtrlFIFO

CtrlFIFO FIFOName [, key = value]...

The CtrlFIFO operation controls various aspects of the named FIFO.

Parameters

close	Closes the FIFO's output or review file (if any).
deltaT=dt	Documents the data acquisition rate.
doffset=dataOffset	Used only with rdfile. Offset to data. If not provided offset is zero.
dsize=dataSize	Used only with rdfile. Size of data in bytes. If not provided, then data size is assumed to be the remainder of file. If this assumption is not valid then unexpected results may be observed.
file=oRefNum	File reference number for the FIFO's output file. You obtain this reference number from the Open operation used to create the file.
note=noteStr	Stores the note string in the file header. It is limited to 255 characters.
rdfile=rRefNum	Like rfile but for review of raw data (use Open/R command). Channel data must match raw data in file. Offset from start of file to start of data can be provided using doffset given in same command. If data does not extend all the way to the end of the file, then the number of bytes of data can be provided using dsize in the same command.
rfile=rRefNum	File reference number for the FIFO's review file. Use a review file when you are using a FIFO to review existing data. Obtain the reference number from the Open/R operation used to open the file. File may be either unified header/ data or a split format where the header contains the name of a file containing the raw data.

Cursor

size=s	Sets number of chunks in the FIFO. The default is 10000. A chunk of data consists of a single data point from each of the FIFO's channels.
start	Starts the FIFO running by setting the time/ date in the FIFO header, writing the header to the output file and marking the FIFO active.
stop	Stops the FIFO by flushing data to disk and marking the FIFO as inactive.
swap	Used only with rdfile. Indicates that the raw data file requires byte-swapping when it is read. This would be the case if you are running on a Macintosh, reading a binary file from a PC, or vice versa.

Details

Once start has been issued, the FIFO can accept no further commands except stop.

The FIFO must be in the valid state for you to access its data (using a chart control or using the **FIFO2Wave** operation). When you create a FIFO, using **NewFIFO**, it is initially invalid. It becomes valid when you issue the start command via the **CtrlFIFO** operation. It remains valid until you change a FIFO parameter using **CtrlFIFO**.

FIFOs are used for data acquisition.

See Also

The **NewFIFO** and **FIFO2Wave** operations, and **FIFOs and Charts** on page IV-208.

Cursor

Cursor [*flags*] *cursorName* *traceName* *x_value*

Cursor /F [*flags*] *cursorName* *traceName* *x_value*, *y_value*

Cursor /K [/W=*graphName*] *cursorName*

Cursor /I [/F] [*flags*] *cursorName* *imageName* *x_value*, *y_value*

Cursor /M [*flags*] *cursorName*

The Cursor operation moves the cursor specified by *cursorName* onto the named trace at the point whose X value is *x_value*. or the coordinates of an image pixel or free cursor position at *x_value* and *y_value*.

Parameters

cursorName is one of ten cursors A through J.

Flags

/A=a	Activates (<i>a</i> =1) or deactivates (<i>a</i> =0) the cursor. Active cursors move with arrow keys or the cursor panel.
/C=(<i>r,g,b</i>)	Sets the cursor color (default is black). <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color of the waves as an integer from 0 to 65535.
/F	Cursor roams free. The trace or image provides the axis pair that defines x and y coordinates for the setting and readout. Use /P to set in relative coordinates, where 0,0 is the top left corner of the rectangle defined by the axes and 1,1 is the right bottom corner.
/H= <i>h</i>	Specifies crosshairs on cursors. <i>h</i> =0 Full crosshairs off. <i>h</i> =1 Full crosshairs on. <i>h</i> =2 Vertical hairline. <i>h</i> =3 Horizontal hairline.
/I	Places cursor on specified image.
/K	Removes the named cursor from the top graph.
/L= <i>lStyle</i>	Line style for crosshairs (full or small). <i>lStyle</i> =0: Solid lines. <i>lStyle</i> =1: Alternating color dash.
/M	Modifies properties without having to specify trace or image coordinates. Does not work with the /F or /I flags.
/P	Interpret <i>xNum</i> as a point number rather than an X value.
/S=s	Sets cursor style. <i>s</i> =0: Original square or circle.

s=1: Small crosshair with letter.
s=2: Small crosshair without letter.
/W=graphName Specifies a particular named graph window or subwindow. When omitted, action will affect the active window or subwindow.
 When identifying a subwindow with *graphName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Usually *traceName* is the same as the name of the wave displayed by that trace, but it could be a name in instance notation. See **ModifyGraph (traces)** and **Instance Notation** on page IV-16 for discussions of trace names and instance notation.

A string containing *traceName* can be used with the \$ operator to specify the trace name.

x_value is an X value in terms of the X scaling of the wave displayed by *traceName*. If *traceName* is graphed as an XY pair, then *x_value* is *not* the same as the X axis coordinate. Since the X scaling is ignored when displaying an XY pair in a graph, we recommend you use the /P flag and use a point number for *x_value*.

cursorName is a name, *not* a string.

To get a cursor readout, choose ShowInfo from the Graph menu.

Moving a cursor in a macro or function does not immediately erase the old cursor. DoUpdate has to be explicitly called.

Examples

```
Display myWave           // X coordinates from X scaling of myWave
Cursor A, myWave, leftx(myWave) //cursor A on first point of myWave
AppendToGraph yWave vs xWave //X coordinates from xWave, not X scaling
Cursor/P B,yWave,numpts(yWave)-1 //cursor B on last point of yWave
DoUpdate                // erase any old A or B cursors
```

See Also

The **DoUpdate** and **ShowInfo** operations and the **CsrInfo**, **CsrWave**, **CsrWaveRef**, **CsrXWave**, **CsrXWaveRef**, **hcsr**, **pcsr**, **qcsr**, **vcsr**, **xcsr**, and **zcscr** functions. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

CursorStyle

CursorStyle

CursorStyle is a procedure subtype keyword that puts the name of the procedure in the “Style function” submenu of the Cursor Info pop-up menu. It is automatically used when Igor creates a cursor style function. To create a cursor style function, choose “Save style function” in the “Style function” submenu of the Cursor Info pop-up menu.

CurveFit

CurveFit [*flags*] *type*, [**kwCWave=coefWaveName,**] *waveName* [*parameters*]

The CurveFit operation fits one of several built-in functions to your data (for user-defined fits, see the **FuncFit** operation). When with CurveFit and built-in fit functions, automatic initial guesses will provide a good starting point in most cases.

The results of the fit are returned in a wave, by default W_coef. In addition, the results are put into the system variables K0, K1 ... K_n but the use of the system variables is limited and considered obsolete.

You can specify your own wave for the coefficient wave instead of W_coef using the kwCWave keyword.

Virtually all waves specified to the CurveFit operation can be a sub-range of a larger wave using the same sub-range syntax as the Display operation uses for graphing. See **Wave Subrange Details** on page V-82.

See Chapter III-8, **Curve Fitting** for detailed information including the use of the Curve Fit dialog.

Flags

/B=pointsPerCycle Used when *type* is sin; *pointsPerCycle* is the estimated number of data points per sine wave cycle. This helps provide initial guesses for the fit. You may need to try a few different values on either side of your estimated points/cycle.

/C	Makes constraint matrix and vector. This only applies if you use the <code>/C=constraintSpec</code> parameter to specify constraints (see below). Creates the <code>M_FitConstraint</code> matrix and the <code>W_FitConstraint</code> vector. For more information, see Fitting with Constraints on page III-195.
/G	Use values in variables <code>K0</code> , <code>K1</code> ... <code>Kn</code> as starting guesses for a fit. If you specify a coefficient wave with the <code>kwCWave</code> keyword, the starting guesses will be read from the coefficient wave.
/H="hhh..."	Specifies coefficients to hold constant. <i>h</i> is 1 for coefficients to hold, 0 for coefficients vary. For example, <code>/H="100"</code> holds <code>K0</code> constant, varies <code>K1</code> and <code>K2</code> .
/K={constants}	Sets values of constants (not fit coefficients) in certain fitting functions. For instance, the <code>exp_XOffset</code> function contains an <code>X</code> offset constant. Built-in functions will set the constant automatically, but the automatic value can be overridden using this flag. <i>constants</i> is a list of constant values, e.g., <code>/K={1,2,3}</code> . The length of the list must match the number of constants used by the chosen fit function. This flag is not currently supported by the Curve Fit dialog. Use the <code>To Cmd</code> button and add the flag on the command line.
/L=destLen	Sets the length of the wave created by the <code>AutoTrace</code> feature, that is, <code>/D</code> without destination wave (see the <code>/D</code> parameter above). The length of the wave <code>fit_waveName</code> will be set to <code>destLen</code> . This keyword also sets the lengths of waves created for confidence and prediction bands.
/M	Generates the covariance matrix, the waves <code>CM_Kn</code> , where <i>n</i> is from 0 (for <code>K0</code>) to the number of coefficients minus one.
/M=doMat	Generates the covariance matrix. If <code>doMat=2</code> , the covariance matrix is put into a 2D matrix wave called <code>M_Covar</code> . If <code>doMat=1</code> or is missing, the covariance matrix is generated as the 1D waves <code>CM_Kn</code> , where <i>n</i> is from 0 (for <code>K0</code>) to the number of coefficients minus one. If <code>doMat=0</code> , the covariance matrix is not generated. <code>doMat=1</code> is included for compatibility with previous versions; it is better to use <code>doMat=2</code> .
/N	Suppresses updates during the fit. This can make the curve fit much faster; all graphs, tables, etc. will update after the fit finishes.
/NTHR = nthreads	Uses multithreaded code in <i>nthreads</i> threads for built-in and standard user-defined fitting functions. Values for <i>nthreads</i> are: <ul style="list-style-type: none">0: Selects Auto mode, which uses a number of threads equal to the number of processors in your computer (see ThreadProcessorCount).1: Uses one thread, that is, it is not multithreaded. Overhead for multithreaded code makes it pretty much useless for built-in functions. For user-defined functions you can get almost double the speed on a two-processor computer; the benefit will depend on how fast your fit function is, and how many data points you are fitting.
/O	Generates only initial guesses; doesn't actually do the fit.
/ODR=fitMethod	Selects a fitting method. Values for <i>fitMethod</i> are: <ul style="list-style-type: none">0: Default Levenberg-Marquardt least-squares method using old code.1: Trust-region Levenberg-Marquardt ordinary least-squares method implemented using <code>ODRPACK95</code> code. See Curve Fitting References on page III-227.2: Trust-region Levenberg-Marquardt least orthogonal distance method implemented using <code>ODRPACK95</code> code. This method is appropriate for fitting when there are measurement errors in the independent variables, sometimes called "errors in variables fitting", "random regressor models," or "measurement error models".3: Implicit fit. No dependent variable is specified; instead fitting attempts to adjust the fit coefficients such that the fit function returns zero for all dependent variables.

Implicit fitting will be of almost no use with the built-in fitting functions. Instead, use **FuncFit** and a user-defined fit function designed for an implicit fit.

/Q

Prevents results from being printed in history.

/TBOX = *textboxSpec*

Adds an annotation to the graph containing the fit data (see the **TextBox** operation, or Chapter III-2, **Annotations**). The textbox contains a customizable set of information about the fit. The argument *textboxSpec* is a bitfield to select various elements to be included in the textbox:

<i>textboxSpec</i>	Selects This Element
1	Title "Curve Fit Results"
2	Date
4	Time
8	Fit Type (Least Squares, ODR, etc.)
16	Fit function name
32	Model Wave, the autodegradation wave (includes a symbol for the trace if appropriate)
64	Y Wave, with trace symbol
128	X Wave
256	Coefficient value report
512	Include errors in the coefficient value report

Request inclusion of various parts by adding up the values for each part you want. Setting *textboxSpec* to zero will remove the textbox. Default is *textboxSpec* = 0.

/X

Sets the X scaling of the auto-trace destination wave to match the appropriate X axis on the graph when the Y data wave is on the top graph. This is useful when you want to extrapolate the curve outside the range of X data being fit.

/W=*wait*

Specifies behavior for dismissing the curve fit dialog window.

wait=1 Wait till user clicks OK button before dismissing curve fit window.
Default behavior from the command line or dialog.

wait =0 Do not wait. Default behavior from a procedure.

Fit Types

type is one of the built-in curve fit function types:

gauss	Gaussian peak: $y = K_0 + K_1 \exp \left[-\left(\frac{x - K_2}{K_3} \right)^2 \right]$.
lor	Lorentzian peak: $y = K_0 + \frac{K_1}{(x - K_2)^2 + K_3}$.
exp	Exponential: $y = K_0 + K_1 \exp(-K_2 x)$.
dblexp	Double exponential: $y = K_0 + K_1 \exp(-K_2 x) + K_3 \exp(-K_4 x)$.
sin	Sinusoid: $y = K_0 + K_1 \sin(K_2 x + K_3)$.
line	Line: $y = K_0 + K_1 x$.
poly <i>n</i>	Polynomial: $y = k_0 + K_1 x + K_2 x^2 + \dots$. <i>n</i> is from 3 to 20. <i>n</i> is the number of terms or the degree plus one.
hillequation	Hill's Equation: $y = K_0 + \frac{(K_1 - K_0)}{1 + (K_3/x)^{K_2}}$.

This is a sigmoidal function. Note that X values must be greater than 0.

sigmoid
$$y = K_0 + \frac{K_1}{1 + \exp(K_2 - x \cdot K_3)}.$$

power Power law: $y = K_0 + K_1 x^{K_2}$. Note that X values must be greater than 0.

lognormal Log normal: $y = K_0 + K_1 \exp\left[-\left(\frac{\ln(x \cdot K_2)}{K_3}\right)^2\right]$. X values must be greater than 0.

gauss2D Two-dimensional Gaussian:

$$z = K_0 + K_1 \exp\left[\frac{-1}{2(1 - K_6^2)}\left(\left(\frac{x - K_2}{K_3}\right)^2 + \left(\frac{y - K_4}{K_5}\right)^2 - \frac{2K_6(x - K_2)(y - K_4)}{K_3 K_5}\right)\right].$$

The cross-correlation coefficient (K_6) must be between -1 and 1. This coefficient is automatically constrained to lie in that range. If you are confident that the correlation is zero, it may greatly speed the fit to hold it at zero.

poly2D n Two-dimensional polynomial: $z = K_0 + K_1 x + K_2 y + K_3 x^2 + K_4 xy + K_5 y^2 + \dots$ where n is the degree of the polynomial. All terms up to degree n are included, including cross terms. For instance, degree 3 terms are x^3 , $x^2 y$, xy^2 , and y^3 .

exp_XOffset Exponential: $y = K_0 + K_1 \exp(-(x - x_0) \cdot K_2)$.

x_0 is a constant; by default it is set to the minimum x value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors that can afflict the exp function.

dblexp_XOffset Double exponential:

$$y = K_0 + K_1 \exp(-(x - x_0) \cdot K_2) + K_3 \exp(-(x - x_0) \cdot K_{4(2)}).$$

x_0 is a constant; by default it is set to the minimum x value involved in the fit. Inclusion of x_0 prevents problems with floating-point roundoff errors that can afflict the exp function.

waveName is the wave containing the Y data to be fit to the selected function *type*. You can fit to a subrange of the wave by supplying (*startX,endX*) after the wave name. Though not shown in the syntax description, you can also specify the subrange in points by supplying [*startP,endP*] after the wave name. See **Wave Subrange Details** on page V-82 for more information on subranges of waves in curve fitting.

If you are using one of the two-dimensional fit functions (gauss2D or poly2D) either *waveName* must name a matrix wave or you must supply a list of X waves via the /X flag.

Fit Parameters

Note: All fit parameters must follow *waveName* in the command. All fit parameter flags must appear immediately after the operation name (CurveFit).

/A=*appendResid* *appendResid*=1 (default) appends the automatically-generated residual to the graph and *appendResid*=0 prevents appending (see /R[=*residwaveName*]). With *appendResid*=0, the wave is generated and filled with residual values, but not appended to the graph.

/C=*constraintSpec* Applies linear constraints during curve fitting. Constraints can be in the form of a text wave containing constraint expressions (/C=*textWaveName*) or a suitable matrix and vector (/C={*constraintMatrix*, *constraintVector*}). See **Fitting with Constraints** on page III-195. **Note:** Constraints are not available for the built-in line, poly and poly2D fit functions. To apply constraints to these fit functions you must create a user-defined fit function.

/D [=*destwaveName*] *destwaveName* is evaluated based on the equation resulting from the fit. *destwaveName* must have the same length as *waveName*.

If only /D is specified, an automatically named wave is created. The name is based on the *waveName* with "fit_" as a prefix. This automatically named wave will be appended (if necessary) to the top graph if *waveName* is graphed there. The X scaling of the fit_ wave is set from the range of x data used during the fit.

By default the length of the automatically-created wave is 200 points (or 2 points for a straight line fit). This can be changed with the /L flag.

If *waveName* is a 1D wave displayed on a logarithmic X axis, Igor also creates an X wave with values exponentially spaced. The name is based on *waveName* with "fitX_" as a prefix.

/F={*confLevel*, *confType* [, *confStyleKey* [, *waveName*...]]}

Calculates confidence intervals for a confidence level of *confLevel*. The value of *confLevel* must be between 0 and 1 corresponding to confidence levels of 0 to 100 per cent.

confType selects what to calculate:

- 1: Confidence bands for the model.
- 2: Prediction bands for the model.
- 4: Confidence intervals for the fit coefficients.

These values can be added together to select multiple options. That is, to select both a confidence band and fit coefficient confidence intervals, set *confType* to 5.

Confidence and prediction bands can be shown as waves contouring a given confidence level (use "Contour" for *confStyleKey*) or as error bars (use "ErrorBar" for *confStyleKey*). The default is Contour.

If no waves are specified, waves to contain the results are automatically generated and appended to the top graph (if the top graph contains the fitted data). See **Confidence Band Details** for details on the waves for confidence bands. **Note:** Confidence bands are not available for multivariate curve fits.

/I [=weightType]

If *weightType* is 1, the weighting wave (see /W parameter) contains standard deviations. If *weightType* is 0, the weighting wave contains reciprocal of the standard deviation. If the /I parameter is not present, the default is /I=0.

/M=maskWaveName

Specifies that you want to use the wave named *maskWaveName* to select points to be fit. The mask wave must match the dependent variable wave in number of points and dimensions. Setting a point in the mask wave to zero or NaN (blank in a table) eliminates that point from the fit.

/R [=residwaveName]

Calculates elements of *residwaveName* by subtracting model values from the data values. *residwaveName* must have the same length as *waveName*.

If only /R is specified, an automatically named wave is created with the same number of points as *waveName*. The name is based on *waveName* with "Res_" as a prefix.

The automatically created residual wave will be appended (if necessary) to the top graph if *waveName* is graphed there. The residual wave is appended to a new free axis named by prepending "Res_" to the name of the vertical axis used for plotting *waveName*. To the extent possible, the new free axis is formatted nicely.

If the graph containing the data to be fit has very complex formatting, you may not wish to automatically append the residual to the graph. In this case, use /A=0, as documented above.

/W=wghtwaveName

wghtwaveName contains weighting values applied during the fit, and must have the same length as *waveName*. These weighting values can be either the reciprocal of the standard errors, or the standard errors. See the /I parameter above for details.

/X=xwaveName

The X values for the data to fit come from *xwaveName*, which must have the same length and type as *waveName*.

If you are fitting to one of the two-dimensional fit functions and *waveName* is a matrix wave, *xwaveName* supplies independent variable data for the X dimension. In this case, *xwaveName* must name a 1D wave with the same number of rows as *waveName*.

/X={xwave1, xwave2}

For fitting to one of the two-dimensional fit functions when *waveName* is a 1D wave. *xwave1* and *xwave2* must have the same length as *waveName*.

/Y=ywaveName

For fitting using one of the 2D fit functions if *waveName* is a matrix wave. *ywaveName* must be a 1D wave with length equal to the number of columns in *waveName*.

Fit Parameters for Nonzero /ODR

/XW=xWeightWave

/XW={xWeight1, xWeight2}

/ODR=2 or 3 only.

Specifies weighting values for the independent variables using *xWeightWave*, which must have the same length as *waveName*. When fitting to one of the multivariate fit functions such as poly2D or Gauss2D, you must supply a weight wave for each independent variable using the second form.

Weighting values can be either the reciprocal of the standard errors, or the standard errors. The choice of standard error or reciprocal standard error must be the same for both /W and /XW. See the /I flag for details.

/XHLD=*holdWave*

/XHLD={*holdWave1*, *holdWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to hold the values of the independent variables fixed during orthogonal distance regression. The waves must match the input X data; a one in a wave element fixes the value of the corresponding X value.

/CMAG=*scaleWave*

Specifies a wave that indicates the expected scale of the fit coefficients at the solution. If different coefficients have very different orders of magnitude of expected values, this can improve the efficiency and accuracy of the fit.

/XD=*xDestWave*

/XD={*xDestWave1*, *xDestWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the fitted values of the independent variables during a least orthogonal distance regression.

/XR=*xResidWave*

/XR={*xResidWave1*, *xResidWave2*}

/ODR=2 or 3 only.

Specifies a wave or waves to receive the differences between fitted values of the independent variables and the starting values during a least orthogonal distance regression. That is, they will be filled with the X residuals.

Details

CurveFit gets initial guesses from the Kn system variables when user guesses (/G) are specified, unless a coefficient wave is specified using the kwCWave keyword. Final curve fit parameters are written into a wave name W_coef, unless you specify a coefficient wave with the kwCWave keyword.

Other output waves are M_Covar (see the /M flag), M_FitConstraint and W_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-195) and W_sigma.

For compatibility with earlier versions of Igor, the parameters are also stored in the system variables Kn. This can be a source of confusion. We suggest you think of W_coef as the **output** coefficients and Kn as **input** coefficients that get overwritten.

Other output waves are M_Covar (see the /M flag), M_FitConstraint and W_FitConstraint (see /C parameter and **Fitting with Constraints** on page III-195), W_sigma. If you have selected coefficient confidence limits using the /F parameter, a wave called W_ParamConfidenceInterval is created with the confidence intervals for the fit coefficients.

CurveFit stores other curve fitting statistics in variables whose names begin with "V_". CurveFit also looks for certain V_ variables which you can use to modify its behavior. These are discussed in **Special Variables for Curve Fitting** on page III-199.

When fitting with /ODR=nonzero, fitting with constraints is limited to simple "bound constraints." That is, you can constrain a fit coefficient to be greater than or less than some value. Constraints involving combinations of fit coefficients are supported only with /ODR=0. The constraints are entered in the same way, using an expression like K0>1.

Wave Subrange Details

Almost any wave you specify to CurveFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-267 for details). However, the Display command allows only one dimension to have a range (multiple elements from the dimension); if a multidimensional wave is appropriate for CurveFit, you may use a range for more than one dimension.

Some waves must have the same number of points as other waves. For instance, a one-dimensional Y wave must have the same number of points as any X waves. Thus, if you use a subrange for an X wave, the

number of points in the subrange must match the number of points being used in the Y wave (but see **Subrange Backward Compatibility** on page V-83 for a complication to this rule).

A common use of wave subranges might be to package all your data into a single multicolumn wave, along with the residuals and model values. For a univariate fit, you might need X and Y waves, plus a destination (model) wave and a residual wave. You can achieve all of that using a four-column wave. For example:

```
Make/D/N=(100, 4) Data
... fill column zero with X data and column one with Y data ...
CurveFit poly 3, Data[][1] /X=Data[][0]/D=Data[][2]/R=Data[][3]
```

Note that because all the waves are full columns from a single multicolumn wave, the number of points is guaranteed to be the same.

The number of points used for X waves (*xwaveName* or {*xwave1*, *xwave2*, ...}), weighting wave (*wghtwaveName*), mask wave (*maskWaveName*), destination wave (*destwaveName*) and residual wave (*residwaveName*) must be the same as the number of points used for the Y wave (*waveName*). If you specify your own confidence band waves (/F flag) they must match the Y wave; you cannot use subranges with confidence band waves. If you set /ODR = nonzero, the X weight, hold, destination and residuals waves must match the Y wave.

The total number of points in each wave does not need to match other waves, just the number of points in the specified subrange.

When fitting to a univariate fit function (that includes almost all the fit types) the Y wave must have effectively one dimension. That means the Y wave must either be a 1D wave, or it must have a subrange that makes the data being used one dimensional. For instance:

```
Make/N=(100,100) Ydata           // 2D wave
CurveFit gauss Ydata[][0]         // OK- a single column is one-dimensional
CurveFit gauss Ydata[2][]         // OK- s single row is one-dimensional
CurveFit gauss Ydata              // not OK- Ydata is two-dimensional
CurveFit gauss Ydata[][0,1]       // not OK- two columns makes 2D subrange
```

When fitting a multivariate function (**poly2D** or **Gauss2D**) you have the choice of making the Y data either one-dimensional or two-dimensional. If it is one-dimensional, then you must be fitting XYZ (or Y,X1,X2) triplets. In that case, you must provide a one-dimensional Y wave and two one-dimensional X waves, or 2 columns from a multicolumn wave. For instance:

These are OK:

```
Make/N=(100,3) myData
CurveFit Gauss2D myData[][0] /X={myData[][1],myData[][2]}
CurveFit Gauss2D myData[][0] /X=myData[][1,2]
```

These are not OK:

```
CurveFit Gauss2D myData /X={myData[][1],myData[][2]} // 2D Y wave with 1D X waves
CurveFit Gauss2D myData[][0] /X=myData                // too many X columns
```

If you use a 2D Y wave, the X1 and X2 data can come from the grid positions and the Y wave's X and Y index scaling, or you can use one-dimensional waves or wave subranges to specify the X1 and X2 positions of the grid:

```
Make/N=(20,30) yData
CurveFit Gauss2D yData           //OK- 2D Y data, X1 and X2 from scaling
Make/N=20 x1Data
Make/N=30 x2Data
// OK: 2D effective Y data, matching 1D X and Y flags
CurveFit Gauss2D yData[0,9][0,19] /X=x1Data[0,9]/Y=x2data[10,29]
// OK: effective 2D Y data
Make/N=(10,20,3) Y data
CurveFit Gauss2D yData[][0]
```

There are, of course, lots of possible combinations, too numerous to enumerate.

Subrange Backward Compatibility

Historically, a Y wave could have a subrange. The same subrange applied to all other waves. For backward compatibility, if you use a subrange with the Y wave only, and other waves lack a subrange, these other waves must have either: 1) The same total number of points as the total number of points in the Y wave in which case the Y wave subrange will be applied; or 2) The same total number of points as the Y wave's subrange.

In addition, the Y wave can take a subrange in parentheses to indicate that the subrange refers to the Y wave's scaled indices (X scaling). If you use parentheses to specify an X range, you must satisfy the old

subrange rules: All waves must have the same number of points. Subrange is allowed for the Y wave only. The Y wave subrange is applied to all other waves.

Confidence Band Details

Automatic generation of confidence and prediction bands occurs if the `/F={...}` parameter is used with no wave names. One to four waves are generated, or you can specify one to four wave names yourself depending on the *confKind* and *confStyle* settings.

Waves auto-generated by `/F={confLevel, confKind, confStyle}`:

<i>confKind</i>	<i>confStyle</i>	What You Get	Auto Wave Names
1	"Contour"	upper and lower confidence contours	UC_ <i>dataName</i> , LC_ <i>dataName</i>
2	"Contour"	upper and lower prediction contours	UP_ <i>dataName</i> , LP_ <i>dataName</i>
3	"Contour"	upper and lower confidence contours and prediction contours	UC_ <i>dataName</i> , LC_ <i>dataName</i> , UP_ <i>dataName</i> , LP_ <i>dataName</i>
1	"ErrorBar"	confidence interval wave	CI_ <i>dataName</i>
2	"ErrorBar"	prediction interval wave	PI_ <i>dataName</i>
3	"ErrorBar"	confidence and prediction interval waves	CI_ <i>dataName</i> , PI_ <i>dataName</i>

Note that *confKind* may have 4 added to it if you want coefficient confidence limits calculated as well.

The contour waves are appended to the top graph as traces if the data wave is displayed in the top graph. The wave names have *dataName* replaced with the name of the wave containing the Y data for the fit.

Waves you must supply for `/F={confLevel, confKind, confStyle, wave, wave...}`:

<i>confKind</i>	<i>confStyle</i>	You Supply
1	"Contour"	2 waves to receive upper and lower confidence contours.
2	"Contour"	2 waves to receive upper and lower prediction contours.
3	"Contour"	4 waves to receive upper and lower confidence and upper and lower prediction contours.
1	"ErrorBar"	1 wave to receive values of confidence band width.
2	"ErrorBar"	1 wave to receive values of prediction band width.
3	"ErrorBar"	2 waves to receive values of confidence and prediction band widths.

The waves you supply must have the same number of points as the dependent variable data wave. The band intervals will be calculated at the X values of the input data. These waves are not automatically appended to a graph; it is expected that you will display the contour waves as traces or use the error bar waves to make error bars on the model fit wave.

Residual Details

Residuals are calculated only for elements corresponding to elements of *waveName* that are included in the fit. Thus, you can calculate residuals automatically for a piecewise fit done in several steps.

The automatic residual wave will be appended to the top graph if the graph displays the Y data. It is appended to a new free axis positioned directly above the axis used to display the Y data, making a stacked graph. Other axes are shortened as necessary to make room for the new axis. You can alter the axis formatting later. See **Creating Stacked Plots** on page II-272 for details.

While Igor will go to some lengths to make a nicely formatted stacked graph, the changes made to the graph formatting may be undesirable in certain cases. Use `/A=0` to suppress the automatic append to the graph. The automatic residual wave will be created and filled with residual values, but not appended to the graph.

Inputs and Outputs for Built-In Fits on page III-183 and **Special Variables for Curve Fitting** on page III-199 as well as **Accessing Variables Used by Igor Operations** on page IV-84.

When fitting to a user-specified function, see **FuncFit**. For multivariate user-specified fitting functions, see **FuncFit** and **FuncFitMD**. See **Confidence Bands and Coefficient Confidence Intervals** on page III-191 for a detailed description of confidence and prediction bands.

References

An explanation of the Levenberg-Marquardt nonlinear least squares optimization can be found in Chapter 14.4 of Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

CustomControl

CustomControl [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The CustomControl operation creates or modifies a custom control in the target window. A CustomControl starts out as a generic button, but you can customize both its appearance and its action.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the CustomControl to be created or changed. See **Button** for standard default parameters.

key is one of the following parameters:

<i>mode=m</i>	Notifies the control that something has happened. Can be used for any purpose. See Details discussion of the <code>kCCE_mode</code> event.
<i>noproc</i>	Specifies that no procedure will execute when clicking the custom control.
<i>picture=pict</i>	Uses the named Proc Pictures to draw the control. The picture is taken to be three side-by-side frames, which show the control appearance in the normal state, when the mouse is down, and in the disabled state. The control action function can overwrite the picture number using the <code>picture={pict,n}</code> syntax. The picture size overrides the size keyword.
<i>picture={pict,n}</i>	Uses the specified Proc Picture to draw the control. The picture is <i>n</i> side-by-side frames instead of the default three frames.
<i>pos={left,top}</i>	Sets absolute location in pixels.
<i>proc=procName</i>	Specifies the name of the action function for the control. The function must not kill the control or the window.
<i>size={width,height}</i>	Sets size of the control in pixels but only when not using a Proc Picture.
<i>title=titleStr</i>	Specifies text that appears in the control. <i>titleStr</i> can contain formatting escape codes in order to create fancy, styled results. The escape codes are the same as used by the TextBox operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired, click the To Cmd Line button, and then edit the TextBox command for use with the control.
<i>userdata(UDName)=UDStr</i>	Sets the unnamed user data to <i>UDStr</i> . Use the optional (<i>UDName</i>) to specify a named user data to create.
<i>userdata(UDName)+=UDStr</i>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional (<i>UDName</i>) to append to the named <i>UDStr</i> .
<i>value=varName</i>	Sets the numeric variable, string variable, or wave that is associated with the control. With a wave, specify a point using the standard bracket notation with either a point number (<code>value=awave[4]</code>) or a row label (<code>value=awave[%alabel]</code>).

Flags

/Z No error reporting.

Details

When you create a custom control, your action procedure will need to get information about the state of the control using the `WMCustomControlAction` structure, which is a predefined structure passed to your function. All of the various members of the `WMCustomControlAction` structure are as described in the following tables:

Base WMCustomControlAction Structure Members

Member	Description
char ctrlName[MAX_OBJ_NAME+1]	Control name.
char win[MAX_WIN_PATH+1]	Host (sub)window.
STRUCT Rect winRect	Local coordinates of host window.
STRUCT Rect ctrlRect	Enclosing rectangle of the control.
STRUCT Point mouseLoc	Mouse location.
Int32 eventCode	Event that caused the procedure to execute.
Int32 eventMod	Bitfield of modifiers. See description of MODIFIERS: <i>flags</i> for SetWindow under Unnamed Hooks on page V-505.
String userdata	Primary (unnamed) user data. When this is changed, it is automatically written back.
Int32 missedEvents	TRUE when events occurred but the user function was not available for action.
Int32 mode	General purpose.
Int32 curFrame	Input and output, used with kCCE_frame event.
Int32 needAction	Action meaning depends on the event: Events kCCE_mousemoved, kCCE_enter, and kCCE_leave set to TRUE to force redraw, which is normally not done for these events. Event kCCE_tab and kCCE_mousedown set to TRUE to request keyboard focus (and get kCCE_char events). Event kCCE_idle set to TRUE to request redraw.

Members of WMCustomControlAction Structure with value=varName

Member	Description
Int32 isVariable	TRUE if <i>varName</i> is a numeric variable or a string variable.
Int32 isWave	TRUE if <i>varName</i> referenced a wave.
Int32 isString	TRUE if <i>varName</i> is a String type.
NVAR nVal	If isVariable and not isString.
SVAR sVal	If isVariable and isString.
WAVE nWave	If isWave and not isString.
WAVE/T sWave	If isWave and not isString.
Int32 rowIndex	If isWave, this is the row index unless rowLabel is not null.
char rowLabel[MAX_OBJ_NAME+1]	Wave row label.

Members of **WMCustomControlAction** Structure with **kCCE_char**

Member	Description
Int32 kbChar	Keyboard key character code.
Int32 kbMods	Keyboard key modifiers bit field: bit 0: Command (<i>Macintosh</i>). bit 1: Shift. bit 2: Alpha Lock. bit 3: Option (<i>Macintosh</i>) or Alt (<i>Windows</i>). bit 4: Control.

When determining the state of the `eventCode` member in the `WMCustomControlAction` structure, the various code values you use are defined as in the following table (for each of the `kCCE_` constants that you use you should declare each as `static constant` in your procedures; see **CustomControl** on page III-357 for usage examples):

Event Code	Description
<code>kCCE_mousedown = 1</code>	Mouse down in control.
<code>kCCE_mouseup = 2</code>	Mouse up in control.
<code>kCCE_mouseup_out = 3</code>	Mouse up outside control.
<code>kCCE_mousemoved = 4</code>	Mouse moved (happens only when mouse is over the control).
<code>kCCE_enter = 5</code>	Mouse entered control.
<code>kCCE_leave = 6</code>	Mouse left control.
<code>kCCE_draw = 10</code>	Time to draw custom content.
<code>kCCE_mode = 11</code>	Sent when executing <code>CustomControl name, mode=m</code> .
<code>kCCE_frame = 12</code>	Sent before drawing a subframe of a custom picture.
<code>kCCE_dispose = 13</code>	Sent as the control is killed.
<code>kCCE_modernize = 14</code>	Sent when dependency (variable or wave set by <code>value=varName</code> parameter) fires. It will also get draw events, which probably don't need a response.
<code>kCCE_tab = 15</code>	Sent when user tabs into the control. If you want keystrokes (<code>kCCE_char</code>), then set <code>needAction</code> .
<code>kCCE_char = 16</code>	Sent on keyboard events. Stores the keyboard character in <code>kbChar</code> and modifiers bit field is stored in <code>kbMods</code> . Sets <code>needAction</code> if key event was used and requires a redraw.
<code>kCCE_drawOSBM = 17</code>	Called after drawing <code>pic</code> from picture parameter into an offscreen bitmap. You can draw custom content here.
<code>kCCE_idle = 18</code>	Idle event typically used to blink insertion points etc. Set <code>needAction</code> to force the control to redraw. Sent only when the host window is topmost.

When you call a function with the `kCCE_draw` event, the basic button picture (custom or default) will already have been drawn. You can use standard draw commands such as **DrawLine** to draw on top of the basic picture. Unlike the normal situation when draw commands merely add to a draw list, which only later is drawn, `kCCE_draw` event draw commands are executed directly. The coordinate system, which you can not change, is pixels with (0,0) being the top left corner of the control. Most drawing commands are legal but because of the immediate nature of drawing, the `/A` (append) flag of **DrawPoly** is not allowed.

The `kCCE_mode` event can be used for any purpose, but it mainly serves as a notification to the control that something has happened. For example, to send information to a control, you can set a named (or the unnamed) userdata and then set the `mode` to indicate that the control should examine the userdata. For this signaling purpose, you should use a `mode` value of 0 because this value will not become part of the recreation macro.

The `kCCE_frame` event is sent just before drawing one of the *pic*t frames, as set by the picture parameter. On input, the `curFrame` field is set to 0 (normal or mouse down outside button), to 1 (mouse down in button), or to 2 (disable). You may modify `curFrame` as desired but your value will be clipped to a valid value.

When you specify a *pic*t with the picture parameter, you will get a `kCCE_drawOSBM` event when that *pic*t is drawn into an offscreen bitmap. Once it is created, all updates use the offscreen bitmap until you specify a new picture parameter. Thus the custom drawing done at this event is static, unlike drawing done during the `kCCE_draw` event, which can be different each time the control is drawn. Because the *pic*t can contain multiple side-by-side frames, the width of the offscreen bitmap is the width derived from the `ctrlRect` field multiplied by the number of frames.

Because the action function is called in the middle of various control events, it must not kill the control or the window. Doing so will almost certainly cause a crash.

Examples

See **CustomControl** on page III-357 for some examples of custom controls.

For a demonstration of custom controls, see the Custom Control Demo.pxp example experiment, which is located in your Igor Pro Folder in the Examples:Testing & Misc: folder.

Proc Pictures on page IV-44.

The **TextBox** and **DrawPoly** operations.

CWT

CWT [*flags*] *srcWave*

The CWT operation computes the continuous wavelet transform (CWT) of a 1D real-valued input wave (*srcWave*). The input can be of any numeric type. The computed CWT is stored in the wave `M_CWT` in the current data folder. `M_CWT` is a double precision 2D wave which, depending on your choice of mother wavelet and output format, may also be complex. The dimensionality of `M_CWT` is determined by the specifications of offsets and scales. The operation sets the variable `V_flag` to zero if successful or to a nonzero number if it fails for any reason.

Flags

<code>/ENDM=method</code>	Selects the method used to handle the two ends of the data array with direct integration (<code>/M=1</code>). <code>method=0</code> : Padded on both sides by zeros. <code>method=1</code> : Reflected at both the start and end. <code>method=2</code> : Entered with cyclical repetition.
<code>/FSCL</code>	Use correction factor to the wave scaling of the second dimension of the output wave so that the numbers are more closely related to Fourier wavelength. See References for more information on the calculation of these correction factors. This flag does not affect the output from the Haar wavelet.
<code>/M=method</code>	Specifies the CWT computation method. <code>method=0</code> : Fast method uses FFT (default). <code>method=1</code> : Slower method using direct integration. You should mostly use the more efficient FFT method. The direct method should be reserved to situations where the FFT is not producing optimal results. Theoretically, when the FFT method fails, the direct method should also be fairly inaccurate, e.g., in the case of undersampled signal. The main advantage in the direct method is that you can use it to investigate edge effects.
<code>/OUT=format</code>	Sets the format of the output wave <code>M_CWT</code> : <code>format=1</code> : Complex. <code>format=2</code> : Real valued. <code>format=4</code> : Real and contains the magnitude.

Depending on the method of calculation and the choice of mother wavelet, the “native” output of the transform may be real or complex. You can force the output to have a desired format using this flag.

/Q quiet mode; no results printed to the history.

/R1={startOffset, delta1, numOffsets}

Specifies offsets for the CWT. Offsets are the first dimension in a CWT. Normally you will calculate the CWT for the full range of offsets implied by *srcWave* so you will not need to use this flag. However, when using the slow method, this flag restricts the output range of offsets and save some computation time. *startOffset* (integer) is the point number of the first offset in *srcWave*. *delta1* is the interval between two consecutive CWT offsets. It is expressed in terms of the number *srcWave* points. *numOffsets* is the number of offsets for which the CWT is computed.

By default *startOffset*=0, *delta1*=1, and *numOffsets* is the number of points in *srcWave*. If you want to specify just the *startOffset* and *delta1*, you can set *numOffsets*=0 to use the same number of points as the source wave.

/R2={startScale, scaleStepSize, numScales}

Specifies the range of scales for the CWT is computation. Scales are the second dimension in the output wave. Note however that there are limitations on the minimum and maximum scales having to do with the sampling of your data. Because there is a rough correspondence between a Fourier spatial frequency and CWT scale it should be understood that there is also a maximum theoretical scale. This is obvious if you compute the CWT using an FFT but it also applies to the slow method. If you specify a range outside the allowed limits, the corresponding CWT values are set to NaN.

Use NaN if you want to use the default value for any parameter.

The default value for *startScale* is determined by sampling of the source wave and the wavelet parameter or order.

At a minimum you must specify either *scaleStepSize* or *numScales*.

/SMP1=offsetMode Determines computation of consecutive offsets. Currently supporting only *offsetMode*=1 for linear, user-provided partial offset limits (see /R1 flag):
val1=*startOffset*+*numOffsets***delta1*.

/SMP2=scaleMode Determines computation of consecutive scales. *scaleMode* is 1 by default if you specify the /R2 flag.

scaleMode=1: Linear:

$$theScale = startScale + index * scaleStepSize$$

scaleMode=2: User-provided scaling wave.

scaleMode=4: Power of 2 scaling interval:

$$theScale = startScale * 2.^{(index * scaleStepSize)}$$

When using *scaleMode*=4 the operation saves the consecutive scale values in the wave *W_CWTScaling*. Note also that if you use *scaleMode*=4 without specifying a corresponding /R2 flag, the default *scaleStepSize* of 1 and 64 scale values gives rise to scale values that quickly exceed the allowed limits.

(See /R2 flag for details about the different parameters used in the equations above.)

/SW2=sWave

Provides specific scale values at which the transform is evaluated. Use instead of /R2 flag. It is your responsibility to make sure that the entries in the wave are appropriate for the sampling density of *srcWave*.

/WBI1={Wavelet [, order]}

Specifies the built-in wavelet (mother) function. *Wavelet* is the name of a wavelet function: Morlet (default), MorletC (complex), Haar, MexHat, DOG, and Paul.

Morlet:
$$\Psi_0(x) = \frac{1}{\Pi^{1/4}} \cos(\omega x) e^{-x^2/2}.$$

By default, $\omega=5$. Use the /WPR1 flag to specify other values for ω .

MorletC:
$$\Psi_0(x) = \frac{1}{\Pi^{1/4}} e^{i\omega x} e^{-x^2/2}.$$

By default, $\omega=5$. Use the /WPR1 flag to specify other values for ω .

$$\text{Haar:} \quad \Psi_0(x) = \begin{cases} 1 & 0 \leq x < 0.5 \\ -1 & 0.5 \leq x < 1 \end{cases}.$$

$$\text{DOG:} \quad \Psi_0(m, x) = \frac{(-1)^{m+1}}{\sqrt{\Gamma(m + \frac{1}{2})}} \frac{d^m}{dx^m} (e^{-x^2} \mathbb{P}).$$

MexHat: special case of DOG with $m=2$.

$$\text{Paul:} \quad \Psi_0(m, x) = \frac{2^m i^m m!}{\sqrt{\pi} (2m)!} (1 - ix)^{-(m+1)}.$$

order applies to DOG and Paul wavelets only and specifies m , the particular member of the wavelet family.

The default wavelet is the Morlet.

/WPR1={*param1*} *param1* is a wavelet-specific parameter for the wavelet function selected by /WBI1. For example, use /WPR1={6} to change the Morlet frequency from the default (5).

/Z No error reporting. If an error occurs, sets V_flag to -1 but does not halt function execution.

Details

The CWT can be computed directly from its defining integral or by taking advantage of the fact that the integral represents a convolution which in turn can be calculated efficiently using the fast Fourier transform (FFT).

When using the FFT method one encounters the typical sampling problems and edge effects. Edge effects are also evident when using the slow method but they only significant in high scales.

From sampling considerations it can be shown that the maximum frequency of a discrete input signal is $1/2dt$ where dt is the time interval between two samples. It follows that the smallest CWT scale is $2dt$ and the largest scale is Ndt where N is the total number of samples in the input wave.

The transform in M_CWT is saved with the wave scaling. *startOffset* and *delta1* are used for the X-scaling. Both *startOffset* and *delta1* are either specified by the /R1 flag or copied from *srcWave*. The Y-scaling of M_CWT depends on your choice of /SMP2. If the CWT scaling is linear then the wave scaling is based on *startScale* and *scaleStepSize*. If you are using power of 2 scaling interval then the Y wave scaling of M_CWT has a *start*=0 and *delta*=1 and the wave W_CWTScaling contains the actual scale values for each column of M_CWT. Note that W_CWTScaling has one extra data point to make it suitable for display using an operation like:

AppendImage M_CWT vs {*, W_CWTScaling}

We have encountered two different definitions for the Morlet wavelet in the literature. The first is a complex function (MorletC) and the second is real (Morlet). Instead of choosing one of these definitions we implemented both so you may choose the appropriate wavelet.

See Also

For discrete wavelet transforms use the **DWT** operation. The **WignerTransform** and **FFT** operations.

For further discussion and examples see **Continuous Wavelet Transform** on page III-242.

DataFolderDir

DataFolderDir (*mode*)

The DataFolderDir function returns a string containing a listing of some or all of the objects contained in the current data folder.

Parameters

mode should contain a bitwise flag for each type. Use -1 for all types. Use a sum of the bit values for multiple types.

Desired Type	Bit Number	Bit Value
All		-1
Data folders	0	1
Waves	1	2
Numeric variables	2	4
String variables	3	8

Details

The returned string has the following format:

FOLDERS:*name,name,...*;<CR>

WAVES:*name,name,...*;<CR>

VARIABLES:*name,name,...*;<CR>

STRINGS:*name,name,...*;<CR>

Where <CR> represents the carriage return character.

Tip

This function is mostly useful during debugging, used in a **Print** command. For finding the contents of a data folder programmatically, it will be easier to use the functions **CountObjects** and **GetIndexedObjName**.

Examples

```
Print DataFolderDir(8+4)           // prints variables and strings
Print DataFolderDir(-1)           // prints all objects
```

See Also

Chapter II-8, **Data Folders**.

Setting Bit Parameters on page IV-11 for information about bit settings.

DataFolderExists

DataFolderExists (*folderNameStr*)

The DataFolderExists function returns the truth that the specified data folder exists.

You can use a full or partial path to the data folder.

See Also

Chapter II-8, **Data Folders**.

dateToJulian

dateToJulian (*year, month, day*)

The dateToJulian function returns the Julian day number for the specified date. The Julian day starts at noon. Use negative number for BC years and positive numbers for AD years. To exclude any ambiguity, there is no year zero in this calendar. For general orientation, Julian day 2450000 corresponds to October 9, 1995.

See Also

The **JulianToDate** function.

For more information about the Julian calendar see: <<http://www.tondering.dk/claus/cal/>>.

date

date

date()

The date function returns a string containing the current date.

Formatting of dates depends on your operating system and on your preferences entered in the Date & Time control panel (*Macintosh*) or the Regional Settings control panel (*Windows*).

Examples

```
Print date()           // Prints Mon, Mar 15, 1993
```

See Also

The **Secs2Date**, **Secs2Time**, and **time** functions.

date2secs

date2secs(year, month, day)

The date2secs function returns the number of seconds from midnight on 1/1/1904 to the specified date.

Note that the month and day parameters are one-based, so these series start at one.

If *year*, *month*, and *day* are all -1 then date2secs returns the offset in seconds from the local time to the UTC (Universal Time Coordinate) time.

Examples

```
Print Secs2Date(date2secs(1993,3,15),1)           // Ides of March, 1993
```

Prints the following, depending on your system's date settings, in the history area:

Monday, March 15, 1993

This next example sets the X scaling of a wave to 1 day per point, starting January 1, 1993:

```
Make/N=125 myData = 100 + gnoise(50)
SetScale/P x,date2secs(1993,1,1),24*60*60,"dat",myData
Display myData;ModifyGraph mode=5
```

See Also

The **Secs2Date**, **Secs2Time**, and **time** functions.

DateTime

DateTime

The DateTime function returns number of seconds from 1/1/1904 to current date and time.

Unlike most Igor functions, DateTime is used without parentheses.

Examples

```
Variable now = DateTime
```

See Also

The **Secs2Date**, **Secs2Time** and **time** functions.

dawson

dawson(x)

The dawson function returns the value of the Dawson integral:

$$F(x) = \exp(-x^2) \int_0^x \exp(t^2) dt.$$

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

DDEExecute

DDEExecute(refNum, cmdStr [, timeout])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEExecute function sends a string of commands, *cmdStr*, to the server for execution. The format of the commands depends on the server application.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEExecute returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

In some situations, you may want to use a zero *timeout* and then use DDEStatus to monitor when the server is finished. You would do this if the server might take a long time to accomplish the commands and you want Igor to continue working at the same time.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEInitiate

DDEInitiate(serverName, topicName)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEInitiate function opens a DDE session and returns a reference number for use by the rest of the DDE routines. Returns zero if failure.

If the desired application is not running, DDEInitiate will return zero. If this occurs, you can use the ExecuteScriptText operation to start the server application.

Refer to your application's documentation for the *serverName* and *topicName*. See the following example for usage with Excel.

Examples

```
Variable ch= DDEInitiate("excel","book1")
```

See Also

The **ExecuteScriptText** operation. For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEPokeString

DDEPokeString(refNum, itemString, string [, timeout])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEPokeString function sends *string* to the server.

itemString is a string specifying the server application's DDE item name for the location into which to store the string. For example, "R1C1" specifies the first cell in an Excel spreadsheet.

refNum is the DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEPokeString returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEPokeWave

DDEPokeWave(refNum, itemString, wave [, timeout [, format]])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEPokeWave function sends data from a *wave* to the server.

itemString is a string specifying the server application's DDE item name for the location into which to store the string. For example, "R1C1:R10C10" specifies a 10x10 block of cells in an Excel spreadsheet.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDEPokeWave returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the *timeout* period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *format* parameter can be 0 to send the data as tab-delimited text (default) or can be 1 to specify Microsoft's XLTable (excel) format. To specify *format* without specifying *timeout*, the latter may be completely missing (, ,) or a * symbol may be used:

```
err= DDEPokeWave(ch,"R1C1:R10C10",*,1)
```

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

Examples

A session using Microsoft Excel:

```
Variable ch,err1,err2
ch= DDEInitiate("excel","book1")
Make/O/N=(5,5) jack= P+10*Q
err1= DDEPokeWave(ch,"R1C1:R5C5",jack)
err2= DDETerminate(ch)
```

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDERequestString

DDERequestString(refNum, itemString [, timeout])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDERequestString string function returns a string of requested data or null handle in case of failure.

itemString is a string specifying the server application's DDE item name for the data being requested. For example, "R1C1" specifies the first cell in an Excel spreadsheet.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDERequestWave

DDERequestWave(refNum, itemString, destWave [, timeout])

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDERequestWave function loads a preexisting wave with data from the server. The provided destination wave, *destWave*, can be either text or numeric. Data from the server must be a tab delimited array. It is analyzed to determine the dimensions of the wave but the numeric type (or string type) of the wave is not changed.

itemString is a string specifying the server application's DDE item name for the requested data. For example, "R1C1:R10C10" specifies a 10x10 block of cells in an Excel spreadsheet.

refNum is a DDE session reference number returned by DDEInitiate to start a particular session.

It returns an error code from the server or zero if there was no error.

DDERequestWave returns -1 if the server gave an error but the error code was zero. Returns -2 if the server did not reply before the timeout period. Returns -3 if the *refNum* is invalid and -4 for other errors.

The optional *timeout* value is in seconds. The default *timeout* is 60 sec.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDEStatus

DDEStatus (refNum)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDEStatus function returns the status of the DDE session defined by *refNum* from a previous DDEInitiate.

Returns zero if *refNum* is not valid or if the session has been closed.

Returns nonzero if session is valid where the individual bits have the following meanings:

Bit 0: Set if the session is valid and not busy.

Bit 1: Set if waiting for an ack from the server for a previous DDEPoke or DDEExecute that timed out. (bit 0 and 1 are exclusive).

Bit 2: Set if the ack from the server for a previous poke or execute command was negative. Only applies to timed out commands.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

DDETerminate

DDETerminate (refNum)

This is a *Windows-only* function; it will return an error on the Macintosh.

The DDETerminate function closes the DDE session defined by *refNum* from a previous DDEInitiate. Returns truth session was valid.

Pass zero to terminate all client sessions.

See Also

For further information refer to the other DDE functions and to the DDE Server and DDE Client sections in the Obsolete Topics help file.

Debugger

Debugger

The Debugger operation breaks into the debugger if it is enabled.

See Also

The **Debugger** on page IV-154 and the **DebuggerOptions** operation.

DebuggerOptions

DebuggerOptions [**enable=en**, **debugOnError=doe**, **NVAR_SVAR_WAVE_Checking=nvwc**]

The DebuggerOptions operation programmatically changes the user-level debugger settings. These are the same three settings that are available in the Procedure menu (and the debugger source pane contextual menu)

Parameters

All parameters are optional. If none are specified, no action is taken, but the output variables are still set.

enable=en Turns the debugger on (*en*=1) or off (*en*=0).

If the debugger is disabled then the other settings are cleared even if other settings are on.

debugOnError=doe Turns Debugging On Error on or off.

default

doe=0: Disables Debugging On Error (see **Debugging on Error** on page IV-155).

doe=1: Enables Debugging On Error and also enables the debugger (implies *enable=1*).

NVAR_SVAR_WAVE_Checking=*nvwc*

Turns NVAR, SVAR, and WAVE checking on or off.

nvwc=0: Disables “NVAR SVAR WAVE Checking”. See **Runtime Lookup of Globals** on page IV-50 for more details.

nvwc=1: Enables this checking and also enables the debugger (implies *enable=1*).

Details

DebuggerOptions sets the following variables to indicate the Debugger settings that are in effect *after* the command is executed. A value of zero means the setting is off, nonzero means the setting is on.

V_enable	V_debugOnError	V_NVAR_SVAR_WAVE_Checking
----------	----------------	---------------------------

See Also

The **Debugger** on page IV-154 and the **Debugger** operation.

default

default:

The default flow control keyword is used in switch and strswitch statements. When none of the case labels in the switch or strswitch match the evaluation expression, execution will continue with code following the default label, if it is present.

See Also

Switch Statements on page IV-33.

DefaultFont

DefaultFont [/U] "*fontName*"

The DefaultFont operation sets the default font to be used in graphs for axis labels, tick mark labels and annotation, and in page layouts for annotations.

Parameters

"*fontName*" should be a font name, optionally in quotes. The quotes are not required if the font name is one word.

Flags

/U	Updates existing graphs and page layouts immediately to use the new default font.
----	---

DefaultGuiControls

DefaultGuiControls [/Mac/W=*winName*/Win] [*appearance*]

The DefaultGuiControls operation changes the appearance of user-defined controls.

Note: The recommended way to change the appearance of user-defined controls is to use the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab, which is equivalent to DefaultGuiControls native when checked, and to DefaultGuiControls os9 when unchecked.

Use DefaultGuiControls/W=*winName* to override that setting for individual windows.

Parameters

appearance may be one of the following:

native	Creates standard-looking controls for the current computer platform.
os9	Igor Pro 5 appearance (quasi-Macintosh OS 9 controls that look the same on Macintosh and Windows). This is the default for backwards compatibility with experiments created before version 6.02.
default	Inherits the window appearance from either a parent window or the experiment-wide default (only valid with /W).

Flags

/Mac	Changes the appearance of controls only on Macintosh, and it affects the experiment whenever it is used on Macintosh.
/W= <i>winName</i>	Affects the named window or subwindow. When omitted, sets an experiment-wide default. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Win	Changes the appearance of controls only on Windows, and it affects the experiment whenever it is used on Windows.

Details

If *appearance* is not specified, nothing is changed. The current value for appearance is returned in *S_value*.

If *appearance* is specified the previous appearance value for the window- or experiment-wide default is returned in *S_value*.

With /W, the control appearance applies only to the specified window (Graph or Panel). If it is not used, then the settings are global to experiments on the current computer. **Tip:** Use /W=# to refer to the current active subwindow.

The /Mac and /Win flags specify the affected computer platform. If the current platform other than specified, then the settings are not used, but (if native or OS9) are remembered for use in window recreation macros or experiment recreation. This means you can create an experiment that with different appearances depending on the current platform.

If neither /Mac nor /Win are used, it is implied by the current platform. To set native appearance on both platforms, use two commands:

```
DefaultGuiControls/W=Panel0/Mac native
```

```
DefaultGuiControls/W=Panel0/Win native
```

Note: The setting for DefaultGuiControls without /W is not stored in the experiment file; it is a user preference set by the Miscellaneous Settings dialog's Native GUI Appearance for Controls checkbox in the Compatibility tab. If you use DefaultGuiControls native or DefaultGuiControls os9 commands, the checkbox will not show the current state of the experiment-wide setting. Clicking Save Settings in the Miscellaneous Settings dialog will overwrite the DefaultGuiControls setting (but not the per-window settings).

In addition to the experiment-wide appearance setting and the window-specific appearance setting, an individual control's appearance can be set with the appropriate control command's appearance keyword (or a ModifyControl appearance keyword). A control-specific appearance setting overrides a window-specific appearance, which in turn overrides the experiment-wide appearance setting.

Although meant to be used before controls are created, calling DefaultGuiControls will update all open windows.

DefaultGuiControls does not change control fonts or font sizes, which means you can create controls that look "native-ish" without having to readjust their positions to avoid overlap.

To better approximate truly native control appearance, use DefaultGuiFont all={"_NativeSizes",0,0} or the Miscellaneous Settings Dialog's Native GUI Font Sizes for Controls checkbox in the Compatibility tab. You will probably need to adjust the positions of the affected controls to prevent overlap or to maintain alignments. This command is stored in the experiment file, and is not backwards compatible with versions before 6.02.

The native appearance affects the way that controls are drawn in **TabControl** and **GroupBox** controls.

TabControl Background Details

Unlike the os9 appearance which draws only an outline to define the tab region (leaving the center alone) the native tab appearance fills the tab region. Fortunately, TabControls are drawn before all other kinds of controls which allows enclosed controls to be drawn on top of a tab control regardless of the order in which the buttons are defined in the window recreation macro.

However the drawing order of native TabControls does matter: the top-most TabControls draws over other TabControls. (The top-most TabControl is listed last in the window recreation macro.) The os9 appearance allows a smaller (nested) TabControl to be underneath the later (enclosing) TabControl because tabs normally aren't filled. Converting these tabs to native appearance will cause nested tab to be hidden.

To fix the drawing order problem in an existing panel, turn on the drawing tools, select the arrow tool, right-click the enclosing TabControl, and choose Send to Back to correct this situation. If the TabControl itself is inside another TabControl, select that enclosing TabControl and also choose Send to Back, etc.

To fix the window recreation macro or function that created the panel, arrange the enclosing TabControl commands to execute before the commands that create the enclosed TabControls.

A natively-drawn TabControl draws any drawing objects inside the tab region so that it behaves the same as an os9 unfilled TabControl with drawing objects inside.

GroupBox Control Background Details

GroupBox controls, unlike TabControls, are not drawn before all other controls, so the drawing order always matters if the GroupBox specifies a background (fill) color and it contains other controls.

You may find that enabling native appearance hides some controls inside the GroupBox. They are probably underneath (before) the GroupBox in the drawing order.

To fix this in an existing panel, turn on the drawing tools, right-click on the GroupBox and choose Send to Back. To fix the window recreation macro or function that created the panel, arrange the GroupBox commands to execute before the commands that create the enclosed controls.

A natively-drawn GroupBox draws any drawing objects inside of the box; an os9 filled GroupBox does not.

See Also

The **DefaultGuiFont**, **ModifyControl**, **Button**, **GroupBox**, and **TabControl** operations.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

DefaultGuiFont

DefaultGuiFont [/W=*winName* /Mac/Win] **group** = {*fNameStr*,*fSize*,*fStyle*} [,...]

The DefaultGuiFont operation changes the default font for user-defined controls and other Graphical User Interface elements.

Parameters

fNameStr is the name of a font, *fSize* is the font size, and *fStyle* is a binary coded number with each bit controlling one aspect of the font style. See **Button** for details about these parameters.

group may be one of the following:

all	All controls
button	Button and default CustomControl
checkbox	CheckBox controls
tabcontrol	TabControl controls
popup	Affects the icon (not the title) of a PopupMenu control. The text in the popped state is set by the system and can not be changed. The title of a PopupMenu is affected by the all group but the icon text is not.
panel	Draw text in a panel.
graph	Overlay graphs. Size is used only if <code>ModifyGraph gfSize= -1</code> ; style is not used.
table	Overlay tables.

Flags

/Mac	Changes control fonts only on Macintosh, and it affects the experiment whenever it is used on Macintosh.
/W= <i>winName</i>	Affects the named window or subwindow. When omitted, sets an experiment-wide default. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Win	Changes control fonts only on Windows, and it affects the experiment whenever it is used on Windows.

Details

Although designed to be used before controls are created, calling DefaultGuiFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

The /Mac and /Win flags indicate the platform on which the fonts are to be used. If the current platform is not the one specified then the settings are not used but are remembered for use in window recreation macros or experiment recreation. This allows a user to create an experiment that will use different fonts depending on the current platform.

If the /W flag is used then the font settings apply only to the specified window (Graph or Panel.) If the /W flag is not used, then the settings are global to the experiment. Tip: Use /w=# to refer to the current active subwindow.

fNameStr may be a null string, "", to clear a group. Setting the font name to "_IgorSmall", "_IgorMedium", or "_IgorLarge" will use Igor's own defaults. The standard defaults for controls are the equivalent to setting all to "_IgorSmall", tabcontrol to "_IgorMedium", and button to "_IgorLarge". Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

Although designed to be used before controls are created, calling DefaultGuiFont will update all affected windows with controls. This makes it easy to experiment with fonts. Keep in mind that fonts can cause compatibility problems when moving between machines or platforms.

To read back settings, use DefaultGuiFont [/W=winName/Mac/Win/OVR] *group* to return the current font name in S_name, the size in V_value, and the style in V_flag. With /OVR or if /Mac or /Win is not current, it returns only override values. Otherwise, values include Igor built-in defaults. If S_name is zero length, values are not defined.

Default Fonts and Sizes

The standard defaults for controls is the equivalent to setting all to "_IgorSmall", tabcontrol to "_IgorMedium", and button to "_IgorLarge". Use a *fSize* of zero to also get the standard default for size. On Windows, the three default fonts and sizes are all the same.

Control	Macintosh		Windows	
	Font	Font Size	Font	Font Size
Button	Lucida Grande	13	MS Shell Dlg*	12
Checkbox	Geneva	9	MS Shell Dlg	12
GroupBox	Geneva	9	MS Shell Dlg	12
ListBox	Geneva	9	MS Shell Dlg	12
PopupMenu [†]	Geneva	9	MS Shell Dlg	12
SetVariable	Geneva	9	MS Shell Dlg	12
Slider	Geneva	9	MS Shell Dlg	12
TabControl	Geneva	12	MS Shell Dlg	12
TitleBox	Geneva	9	MS Shell Dlg	12
ValDisplay	Geneva	9	MS Shell Dlg	12

* MS Shell Dlg is a "virtual font name", which usually maps to Tahoma on Windows 2000 and XP.

† PopupMenu font for the title is Geneva 9 on Macintosh, for the popup menu itself the font is Lucida Grande 12. On Windows, both fonts are MS Shell Dlg 12.

Examples

```
DefaultGuiFont/Mac all={"Zapf Chancery",12,0},panel={"geneva",12,3}
DefaultGuiFont/Win all={"Century Gothic",12,0},panel={"arial",12,3}
NewPanel
Button b0
DrawText 40,43,"Some text"
```

The **DefaultGuiControls** operation. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

The example experiment: All Controls Demo.pxp.

DefineGuide

DefineGuide [*/W= winName*] **newGuideName** = {[*guideName1*, val [*,* *guideName2*]]} [*,*...]

The DefineGuide operation creates or overwrites a user-defined guide line in the target or named window or subwindow. Guide lines help with the positioning of subwindows in a host window.

Parameters

newGuideName is the name for the newly created guide. When it is the name of an existing guide, the guide will be moved to the new position.

guideName1, *guideName2*, etc., must be the names of existing guides.

The meaning of *val* depends on the form of the command syntax. When using only one guide name, *val* is an absolute distance offset from to the guide. The directionality of *val* is to the right or below the guide for positive values. The units of measure are points except in panels where they are in pixels. When using two guide names, *val* is the fractional distance between the two guides.

Flags

/W=winName Defines guides in the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The names for the built-in guides are as defined in the following table:

	Left	Right	Top	Bottom
Host Window Frame	FL	FR	FT	FB
Host Graph Rectangle	GL	GR	GT	GB
Inner Graph Plot Rectangle	PL	PR	PT	PB

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

To delete a guide use *guideName*={}.

See Also

Display, **Edit**, **GuideInfo**, **NewPanel**, **NewImage**, and **NewWaterfall** operations.

DelayUpdate

DelayUpdate

The DelayUpdate operation delays the updating of graphs and tables while executing a macro.

Details

Use DelayUpdate at the end of a line in a macro if you want the next line in the macro to run before graphs or tables are updated.

This has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the **DoUpdate** operation.

See Also

The **DoUpdate**, **PauseUpdate**, and **ResumeUpdate** operations.

DeleteFile

DeleteFile [*flags*] [*fileNameStr*]

The DeleteFile operation deletes a file on disk.

Parameters

fileNameStr can be a full path to the file to be deleted (in which case */P* is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not locate the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be deleted.

If you use a full or partial path for either file, see **Path Separators** on page III-382 for details on forming the path.

Flags

/I	Interactive mode displays the Open File dialog even if <i>fileNameStr</i> is specified and the file exists.
/M= <i>messageStr</i>	Specifies the prompt message for the Open File dialog.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/Z[= <i>z</i>]	Prevents procedure execution from aborting if it attempts to delete a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort. /Z=0: Same as no /Z. /Z=1: Deletes a file only if it exists. /Z alone has the same effect as /Z=1. /Z=2: Deletes a file if it exists or displays a dialog if it does not exist.

Variables

The DeleteFile operation returns information in the following variables:

V_flag	Set to zero if the file was deleted, to -1 if the user cancelled the Open File dialog, and to some nonzero value if an error occurred, such as the specified file does not exist.
S_path	Stores the full path to the file that was deleted. If an error occurred or if the user cancelled, it is set to an empty string.

See Also

DeleteFolder, **MoveFile**, **CopyFile**, **NewPath**, and **Symbolic Paths** on page II-30.

DeleteFolder

DeleteFolder [*flags*] [*folderNameStr*]

The DeleteFolder operation deletes a disk folder and all of its contents.

Warning: *The DeleteFolder command destroys data!* The deleted folder and the contents are not moved to the Trash or Recycle Bin.

DeleteFolder will delete a folder only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog's Misc category. For further details see **Misc Settings** on page III-398.

If permission is denied, the folder will not be deleted and V_Flag will return 1088 (Command is disabled) or 1276 (You denied permission to delete a folder). Command execution will cease unless the /Z flag is specified.

Parameters

folderNameStr can be a full path to the folder to be deleted, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a folder within the folder associated with *pathName*.

If Igor can not determine the location of the folder from *folderNameStr* and *pathName*, it displays a Select Folder dialog allowing you to specify the folder to be deleted.

If /P=*pathName* is given, but *folderNameStr* is not, then the folder associated with *pathName* is deleted.

If you use a full or partial path for either folder, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

Flags

/I	Interactive mode displays a Select Folder dialog even if <i>folderNameStr</i> is specified and the folder exists.
/M= <i>messageStr</i>	Specifies the prompt message for the Select Folder dialog.
/P= <i>pathName</i>	Specifies the folder to look in for the folder. <i>pathName</i> is the name of an existing symbolic path.

DeletePoints

`/Z[=z]` Prevents procedure execution from aborting if it attempts to delete a folder that does not exist. Use `/Z` if you want to handle this case in your procedures rather than having execution abort.

`/Z=0:` Same as no `/Z`.

`/Z=1:` Deletes a folder only if it exists. `/Z` alone has the same effect as `/Z=1`.

`/Z=2:` Deletes a folder if it exists or displays a dialog if it does not exist.

Variables

The DeleteFolder operation returns information in the following variables:

`V_flag` Set to zero if the folder was deleted, to -1 if the user cancelled the Select Folder dialog, and to some nonzero value if an error occurred, such as the specified folder does not exist.

`S_path` Stores the full path to the folder that was deleted, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only `/P=pathName` (without `folderNameStr`) to specify the source folder to be deleted.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

See Also

The **DeleteFile**, **MoveFolder**, **CopyFolder**, **NewPath**, and **IndexedDir** operations. **Symbolic Paths** on page II-30.

DeletePoints

DeletePoints [`/M=dim`] *startElement*, *numElements*, *waveName*
[, *waveName*]...

The DeletePoints operation deletes *numElements* elements from the named waves starting from element *startElement*.

Flags

`/M=dim` *dim* specifies the dimension from which elements are to be deleted. Values are:

- 0: Rows.
- 1: Columns.
- 2: Layers.
- 3: Chunks.

If `/M` is omitted, DeletePoints deletes from the rows dimension.

Details

Removing all but one element from the highest dimension of a wave reduces the dimensionality of the wave by one.

A wave may have any number of points, including zero. Removing all elements from any dimension removes all points from the wave, leaving a 1D wave with zero points.

See Also

The **Redimension** operation.

deltax

deltax(*waveName*)

The deltax function returns the named wave's Δx value. deltax works with 1D waves only.

Details

This is equal to the difference of the X value of point 1 minus the X value of point 0.

See Also

The **leftx** and **rightx** functions.

When working with multidimensional waves, use the **DimDelta** function.

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-70.

Differentiate

```
Differentiate [type flags][flags] yWaveA [/X = xWaveA]
               [/D = destWaveA][, yWaveB [/X = xWaveB]/D = destWaveB][, ...]
```

The Differentiate operation calculates the numerical derivative of a wave.

Flags

/DIM= <i>d</i>	Specifies the wave dimension to differentiate. <i>d</i> =-1: Treats entire wave as 1D (default). For <i>d</i> =0, 1, ..., operates along rows, columns, etc.
/EP= <i>e</i>	Controls end point handling. <i>e</i> =0: Replaces undefined points with an approximation (default). <i>e</i> =1: Deletes the point(s).
/METH= <i>m</i>	Sets the differentiation method. <i>m</i> =0: Central difference (default). <i>m</i> =1: Forward difference. <i>m</i> =2: Backward difference.
/P	Forces point scaling.

Type Flags (used only in functions)

Differentiate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Wave Parameters

Note: All wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name.

/D= <i>destWave</i>	Specifies the name of the wave to hold the differentiated data. It creates <i>destWave</i> if it does not already exist or overwrites it if it exists.
/X= <i>xWave</i>	Specifies the name of the corresponding X wave.

Details

If the optional /D = *destWave* flag is omitted, then the wave is differentiated in place overwriting the original data.

When using a method that deletes points (/EP=1) with a multidimensional wave, deletion is not done if no dimension is specified.

When using an X wave, the X wave must match the Y wave data type (excluding the complex type flag) and it must be 1D with the number points matching the size of the dimension being differentiated. X waves are not used with integer source waves.

Unsigned integer waves are treated as if they were signed.

Differentiate/METH=1/EP=1 is the inverse of Integrate/METH=2, but Integrate/METH=2 is the inverse of Differentiate/METH=1/EP=1 only if the original first data point is added to the output wave.

Differentiate applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see **Sort**).

See Also

The **Integrate** operation.

digamma

digamma(*x*)

The digamma function returns the digamma, or psi function of *x*. This is the logarithmic derivative of the gamma function:

DimDelta

$$\psi(z) \equiv \frac{d}{dz} \ln \Gamma(z) = \frac{\Gamma'(z)}{\Gamma(z)}.$$

In complex expressions, x is complex, and `digamma(x)` returns a complex value.

Limited testing indicates that the accuracy is approximately 1 part in 10^{16} , at least for moderately-sized values of x .

DimDelta

DimDelta(waveName, dimNumber)

The DimDelta function returns the scale factor delta of the given dimension.

Use `dimNumber=0` for rows, 1 for columns, 2 for layers and 3 for chunks. If `dimNumber=0` this is identical to `delta(x(waveName))`.

See Also

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-70.

DimOffset

DimOffset(waveName, dimNumber)

The DimOffset function returns the scaling offset of the given dimension.

Use `dimNumber=0` for rows, 1 for columns, 2 for layers, and 3 for chunks. If `dimNumber=0` this is identical to `leftx(waveName)`.

See Also

For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-70.

DimSize

DimSize(waveName, dimNumber)

The DimSize function returns the size of the given dimension.

Use `dimNumber=0` for rows, 1 for columns, 2 for layers, and 3 for chunks. For a 1D wave, `DimSize(waveName, 0)` is identical to `numpts(waveName)`.

Dir

Dir [dataFolderSpec]

The Dir operation returns a listing of all the objects in the specified data folder.

Parameters

If you omit `dataFolderSpec` then the current data folder is used.

If present, `dataFolderSpec` can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

The format of the printed information is the same as the format used by the string function **DataFolderDir**. Igor programmers may find it more convenient to use **CountObjects** and **GetIndexedObjName**.

Usually it is easier to use the Data Browser (Data menu). However, **Dir** is useful when you want to copy a name into the command line or when you want to document the current state of the folder in the history.

See Also

Chapter II-8, **Data Folders**.

Display

Display [*flags*] [*waveName* [, *waveName*]...[*vs xwaveName*]]
[*as titleStr*]

The Display operation creates a new graph window or subwindow, and appends the named waves, if any. Waves are displayed as 1D traces.

By default, waves are plotted versus the left and bottom axes. Use the /L, /B, /R, and /T flags to plot the waves against other axes.

Parameters

Up to 100 *waveNames* may be specified, subject to the 400 character command limit. If no wave names are specified, a blank graph is created and the axis flags are ignored.

If you specify "*vs xwaveName*", the Y values of the named waves are plotted versus the Y values of *xwaveName*. If you don't specify "*vs xwaveName*", the Y values of each *waveName* are plotted versus its own X values.

If *xwaveName* is a text wave, the resulting plot is a category plot. Each element of *waveName* is plotted by default in bars mode (**ModifyGraph** mode=5) against a category labeled with the text of the corresponding element of *xwaveName*.

The Y waves for a category plot should have point scaling (see **Changing Dimension and Data Scaling** on page II-70); this is how category plots were intended to work. However, if all the Y waves have the same scaling, it will work correctly.

titleStr is a string expression containing the graph's title. If not specified, Igor will provide one which identifies the waves displayed in the graph.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-267.

Flags

/B[= <i>axisName</i>]	Plots X coordinates versus the standard or named bottom axis.
/FG=(<i>gLeft</i> , <i>gTop</i> , <i>gRight</i> , <i>gBottom</i>)	Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window. The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name. Guides may override the numeric positioning set by /W.
/HIDE= <i>h</i>	Creates a hidden graph window or subwindow with <i>h</i> =1. Graph is visible with <i>h</i> =0. Use SetWindow to change visibility.
/HOST= <i>hcSpec</i>	Embeds the new graph in the specified host window or subwindow <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/I	Specifies that /W coordinates are in inches.
/K= <i>k</i>	Specifies window behavior when closed. <i>k</i> =0: Normal with dialog (default) <i>k</i> =1: Kills with no dialog <i>k</i> =2: Disables killing
/L[= <i>axisName</i>]	Plots Y coordinates versus the standard or named left axis.
/M	Specifies that /W coordinates are in centimeters.
/N= <i>name</i>	Requests that the created graph have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name. Use DoWindow/K name to ensure that <i>name</i> is available.
/PG=(<i>gLeft</i> , <i>gTop</i> , <i>gRight</i> , <i>gBottom</i>)	Specifies the inner plot rectangle of the graph subwindow inside its host window. The standard plot rectangle guide names are PL, PR, PT, and PB, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.

	Guides may override the numeric positioning set by /W.
/R[= <i>axisName</i>]	Plots Y coordinates versus the standard or named right axis.
/T[= <i>axisName</i>]	Plots Y coordinates versus the standard or named top axis.
/W=(<i>left,top,right,bottom</i>)	Gives the graph a specific location and size on the screen. Coordinates for /W are in points unless /I or /M are specified before /W. When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings: <ol style="list-style-type: none">1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.2) When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame. When the subwindow position is fully specified using guides (using the /HOST, /FG, or /PG flags), the /W flag may still be used although it is not needed.

Details

If /N is not used, Display automatically assigns to the graph a name of the form “Graph n ”, where n is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the graph from a procedure. Use the **RenameWindow** operation to rename the graph.

Examples

To make a contour plot, use:

```
Display; AppendMatrixContour waveName
```

or

```
Display; AppendXYZContour waveName
```

To display an image, use:

```
Display; AppendImage waveName
```

or

```
NewImage waveName
```

See Also

The operations **AppendImage**, **AppendMatrixContour**, **AppendXYZContour**, and **NewImage**. For more information on Category Plots, see Chapter II-13, **Category Plots**.

The operations **ModifyGraph**, **ModifyContour**, and **ModifyImage** for changing the characteristics of graphs.

The **DoWindow** operation for changing aspects of the graph window.

DisplayHelpTopic

DisplayHelpTopic [/K= k /Z] *TopicString*

The DisplayHelpTopic operation displays a help topic as if a help link had been clicked in an Igor help file.

Parameters

TopicString is string expression containing the topic. It may be in one of three forms: <topic name>, <subtopic name>, <topic name>[<subtopic name>]. These forms are illustrated by the examples.

Make sure that your topic string is specific to minimize the likelihood that Igor will find the topic in a help file other than the one you intended. To avoid this problem, it is best to use the <topic name>[<subtopic name>] form if possible.

Flags

/K= k	$k=0$:	Leaves the help file open indefinitely (default). Use this if the help topic may be of interest in any experiment.
	$k=1$:	If the found topic is in a closed help file, the help file closes with the current experiment. Use this if the help topic is tightly associated with the current experiment.
/Z		Ignore errors. If /Z is used, DisplayHelpTopic sets V_Flag to 0 if the help topic was found or to a nonzero error code if it was not found. V_flag is set only when /Z is used.

Details

DisplayHelpTopic first searches for the specified topic in the open help files. If the topic is not found, it then searches all help files in the Igor Pro folder and subfolders.

If the topic is still not found, it then searches all help files in the current experiment's home folder, but not in subfolders. This puts a help file that is specific to a particular experiment in the experiment's home folder.

If the topic is still not found and if DisplayHelpTopic was called from a procedure and if the procedure resides in a stand-alone file on disk (i.e., it is not in the built-in procedure window or in a packed procedure file), Igor then searches all help files in the procedure file's folder, but not in subfolders. This puts a help file that is specific to a particular set of procedures in the same folder as the procedure file.

If Igor finds the topic, it displays it. If Igor can not find the topic, it displays an error message, unless /Z is used.

Examples

```
// This example uses the topic only.
DisplayHelpTopic "Waves"

// This example uses the subtopic only.
DisplayHelpTopic "Waveform Arithmetic and Assignment"

// This example uses the topic[subtopic] form.
DisplayHelpTopic "Waves[Waveform Arithmetic and Assignment]"
```

DisplayProcedure

DisplayProcedure [**/B=winTitleOrName** **/W=procWinTitle**] [**functionOrMacroNameStr**]

The DisplayProcedure operation displays the named function or macro by bringing the procedure window it is defined in to the front with the function or macro highlighted.

Parameters

functionOrMacroNameStr is string expression containing the function or macro name. If omitted, you must use /W.

Flags

<i>/B=winTitleOrName</i>	Brings up the procedure window just behind the window with this name or title.
<i>/W=procWinTitle</i>	Searches in the procedure window with this title. If omitted, it searches all open (nonindependent module) procedure windows.

Details

If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then DisplayProcedure may not be able to locate the procedure.

winTitleOrName is not a string; it is a name. To position the found procedure window behind a window whose title has a space in the name, use the \$ operator as in the second example, below.

If *winTitleOrName* does not match any window, then the found procedure window is placed behind the top target window.

procWinTitle is also a name. Use */W="\$ "New Polar Graph.ipf"* to search for the function or macro in only that procedure file.

Advanced Details

If SetIgorOption IndependentModuleDev=1, *procWinTitle* can also be a title followed by a space and, in brackets, an independent module name. In such cases searches for the function or macro are in the specified procedure window and independent module. (See **The IndependentModule Pragma** on page IV-40 for independent module details.)

For example, if any procedure file contains these statements:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

The command

```
DisplayProcedure/W="$ "Axis Utilities.ipf [myIM]" "HVAxisList"
```

do-while

opens the procedure window that contains the `HVAxisList` function, which is in the `Axis Utilities.ipf` file and the independent module `myIM`. The command uses the `$""` syntax because space and bracket characters interfere with command parsing.

`procWinTitle` can also be just an independent module name in brackets to retrieve the text from *any* procedure window that belongs to named independent module:

```
DisplayProcedure/W=$[myIM] "HVAxisList"
```

Examples

```
DisplayProcedure "Graph0"
DisplayProcedure/B=$"Strings as Lists.ipf" "MyOwnUserFunction"
DisplayProcedure/W=Procedure // Shows the main Procedure window
DisplayProcedure/W=$"Strings as Lists.ipf"
```

See Also

The **IndependentModule Pragma** on page IV-40. The **MacroList**, **FunctionList**, and **ProcedureText** Functions; the **HideProcedures** and **DoWindow** operations.

do-while

do

<loop body>

while(*<expression>*)

A do-while loop executes *loop body* until *expression* evaluates as FALSE (zero) or until a break statement is executed.

See Also

Do-While Loop on page IV-34 and **break** for more usage details.

DoAlert

DoAlert *alertType*, *promptStr*

The `DoAlert` operation puts up an alert dialog and waits for user to click button.

Parameters

alertType= 0: Dialog with an OK button.
1: Dialog with Yes button and No buttons.
2: Dialog with Yes, No, and Cancel buttons.

promptStr text that is displayed in the alert dialog.

Details

`DoAlert` sets the variable `V_flag` as follows:

`V_flag`= 1: Yes clicked.
2: No clicked.
3: Cancel clicked.

See Also

The **Abort** operation.

DoIgorMenu

DoIgorMenu [/C] *MenuNameStr*, *MenuItemStr*

The `DoIgorMenu` operation allows an Igor programmer to invoke Igor's built-in menu items. This is useful for bringing up Igor's built-in dialogs under program control.

Parameters

MenuNameStr The name of an Igor menu, like "File", "Graph", or "Load Waves".
MenuItemStr The text of an Igor menu item, like "Copy" (in the Edit menu) or "New Graph" (in the Windows menu).

Flags

/C Just Checking. The menu item is not invoked, but V_flag is set to 1 if the item was enabled or to 0 if it was not enabled.

Details

All menu names and menu item text are in English to ensure that code developed for a localized version of Igor Pro will run on all versions. Note that no trailing “...” is used in *MenuItemStr*.

V_flag is set to 1 if the corresponding menu item was enabled, which usually means the menu item was successfully selected. Otherwise V_flag is 0. V_flag does not reflect the success or failure of the resulting dialog, if any.

If the menu item selection displays a dialog that generates a command, clicking the Do It button executes the command immediately without using the command line as if Execute/Z operation had been used. Clicking the To Cmd Line button appends the command to the command line rather than inserting the command at the front.

The DoIgorMenu operation will not attempt to select a menu during curve fitting. Doubtless there are other times during which using DoIgorMenu would be unwise.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use “Save Window”, “Save Window As”, “Save Window Copy”, “Adopt Window”, and “Revert Window” instead of “Save Notebook” or “Save Procedure”, etc. Use “Page Setup” instead of “Page Setup For All Graphs”, etc. Use “Print” instead of “Print Graph”, etc.

See Also

The **SetIgorMenuMode** and **Execute** operations.

DoPrompt

DoPrompt [/HELP=*helpStr*] *dialogTitleStr*, *variable* [, *variable*]...

The DoPrompt command in a function invokes the simple input dialog. A DoPrompt specifies the title for the simple input dialog and which input variables are to be included in the dialog.

Flags

/HELP=*helpStr* Sets the help topic or help text that appears when the dialog’s Help button is pressed. *helpStr* can be a help topic and subtopic such as is used by DisplayHelpTopic/K=1 *helpStr*, or it can be text (255 characters max) that is displayed in a subdialog just as if DoAlert 0, *helpStr* had been called, or *helpStr* can be “ ” to remove the Help button.

Parameters

variable is the name of a dialog input variable, which can be real or complex numeric local variable or local string variable, defined by a Prompt statement. You can specify as many as 10 variables.

dialogTitleStr is a string or string expression containing the text for the title of the simple input dialog.

Details

Prompt statements are required to define what variables are to be used and the text for any string expression to accompany or describe the input variable in the dialog. When a DoPrompt variable is missing a Prompt statement, you will get a compilation error. Pop-up string data can not be continued across multiple lines as can be done using Prompt in macros. See **Prompt** for further usage details.

Prompt statements for the input variables used by DoPrompt must come before the DoPrompt statement itself, otherwise, they may be used anywhere within the body of a function. The variables are not required to be input parameters for the function (as is the case for Prompt in macros) and they may be declared within the function body. DoPrompt can accept as many as 10 variables.

Functions can use multiple DoPrompt statements, and Prompt statements can be reused or redefined.

When the user clicks the Cancel button, any new input parameter values are not stored in the variables.

DoPrompt sets the variable V_flag as follows:

V_flag= 0: Continue button clicked.
1: Cancel button clicked.

See Also

The **Simple Input Dialog** on page IV-104, the **Prompt** keyword, and **DisplayHelpTopic**.

DoUpdate

DoUpdate

The DoUpdate operation updates windows and dependent objects.

Details

Call DoUpdate from an Igor procedure to force Igor to update any objects that need updating. Igor updates any graphs, tables or page layouts that need to be updated and also any objects (string variables, numeric variables, waves, controls) that depend on other objects that have changed since the last update.

Igor performs updates automatically when:

- No user-procedure is running.
- An interpreted procedure (Macro, Proc, Window type procedures) is running and PauseUpdate or DelayUpdate is not in effect.

An automatic DoUpdate is not done while a user-defined function is running. You can call DoUpdate from a user-defined function to force Igor to update.

See Also

The **DelayUpdate**, **PauseUpdate**, and **ResumeUpdate** operations.

DoWindow

DoWindow [*flags*] [*windowName*]

The DoWindow operation controls various window parameters and aspects. There are additional forms for DoWindow when the /S or /T flags are used; see the following DoWindow entries.

Parameters

windowName is the name of a graph, table, page layout, notebook, panel or XOP target window.

A window's name is *not* the same as its title. The title is shown in the window's title bar. The name is used to manipulate the window from Igor commands. You can check both the name and the title using the Window Control dialog (in the Arrange submenu of the Window menu).

Flags

/B[= <i>bname</i>]	Moves the specified window to the back (to the bottom of desktop) or behind window <i>bname</i> .
/C	Changes the name of the target window to the specified name. The specified name must not be used for any other object except that it can be the name of an existing window macro.
/C/N	Changes the target window name and creates a new window macro for it. However, /N does nothing if a macro or function is running. /N is not applicable to notebooks.
/D	Deletes the file associated with window, if any (for notebooks only).
/F	Brings the window with the given name to the front (top of desktop).
/H	Specifies the command/history window as the target of the operation. When using /H, <i>windowName</i> must not be specified and only the /B and /HIDE flags are honored. Use /H to bring the command window to the front (top of desktop). Use /H/B to send the history/command window to the bottom of the desktop. Use /H/HIDE to hide or show the command window.
/HIDE= <i>h</i>	Sets hidden state of a window. <i>h</i> =0: Visible. <i>h</i> =1: Hidden. <i>h</i> =?: Determines hidden state (returned in V_flag). You can also read the hidden state using GetWindow and set it using SetWindow .
/K	Kills the window with the given name.
/N	Creates a new window macro for the window with the given name. However, /N does nothing if a macro or function is running. /N is not applicable to notebooks.
/R	Replaces (updates) the window macro for the named window or creates it if it does not yet exist. However, /R does nothing if a macro or function is running. /R is not applicable to notebooks.

<code>/R/K</code>	Replaces (updates) the window macro for the named window or creates it if it does not yet exist and then kills the window. However, <code>/R</code> does nothing if a macro or function is running. <code>/R</code> is not applicable to notebooks.
<code>/W=targWin</code>	Designates <i>targWin</i> as the target window; it also requires that you specify <i>windowName</i> . Use this mainly with floating panels, which are always on top. You can use a subwindow specification of an external subwindow only with the <code>/T</code> flag or without any flags.

Details

DoWindow sets the variable `V_flag` to 1 if there was a window with the specified name after DoWindow executed, to 0 if there was no such window, or to 2 if the window is hidden.

Call DoWindow with no flags to check if a window exists.

When used with the `/N` flag, *windowName* must not conflict with the name of any other object. When used with the `/C` flag, *windowName* must not conflict with the name of any other object except that it can be the name of an existing window macro.

As of Igor Pro 3.13, the `/R` and `/N` flags do nothing when executed while a macro or function is running. This is necessary because changing procedures while they are executing causes unpredictable and undesirable results. However you can use the Execute/P operation to cause the DoWindow command to be executed after procedures are finished running. For example:

```
Function SaveWindowMacro(windowName)
    String windowName                // "" for top graph or table
    if (strlen(windowName) == 0)
        windowName = WinName(0, 3)    // Name of top graph or table
    endif
    String cmd
    sprintf cmd, "DoWindow/R %s", windowName
    Execute/P cmd
End
```

You can use the `/D` flag in conjunction with the `/K` flag to kill a notebook window and delete its associated file, if any. `/D` has no effect on any other type of window and has no effect if the `/K` flag is not present.

Examples

```
DoWindow Graph0                // Set V_flag to 1 if Graph0 window exists.
DoWindow/F Graph0              // Make Graph0 the top/target window.
DoWindow/C MyGraph             // Target window (Graph0) renamed MyGraph.
DoWindow/K Panel0              // Kill the Panel0 window.
DoWindow/H/B                   // Put the history/command window in back.
DoWindow/D/K Notebook2        // Kill Notebook2, delete its file.
```

See Also

The **RenameWindow** operation for renaming windows or subwindows.

The **IgorInfo** function, the **HideProcedures** operation, and the following DoWindow sections.

DoWindow/T

DoWindow /T *windowName*, *windowTitleStr*

The DoWindow /T operation sets the window title for the named window to the specified title.

Details

The title is shown in the window's title bar, and listed in the appropriate Windows submenu. The window *name* is still used to manipulate the window, so, for example, the window name (if *windowName* is a graph or table) is listed in the New Layout dialog; not the title.

You can check both the name and the title using the Window Control dialog (in the Control submenu of the Windows menu).

windowName can be the special `kwFrame` keyword to retitle the "frame" or "application" window that Igor has only under Windows. This is the window that contains Igor's menus and status bar. On Macintosh, `kwFrame` is allowed, but the command does nothing.

The Window Control dialog does not support `kwFrame`. The frame title persists until Igor quits or until it is restored as shown in the example. Setting *windowTitleStr* to "" will restore the normal frame title.

Examples

```
DoWindow/T MyGraph, "My Really Neat Graph"
DoWindow/T kwFrame, "My Igor-based Application"
DoWindow/T kwFrame, "" // restore normal frame title
```

DoWindow/S

DoWindow /N/S=styleMacroName windowName

DoWindow /R/S=styleMacroName windowName

The DoWindow /S operation creates a new “style macro” for the named window, using the specified style macro name. Does not create or replace the window macro for the specified window.

Flags

/N/S=styleMacroName Creates a new style macro with the given name based on the named window.

/R/S=styleMacroName Creates or replaces the style macro with the given name based on the named window.

Details

The /R or /N flag must appear before the /S flag.

If the /S flag is present, the DoWindow operations does *not* create or replace the window macro for the specified window.

As of Igor Pro 3.13, the /R and /N flags do nothing when executed while a macro or function is running. This is necessary because changing procedures while they are executing causes unpredictable and undesirable results.

DoXOPIdle

DoXOPIdle

The DoXOPIdle operation sends an IDLE event to all open XOPs. This operation is very specialized. Generally, only the author of an XOP will need to use this operation.

Details

Some XOPs (External Operation code modules) require IDLE events to perform certain tasks. For example, the SoundInput XOP on the Macintosh transfers sound data from an interrupt buffer to an Igor Named FIFO only during an IDLE event.

Igor does not automatically send IDLE events to XOPs while an Igor program is running. You can call DoXOPIdle from a user-defined program to force Igor to send the event.

DrawAction

DrawAction [/L=layerName/W=winName] keyword = value [, keyword = value ...]

The DrawAction operation deletes, inserts, and reads back a named drawing object group or the entire draw layer.

Parameters

SetDrawEnv can accept multiple *keyword = value* parameters on one line.

beginInsert [=index] Inserts draw commands before or at *index* position or at position specified by getgroup or delete parameters; position otherwise is zero.

commands [=start,stop] Stores commands in S_recreation for draw objects between *start* and *stop* index values, range defined by getgroup, or entire layer otherwise.

delete [=start,stop] Deletes draw objects between *start* and *stop* index values, range defined by getgroup, or entire layer otherwise.

extractOutline [=start,stop] Stores polygon outline between *start* and *stop* index values, range defined by getgroup, or entire layer otherwise. Waves W_PolyX and W_PolyY contain coordinates with NaN separators. V_npnts contains the number of objects. Coordinates are for the first object encountered.

endInsert Terminates insert mode.

getgroup=name Stores first and last index of named group in V_startPos and V_endPos. Use *_all_* to specify the entire layer. Sets V_flag to truth group exists.

Flags

- /L=layerName* Specifies the drawing layer on which to act. *layerName* is one of the drawing layers as specified in **SetDrawLayer**.
- /W=winName* Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Commands stored in `S_recreation` are the same as those that would be generated for the range of objects in the recreation macro for the window but also have comment lines preceding each object of the form:

```
// ;ITEMNO:n;
```

where *n* is the item number of the draw object.

Examples

Create a drawing with a named group:

```
NewPanel /W=(455,124,936,413)
SetDrawEnv fillfgc= (65535,0,0)
DrawRect 58,45,132,103
SetDrawEnv gstart,gname= fred
SetDrawEnv fillfgc= (65535,43690,0)
DrawRect 79,62,154,120
SetDrawEnv arrow= 1
DrawLine 139,70,219,70
SetDrawEnv gstop
SetDrawEnv fillfgc= (0,65535,65535)
DrawRect 95,77,175,138
SetDrawEnv fillfgc= (0,0,65535)
DrawRect 111,91,191,156
```

Get and print commands for the “fred” group:

```
DrawAction getgroup=fred,commands
Print S_recreation
```

prints:

```
// ;ITEMNO:3;
SetDrawEnv gstart,gname= fred
// ;ITEMNO:4;
SetDrawEnv fillfgc= (65535,43690,0)
// ;ITEMNO:5;
DrawRect 79,62,154,120
// ;ITEMNO:6;
SetDrawEnv arrow= 1
// ;ITEMNO:7;
DrawLine 139,70,219,70
// ;ITEMNO:8;
SetDrawEnv gstop
```

Replace group fred (the orange rectangle and the arrow) with a different object. First delete the group and enter insert mode:

```
DrawAction getgroup=fred, delete, begininsert
```

Next draw the replacement:

```
SetDrawEnv gstart,gname= fred
SetDrawEnv fillfgc= (65535,65535,0)
DrawOval 82,62,161,123
SetDrawEnv gstop
```

Lastly exit insert mode:

```
DrawAction endinsert
```

See Also

The **SetDrawEnv** operation and Chapter III-3, **Drawing**.

DrawArc

DrawArc [/W=*winName*/X/Y] *xOrg*, *yOrg*, *arcRadius*, *startAngle*, *stopAngle*

The DrawArc operation draws a circular counterclockwise arc with center at *xOrg* and *yOrg*.

Parameters

(*xOrg*, *yOrg*) defines the center point for the arc in the currently active coordinate system.

Angles are measured in degrees increasing in a counterclockwise direction. The *startAngle* specifies the starting angle for the arc and *stopAngle* specifies the end. If *stopAngle* is equal to *startAngle*, 360° is added to *stopAngle*. Thus, a circle can be drawn using *startAngle* = *stopAngle*.

The *arcRadius* is the radial distance measured in points from (*xOrg*, *yOrg*).

Flags

/W= <i>winName</i>	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/X	Measures <i>arcRadius</i> using the current X-coordinate system. If /Y is also used, the arc may be elliptical.
/Y	Measures <i>arcRadius</i> using the current Y-coordinate system. If /X is also used, the arc may be elliptical.

Details

Arcs honor the current dash pattern and arrowhead setting in the same way as polygons and Beziers. In fact, arcs are implemented using Bezier curves.

Normally, you would create arcs programmatically. If you need to sketch an arc-like object, you should probably use a Bezier curve because it is more flexible and easier to adjust. However, there is one handy feature of arcs that make them useful for manual drawing: the origin can be in any of the supported coordinate systems and the radius is in points.

To draw an arc interactively, see **Arcs and Circles** on page III-70 for instructions.

See Also

The **SetDrawEnv** and **SetDrawLayer** operations.

The **DrawBezier** and **DrawOval** operations.

DrawBezier

DrawBezier [/W=*winName* /ABS] *xOrg*, *yOrg*, *hScaling*, *vScaling*, {*x₀*, *y₀*, *x₁*, *y₁* ...}

DrawBezier [/W=*winName* /ABS] *xOrg*, *yOrg*, *hScaling*, *vScaling*, *xWaveName*,
yWaveName

DrawBezier/A [/W=*winName*] {*x_n*, *y_n*, *x_{n+1}*, *y_{n+1}* ...}

The DrawBezier operation draws a Bezier curve with first point of the curve positioned at *xOrg* and *yOrg*.

Parameters

(*xOrg*, *yOrg*) defines the starting point for the Bezier curve in the currently active coordinate system.

hScaling and *vScaling* set the horizontal and vertical scale factors about the origin, with 1 meaning 100%.

The *xWaveName*, *yWaveName* version of DrawBezier gets data from the named X and Y waves. This connection is maintained so that any changes to either wave will result in updates to the Bezier curve.

To use the version of DrawBezier that takes a literal list of vertices, you place as many vertices as you like on the first line and then use as many /A versions as necessary to define all the vertices.

Flags

/A	Appends the given vertices to the currently open Bezier (freshly drawn or current selection).
/ABS	Suppresses the default subtraction of the first point from the rest of the data.

/W=winName Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Data waves defining Bezier curves must have $1+3*n$ data points. Every third data point is an anchor point and lies on the curve; intervening points are control points that define the direction of the curve relative to the adjacent anchor point.

Normally, you should create and edit a Bezier curve using drawing tools, and not calculate values. See **Polygon Tool** on page III-71 for instructions.

As of Igor Pro 5.02, you can specify the */ABS* flag to suppress the default subtraction of the first point. Also, you can now insert NaN values to break a bezier into pieces.

To change just the origin and scale without respecifying the data use:

`DrawBezier xOrg, yOrg, hScaling, vScaling, { }`

To delete an anchor point, press Option (*Macintosh*) or Alt (*Windows*) and then click on the anchor. To insert a new anchor, click on the curve between anchor points.

Example

Create a half circle approximation from three anchor points starting at the 12 o'clock position, with an anchor at the 3 o'clock position, and the last at the 6 o'clock position using explicit values:

```
// Set plot relative coords, 0-1, no fill
SetDrawEnv xcoord=pre1, ycoord=pre1, fillpat= 0, save

Variable len= 0.275           // control point length = 0.55 * radius for a circle
// Starting anchor point has only a trailing control point
Variable anchor0x= 0.5, anchor0y=1           // starting point at 6 o'clock
Variable t0x= 0.5+len, t0y= 1                // trailing control point

// second anchor point has both leading and trailing control points
Variable l1x=1, l1y = 0.5+len                // leading control point
Variable anchor1x= 1, anchor1y= 0.5          // 3 o'clock anchor
Variable t1x=1, t1y = 0.5-len                // trailing control point

// Last (3rd) anchor point has only a leading control point
Variable l2x=0.5+len, l2y = 0                // leading control point
Variable anchor2x= 0.5, anchor2y= 0          // 6 o'clock

// One command per anchor for clarity
DrawBezier anchor0x, anchor0y, 1,1, {anchor0x, anchor0y, t0x, t0y}
DrawBezier/A {l1x, l1y, anchor1x, anchor1y, t1x, t1y}
DrawBezier/A {l2x, l2y, anchor2x, anchor2y}
```

To draw using waves:

```
Make/O bezierX= {anchor0x, t0x, l1x, anchor1x, t1x, l2x, anchor2x }
Make/O bezierY= {anchor0y, t0y, l1y, anchor1y, t1y, l2y, anchor2y }
DrawBezier anchor0x, anchor0y, 1,1, bezierX, bezierY
```

See Also

Polygon Tool on page III-71 for discussion on creating Beziers. **DrawPoly** and **DrawBezier** on page III-79 and the **SetDrawEnv** and **SetDrawLayer** operations.

The **DrawArc** and **DrawPoly** operations.

DrawLine

DrawLine [*/W=winName*] *x0, y0, x1, y1*

The DrawLine operation draws a line in the target graph, layout or control panel from (*x0,y0*) to (*x1,y1*).

Flags

/W=winName Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

DrawOval

Details

The coordinate system as well as the line's thickness, color, dash pattern and other properties are determined by the current drawing environment. The line is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

The SetDrawEnv and SetDrawLayer operations.

DrawOval

DrawOval [/W=*winName*] *left, top, right, bottom*

The DrawOval operation draws an oval in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The coordinate system as well as the oval's thickness, color, dash pattern and other properties are determined by the current drawing environment (note that you cannot draw dashed ovals). The oval is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

The SetDrawEnv and SetDrawLayer operations.

DrawPICT

DrawPICT [/W=*winName*] [/RABS] *left, top, hScaling, vScaling, pictName*

The DrawPICT operation draws the named picture in the target graph, layout or control panel. The *left* and *top* parameters set the position of the top/left corner of the picture. *hScaling* and *vScaling* set the horizontal and vertical scale factors with 1 meaning 100%.

Flags

/RABS Draws the named picture using absolute scaling. In this mode, it draws the picture in the rectangle defined by *left* and *top* for point (x0,y0), and by *hScaling* and *vScaling* for point (x1,y1), respectively.
/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The coordinate system for the left and top parameters is determined by the current drawing environment. The PICT is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

The SetDrawEnv and SetDrawLayer operations.

DrawPoly

DrawPoly [/W=*winName* /ABS] *xorg, yorg, hScaling, vScaling, xWaveName, yWaveName*

DrawPoly [/W=*winName* /ABS] *xorg, yorg, hScaling, vScaling, {x₀, y₀, x₁, y₁ ...}*

DrawPoly/A [/W=*winName*] {*x_n, y_n, x_{n+1}, y_{n+1} ...*}

The DrawPoly operation draws a polygon in the target graph, layout or control panel.

Parameters

(*xorg, yorg*) defines the starting point for the polygon in the currently active coordinate system.

hScaling and *vScaling* set the horizontal and vertical scale factors, with 1 meaning 100%.

The *xWaveName*, *yWaveName* version of DrawPoly gets data from those X and Y waves. This connection is maintained so that changes to either wave will update the polygon.

The DrawPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

To use the version of DrawPoly that takes a literal list of vertices, you place as many vertices as you like on the first line and then use as many /A versions as necessary to define all the vertices.

Flags

/A	Appends the given vertices to the currently open polygon (freshly drawn or current selection).
/ABS	Suppresses the default subtraction of the first point from the rest of the data.
/W= <i>winName</i>	Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Because *xorg* and *yorg* define the location of the starting vertex of the poly, adding or subtracting a constant from the vertices will have no effect. The first XY pair in the {*x0*, *y0*, *x1*, *y1*,...} vertex list will appear at (*xorg*,*yorg*) regardless of the value of *x0* and *y0*. *x0* and *y0* merely serve to set a reference point for the list of vertices. Subsequent vertices are relative to (*x0*,*y0*).

To keep your mental health intact, we recommend that you specify (*x0*,*y0*) as (0,0) so that all the following vertices are offsets from that origin. Then (*xorg*,*yorg*) sets the position of the polygon and all of the vertices in the list are relative to that origin.

An alternate method is to use the same values for (*x0*,*y0*) as for (*xorg*,*yorg*) if you consider the vertices to be “absolute” coordinates.

As of Igor Pro 5.02, you can specify the /ABS flag to suppress the subtraction of the first point. Also, you can now insert NaN values to break a polygon into pieces.

To change just the origin and scale of the currently open polygon — without having to respecify the data — use:

```
DrawPoly xorg, yorg, hScaling, vScaling,{}
```

The coordinate system as well as the polygon’s thickness, color, dash pattern and other properties are determined by the current drawing environment. The polygon is drawn in the current draw layer for the window, as determined by SetDrawLayer.

Examples

Here are some commands to draw some small triangles using absolute drawing coordinates (see **SetDrawEnv**).

```
Display // make a new empty graph
//Draw one triangle, starting at 50,50 at 100% scaling
SetDrawEnv xcoord= abs,ycoord= abs
DrawPoly 50,50,1,1, {0,0,10,10,-10,10,0,0}
//Draw second triangle below and to the right, same size and shape
SetDrawEnv xcoord= abs,ycoord= abs
DrawPoly 100,100,1,1, {0,0,10,10,-10,10,0,0}
```

DrawRect

DrawRect [/W=*winName*] *left*, *top*, *right*, *bottom*

The DrawRect operation draws a rectangle in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The coordinate system as well as the rectangle's thickness, color, dash pattern and other properties are determined by the current drawing environment. The rectangle is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

The SetDrawEnv and SetDrawLayer operations.

DrawRRect

DrawRRect [/W=*winName*] *left*, *top*, *right*, *bottom*

The DrawRRect operation draws a rounded rectangle in the target graph, layout or control panel within the rectangle defined by *left*, *top*, *right*, and *bottom*.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The coordinate system as well as the rectangle's rounding, thickness, color, dash pattern and other properties are determined by the current drawing environment. The rounded rectangle is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

The SetDrawEnv and SetDrawLayer operations.

DrawText

DrawText [/W=*winName*] *x0*, *y0*, *textStr*

The DrawText operation draws the specified text in the target graph, layout or control panel. The position of the text is defined by (*x0*, *y0*) along with the current environment settings of textxjust, textyjust and textrot parameters of SetDrawEnv.

Flags

/W=*winName* Draws to the named window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The coordinate system as well as the text's font, size, style and other properties are determined by the current drawing environment. The text is drawn in the current draw layer for the window, as determined by SetDrawLayer.

See Also

The SetDrawEnv and SetDrawLayer operations.

DSPDetrend

DSPDetrend [*flags*] *srcWave*

The DSPDetrend operation removes from *srcWave* a trend defined by the best fit of the specified function to the data in *srcWave*.

Flags

/F= <i>function</i>	<i>function</i> is the name of a built-in curve fitting function: gauss, lor, exp, dblexp, sin, line, poly (requires /P flag), hillEquation, sigmoid, power, lognormal, poly2d (requires /P flag), gauss2d. If <i>function</i> is unspecified, the defaults are line if <i>srcWave</i> is 1D or poly2d if <i>srcWave</i> is 2D.
/M= <i>maskWave</i>	Detrending will only affect points that are nonzero in <i>maskWave</i> . Note that <i>maskWave</i> must have the same dimensionality as <i>srcWave</i> .
/P= <i>polyOrder</i>	Specifies polynomial order for poly or poly2d functions (see CurveFit for details). By default <i>polyOrder</i> =3 for the 1D case and <i>polyOrder</i> =1 for the 2D case.
/Q	Quiet mode; no error reporting.

Details

DSPDetrend sets V_flag to zero when the operation succeeds, otherwise it will be set to -1 or will contain an error code from the curve fitting routines. Results are saved in the wave W_Detrend (for 1D input) or M_Detrend (for 2D input) in the current data folder. If a wave by that name already exists in the current data folder it will be overwritten.

See Also

CurveFit for more information about V_FitQuitReason and the built-in fitting functions.

DSPPeriodogram

DSPPeriodogram [*flags*] *srcWave* [*srcWave1*]

The DSPPeriodogram operation calculates the periodogram of *srcWave*. It does not test the dimensionality of the wave and it considers the wave to be 1D.

$$\text{Periodogram} = \frac{|\text{abs}(F(\text{signal}))|^2}{N} \text{ where } F() \text{ is the Fourier transform of the signal.}$$

The result will be stored in the wave W_Periodogram in the current data folder.

To compute the cross-spectral density of two waves, specify the second wave using the optional *srcWave1* parameter. In this case, W_Periodogram will be complex, and the /dB and /dBR flags will not apply.

Flags

/dB	Expresses results in dB using the maximum value as reference.
/dBR= <i>ref</i>	Express the results in dB using the specified <i>ref</i> value.
/NODC= <i>val</i>	Suppresses the DC term <i>val</i> =1: Removes the DC by subtracting the average value of the signal before processing and before applying any window function (see /Win below). <i>val</i> =2: Suppresses the DC term by setting it equal to the second term in the array. <i>val</i> =0: Computes the DC term using the FFT (default).
/NOR= <i>value</i>	Sets the normalization, N, in the periodogram equation. By default, it is the number of data points. <i>value</i> =1: Skips default normalization by the number of data points, but you can also set it to any other value that is substituted for N.
/Q	Quiet mode; suppresses error messages. For any errors, V_flag will be set to -1.
/R=[<i>startPt</i> , <i>endPt</i>]	Calculates the periodogram for a limited range of the wave. <i>startPt</i> and <i>endPt</i> are expressed in terms of point numbers in <i>srcWave</i> .
/R=(<i>startX</i> , <i>endX</i>)	Calculates the periodogram for a limited range of the wave. <i>startX</i> and <i>endX</i> are expressed in terms of x-values. Note that this option will convert your x-specifications to point numbers and some roundoff may occur.

Duplicate

/Win=windowKind Specifies the window type. If you omit the */W* flag, *DSPPeriodogram* uses a rectangular window for the full wave or the range of data selected by the */R* flag. Choices for *windowKind* are:
Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.
See **FFT** for window definition details.

See Also

The **ImageWindow** operation for 2D windowing applications. **FFT** for window equations and details. The **Hanning** operation.

References

For more information about the use of window functions see:

Harris, F.J., On the use of windows for harmonic analysis with the discrete Fourier Transform, *Proc, IEEE*, 66, 51-83, 1978.

Duplicate

Duplicate [*flags*][*type flags*] *srcWaveName*, *destWaveName* [, *destWaveName*]...

The Duplicate operation creates new waves, the names of which are specified by *destWaveNames* and the contents, data type and scaling of which are identical to *srcWaveName*.

Parameters

srcWaveName must be the name of an existing wave.

The *destWaveNames* should be wave names not currently in use unless the */O* flag is used to overwrite existing waves.

Flags

/O Overwrites existing waves with the same name as *destWaveName*.
/R=(startX,endX) Specifies an X range in the source wave from which the destination wave is created.
/R=(startX,endX)(startY,endY) Specifies both X and Y range. Further dimensions are constructed analogously.
/R=[startP,endP] Specifies a row range in the source wave from which the destination wave is created. Further dimensions are constructed just like the scaled dimension ranges.

In the range specifications, a * for the end means duplicate to the end. You can also simply leave out the end specification. To include all of a given dimension, use */R=[]*. If you leave off higher dimensions, all those dimensions are duplicated. That is, */R=[1, 5]* for a 2D wave is equivalent to */R=[1, 5] []*.

Type Flags (used only in functions)

Duplicate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Details

If */R* is omitted, the entire wave is duplicated.

When used in user-defined functions, Duplicate can also take the */B*, */C*, */D*, */I*, */S*, */U*, */W*, and */T* flags. This does not affect the result of the Duplicate operation; these flags are used only to identify what kind of wave is expected at runtime.

This information is used if, later in the function, you create a wave assignment statement using a duplicated wave as the destination:

```
Function DupIt(wv)
    Wave/C wv                                //complex wave
    Duplicate/O/C wv,dupWv                    //tell Igor that dupWv is complex
    dupWv[0]=cmplx(5.0,1.0)                  //no error, because dupWv known complex
    ...
```

If Duplicate did not have the /C flag, Igor would complain with a “function not available for this number type” message when it tried to compile the assignment of dupWv to the result of the cmplx function.

Warning: Under some circumstances, such as in loops in user-defined functions, Duplicate may exhibit undesired behavior.

When you use

```
Duplicate/O srcWave, DestWaveName
```

in a user-defined function, it creates a local WAVE variable named *DestWaveName* at compile time. At runtime, if the WAVE variable is NULL, it creates a wave of the same name in the current data folder. If, however, the WAVE variable is not NULL, as it would be in a loop, then the referenced wave will be overwritten no matter where it is located. If the desired behavior is to create (or overwrite) a wave in the current data folder, you should use one of the following two methods:

```
Duplicate/O srcWave, $"DestWaveName"
WAVE DestWaveName // only if you need to reference dest wave
```

or

```
Duplicate/O srcWave, DestWaveName
// then after you are finished using DestWaveName...
WAVE DestWaveName=$""
```

See Also

The **Rename** operation.

DuplicateDataFolder

DuplicateDataFolder *sourceDataFolderSpec*, *destDataFolderSpec*

The DuplicateDataFolder operation makes a copy of the source data folder and everything in it and places the copy at the specified location with the specified name.

Parameters

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

destDataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name. If just a data folder name is used then the new data folder is created in the current data folder.

Details

An error is issued if the destination is contained within the source data folder.

Examples

Create a copy of foo named foo2 in bar:

```
DuplicateDataFolder foo,:bar:foo2
```

See Also

See the **MoveDataFolder** operation. Chapter II-8, **Data Folders**.

DWT

DWT [*flags*] *srcWaveName*, *destWaveName*

The DWT operation performs discrete wavelet transform on the input wave *srcWaveName*. The operation works on one or more dimensions only as long as the number of elements in each dimension is a power of 2 or when the /P flag is specified

Flags

- /D Denoises the source wave. Performs the specified wavelet transform in the forward direction. It then zeros all transform coefficients whose magnitude fall below a given percentage (specified by the /V flag) of the maximum magnitude of the transform. It then performs the inverse transform placing the result in *destWaveName*. The /I flag is incompatible with the /D flag.
- /I Perform the inverse wavelet transform. The /S and /D flags are incompatible with the /I flag.
- /N=*num* Specifies the number of wavelet coefficients. See /T flag for supported combinations.
- /P=*num* *num*=1: Adds zero padding to the end of the dimension up to nearest power of 2 when the number of data elements in a given dimension of *srcWaveName* is not a power of 2.

num=2: Uses zero padding to compute the transform, but the resulting wave is truncated to the length of the input wave.

/S Smooths the source wave. This performs the specified wavelet transform in the forward direction. It then zeros all transform coefficients except those between 0 and the cut-off value (specified in % by */V* flag). It then performs the inverse transform placing the result in *destWaveName*. The */I* flag is incompatible with the */S* flag.

/T=type Performs the wavelet transform specified by *type*. The following table gives the transform name with the *type* code for the transform and the allowed values of the *num* parameter used with the */N* flag. "NA" means that the */N* flag is not applicable to the corresponding transform.

Wavelet Transform	<i>type</i>	<i>num</i>
Daubechies	1 (default)	4, 6, 8, 10, 12, 20
Haar	2	NA
Battle-Lemarie	4	NA
Burt-Adelson	8	NA
Coifman	16	2, 4, 6
Pseudo-Coifman	32	NA
splines	64	1 (2-2), 2 (2-4), 3 (3-3), 4 (3-7)

/V=value Specifies the degree of smoothing with the */S* and */D* flags only.
For */S*, *value* gives the cutoff as a percentage of data points above which coefficients are set to zero. For */D*, *value* specifies the percentage of the maximum magnitude of the transform such that coefficients smaller than this value are set to zero.

Details

If *destWaveName* exists, DWT overwrites it; if it does not exist, DWT creates it.

When used in a function, the DWT operation automatically creates a wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-53 for details.

If *destWaveName* is not specified, the DWT operation stores the results in *W_DWT* for 1D waves and *M_DWT* for higher dimensions.

When working with 1D waves, the transform results are packed such that the higher half of each array contains the detail components and the lower half contains the smooth components and each successive scale is packed in the lower elements. For example, if the source wave contains 128 points then the lowest scale results are stored in elements 64-127, the next scale (power of 2) are stored from 32-63, the following scale from 16-31 etc.

Example

```
Make/O/N=1024 testData=sin(x/100)+gnoise(0.05)
DWT /S/N=20/V=25 testData, smoothedData
```

For continuous wavelet transforms use the **CWT** operation. See the **FFT** operation.

For further discussion and examples see **Discrete Wavelet Transform** on page III-243.

The *e* function returns the base of the natural logarithm system (2.7182818...).

EdgeStats

EdgeStats [*flags*] *waveName*

The EdgeStats operation produces simple statistics on a region of a wave that is expected to contain a single edge. If more than one edge exists, EdgeStats works on the first one found.

Flags

/A= <i>avgPts</i>	Determines <i>startLevel</i> and <i>endLevel</i> automatically by averaging <i>avgPts</i> points at centered at <i>startX</i> and <i>endX</i> . Default is /A=1.
/B= <i>box</i>	Sets box size for sliding average. This should be an odd number. If /B= <i>box</i> is omitted or <i>box</i> equals 1, no averaging is done.
/F= <i>frac</i>	Specifies levels 1, 2 and 3 as a fraction of (<i>endLevel</i> - <i>startLevel</i>): $\text{level1} = \text{frac} * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ $\text{level2} = 0.5 * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ $\text{level3} = (1 - \text{frac}) * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ <p>The default value for <i>frac</i> is 0.1 which makes level1 the 10% level, level2 the 50% level and level3 the 90% level. <i>frac</i> must be between 0 and 0.5.</p>
/L=(<i>startLevel</i> , <i>endLevel</i>)	Sets <i>startLevel</i> and <i>endLevel</i> explicitly. If omitted, they are determined automatically. See /A.
/P	Output edge locations (see Details) are returned as point numbers. If /P is omitted, edge locations are returned as X values.
/Q	Prevents results from being printed in history and prevents error if edge is not found.
/R=(<i>startX</i> , <i>endX</i>)	Specifies an X range of the wave to search. You may exchange <i>startX</i> and <i>endX</i> to reverse the search direction.
/R=[<i>startP</i> , <i>endP</i>]	Specifies a point range of the wave to search. You may exchange <i>startP</i> and <i>endP</i> to reverse the search direction. If /R is omitted, the entire wave is searched.
/T= <i>dx</i>	Forces search in two directions for a possibly more accurate result. <i>dx</i> controls where the second search starts.

Details

The /B=*box*, /T=*dx*, /P, and /Q flags behave the same as for the **FindLevel** operation.

EdgeStats considers a region of the input wave between two X locations, called *startX* and *endX*. *startX* and *endX* are set by the /R=(*startX*, *endX*) flag. If this flag is missing, *startX* and *endX* default to the start and end of the entire wave. *startX* can be greater than *endX* so that the search for an edge can proceed from the “right” to the “left”.

The diagram above shows the default search direction, from the “left” (lower point numbers) of the wave toward the “right” (higher point numbers).

The *startLevel* and *endLevel* values define the base levels of the edge. You can explicitly set these levels with the /L=(*startLevel*, *endLevel*) flag or you can let EdgeStats find the base levels for you by using the /A=*avgPts* flag which averages points around *startX* and *endX*.

Edit

Given *startLevel* and *endLevel* and a *frac* value (see the */F=frac* flag) *EdgeStats* defines level1, level2 and level3 as shown in the diagram above. With the default *frac* value of 0.1, level1 is the 10% point, level2 is the 50% point and level3 is the 90% point.

With these levels defined, *EdgeStats* searches the wave from *startX* to *endX* looking for level2. Having found it, it then searches for level1 and level3. It returns results via variables described below.

EdgeStats sets the following variables:

<i>V_flag</i>	0: All three level crossings were found. 1: One or two level crossings were found. 2: No level crossings were found.
<i>V_EdgeLoc1</i>	X location of level1.
<i>V_EdgeLoc2</i>	X location of level2.
<i>V_EdgeLoc3</i>	X location of level3.
<i>V_EdgeLv10</i>	<i>startLevel</i> value.
<i>V_EdgeLv11</i>	level1 value.
<i>V_EdgeLv12</i>	level2 value.
<i>V_EdgeLv13</i>	level3 value.
<i>V_EdgeLv14</i>	<i>endLevel</i> value.
<i>V_EdgeAmp4_0</i>	Edge amplitude (<i>endLevel</i> - <i>startLevel</i>).
<i>V_EdgeDLoc3_1</i>	Edge width (x distance between point 1 and point 3).
<i>V_EdgeSlope3_1</i>	Edge slope (straight line slope from point 1 and point 3).

These X locations and distances are in terms of the X scaling of the named wave unless you use the */P* flag, in which case they are in terms of point number.

The *EdgeStats* operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **FindLevel** operation for use of the */B=box*, */T=dx*, */P* and */Q* flags, and **PulseStats**.

Edit

Edit [*flags*] [*columnSpec* [, *columnSpec*]...][*as titleStr*]

The *Edit* operation creates a table window or subwindow containing the specified columns.

Parameters

columnSpec is usually just the name of a wave. If no *columnSpecs* are given, *Edit* creates an empty table.

Column specifications are wave names optionally followed by one of the suffixes:

- .i Index values.
- .l Dimension labels.
- .d Data values.
- .id Index and data values.
- .ld Dimension labels and data values.

If the wave is complex, the wave names may be followed by *.real* or *.imag* suffixes. However, as of Igor Pro 3.0, both the real and imaginary columns are added to the table together — you can not add one without the other — so using these suffixes is discouraged.

Historical Note:

Prior to Igor Pro 3.0, only 1D waves were supported. We called index values “X values” and used the suffix “.x” instead of “.i”. We called data values “Y values” and used the suffix “.y” instead of “.d”. For backward compatibility, Igor accepts “.x” in place of “.i” and “.y” in place of “.d”.

titleStr is a string expression containing the table’s title. If not specified, Igor will provide one which identifies the columns displayed in the table.

Flags

/HIDE=h Shows (*h* = 1; default) or hides (*h* = 0) the window.

<code>/HOST=<i>hcSpec</i></code>	Embeds the new table in the specified host window or subwindow <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
<code>/I</code>	Specifies that <code>/W</code> coordinates are in inches.
<code>/K=<i>k</i></code>	Sets behavior when closing the table. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
<code>/M</code>	Specifies that <code>/W</code> coordinates are in centimeters.
<code>/N=<i>name</i></code>	Requests that the created table have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, <code>S_name</code> is set to the chosen table name. Use <code>DoWindow/K name</code> to ensure that <i>name</i> is available.
<code>/W=(<i>left,top,right,bottom</i>)</code>	Gives the table a specific location and size on the screen. Coordinates for <code>/W</code> are in points unless <code>/I</code> or <code>/M</code> are specified before <code>/W</code> . When used with the <code>/HOST</code> flag, the specified location coordinates of the sides can have one of two possible meanings: 1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size. 2) When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.

Details

You can not change dimension index values shown in a table. Use the Change Wave Scaling dialog or the **SetScale** operation.

If `/N` is not used, Edit automatically assigns to the table window a name of the form "Tablen", where *n* is some integer. In a function or macro, the assigned name is stored in the `S_name` string. This is the name you can use to refer to the table from a procedure. Use the **RenameWindow** operation to rename the graph.

Examples

These examples assume that the waves are 1D.

```
Edit myWave,otherWave      // 2 columns: data values from each wave
Edit myWave.id              // 2 columns: x and data values
Edit cmplxWave              // 2 columns: real and imaginary data values
Edit cmplxWave.i            // One column: x values
```

The following examples illustrates the use of column name suffixes in procedures when the name of the wave is in a string variable.

```
Macro TestEdit()
  String w = "wave0"
  Edit $w                  // edit data values
  Edit $w.i                // show index values
  Edit $w.id               // index and data values
End
```

Note that the suffix, if any, must not be stored in the string. In a user-defined function, the syntax would be slightly different:

```
Function TestEditFunction()
  Wave w = $"wave0"
  Edit w                   // no $, because w is name, not string
  Edit w.i                 // show index values
  Edit w.id                // index and data values
End
```

See Also

The **DoWindow** operation. For a description of how tables are used, see Chapter II-11, **Tables**.

ei

ei(*x*)

The `ei` function returns the value of the exponential integral $Ei(x)$:

End

$$E(i) = P \int_{-\infty}^x \frac{e^{-t}}{t} dt \quad x > 0 \text{ where } P \text{ denotes the principal value of the integral.}$$

endtry

endtry

The endtry flow control keyword defines the end of a try-catch-entry flow control construct.

See Also

The **try-catch-endtry** flow control statement for details.

enoise

enoise(*num* [, *RNG*])

The enoise function returns a random value such that an infinite number of such values would be evenly distributed between *-num* and *num*.

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never repeat the same sequence. If you want repeatable “random” numbers, use **SetRandomSeed**.

The optional parameter *RNG* selects one of two different pseudo-random number generators. If omitted, the default is 1. The *RNG*’s are:

<i>RNG</i>	Description
1	Linear Congruential generator by L’Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <i>Numerical Recipes</i> as the function ran2 (). This option has nearly 23^2 distinct values and the sequence of random numbers has a period in excess of 10^{18} .
2	Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of $2^{19937}-1$.

equalWaves

equalWaves(waveA, waveB, selector [, tolerance])

The equalWaves function compares *waveA* to *waveB*. Each wave can be of any data type. It returns 1 for equality and zero otherwise.

Use the *selector* parameter to determine which aspects of the wave are compared. You can add *selector* values to test more than one field at a time or pass -1 to compare all aspects.

<i>selector</i>	Field Compared
1	Wave data
2	Wave data type
4	Wave scaling
8	Data units
16	Dimension units
32	Dimension labels
64	Wave note
128	Wave lock state
256	Data full scale
512	Dimension sizes

If you use the selectors for wave data, wave scaling, dimension units, dimension labels or dimension sizes, EqualWaves will return zero if the waves have unequal dimension sizes. The other selectors do not require equal dimension sizes.

If you are testing for equality of wave data and if the *tolerance* is specified, it must be a positive number. The function returns 1 for equality if the data satisfies:

$$\sum_i (\text{waveA}[i] - \text{waveB}[i])^2 < \text{tolerance}.$$

If *tolerance* is not specified, the default is 10^{-8} .

erf

erf(num [, accuracy])

The erf function returns the error function of *num*.

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the error function is

$$\operatorname{erf}(z) = \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}, \frac{3}{2}, -z^2\right) \text{ where } {}_1F_1\left(\frac{1}{2}, \frac{3}{2}, -z^2\right)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7} , that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$ be less than 10^{-7} .

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than about 2×10^{-7} .

If *accuracy* is present, erf can achieve fractional accuracy better than 8×10^{-16} for *num* as small as 10^{-3} . For smaller *num* fractional accuracy is better than 5×10^{-15} .

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to 10^{-16} erfc takes about 50% more time than with *accuracy* set to 10^{-7} .

See Also

The **erfc**, **dawson**, and **inverseErf** functions.

erfc

erfc(num [, accuracy])

The erfc function returns the complementary error function of *num* ($\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$). Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the complementary error function is

$$\operatorname{erfc}(z) = 1 - \operatorname{erf}(z) = 1 - \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}, \frac{3}{2}, -z^2\right) \text{ where } {}_1F_1\left(\frac{1}{2}, \frac{3}{2}, -z^2\right)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7} , that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$ be less than 10^{-7} .

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than 2×10^{-7} .

If *accuracy* is present, erfc can achieve fractional accuracy better than 2×10^{-16} for *num* up to 1. From *num* = 1 to 10 fractional accuracy is better than 2×10^{-15} .

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to 10^{-16} erfc takes about 50% more time than with *accuracy* set to 10^{-7} .

See Also

The **erf**, **inverseErfc**, and **dawson** functions.

ErrorBars

ErrorBars [flags] traceName, mode [errorSpecification]

The ErrorBars operation adds or removes error bars to or from the named trace in the specified graph.

The “error bars” are lines that extend from each data point to “caps”. The length of the line (or “bar”) is usually used to bracket a measured value by the amount of uncertainty, or “error” in the measurement.

Parameters

traceName is usually the name of a wave. If a wave is displayed more than once in a graph, the instance number can be appended to identify which instance to apply error bars to. For instance, wave0#2 refers to the third instance of wave0 displayed in the top graph (wave0, or wave0#0, is the first instance).

A string containing *traceName* can be used with the \$ operator to specify *traceName*.

mode is one of the following keywords:

OFF	No error bars.
X	Horizontal error bars only.
Y	Vertical error bars only.
XY	Horizontal and vertical error bars.
BOX	Box error bars.

For any *mode* other than OFF, there is an *errorSpecification* whose format is **keyword** [= *value*]. The *errorSpecification* keywords are:

pct	Percent.
sqrt	Square root.
const	Constant.
wave	Arbitrary error values. You can use subranges; see Subrange Display Syntax on page II-267.

See the examples for the values that correspond to these *mode* and *errorSpecification* keywords. See the diagram below. *mode* and *errorSpecification* control only the lengths of the horizontal and vertical lines (the “bars”) to the “caps”. All other sizes and thicknesses are controlled by the flags.

Sizes controlled by *mode* and *errorSpecification*

Sizes controlled by flag values

XY *mode* Error Bars

Flags

/L= <i>lineThick</i>	Specifies the thickness of both the X and Y error bars drawn from the point on the wave to the caps.
/T= <i>thick</i>	Specifies the thickness of both the X and Y error bar “caps”.
/W= <i>winName</i>	Changes error bars in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/X= <i>xWidth</i>	Specifies the width (height, actually) of the caps to the left or right of the point.
/Y= <i>yWidth</i>	Specifies the width of the caps above or below the point.

The thicknesses and widths are in units of points. The thickness parameters need not be integers. Although only integral thicknesses can be displayed exactly on the screen, nonintegral thicknesses are produced properly on high resolution hard copy devices. Use /T=0 to completely suppress the caps and /L=0 to completely suppress the lines to the caps.

Details

If a point in *traceName* is not within the graph’s axes (because the graph has been expanded) then that point’s error bars are not shown. If a wave specifying error values for *traceName* is shorter than the wave displayed by *traceName* then the last value of the error wave is used for the unavailable points. If a point in an error wave contains NaN (Not a Number) then the half-bar associated with that point is not shown.

Execute

Examples

<code>ErrorBars wave1,XY pct=10,pct=5</code>	X and Y error bars, X is 10% of <code>wave1</code> , Y is 5%
<code>ErrorBars wave1,X sqrt</code>	X error bars only, square root of <code>wave1</code>
<code>ErrorBars wave1,Y const=4.3</code>	Y error bars only, constant error value = 4.3
<code>ErrorBars wave1,BOX pct=10,pct=5</code>	error box, 10% in horizontal direction 5% in vertical direction
<code>ErrorBars wave1,Y wave=(w1,w2)</code>	Y error bars only, arbitrary error values wave <code>w1</code> = errors for upper (Y+) bars wave <code>w2</code> = errors for lower (Y-) bars
<code>ErrorBars wave1,Y wave=(,w2)</code>	Y error bars only, no upper (Y+) error bars wave <code>w2</code> = errors for lower bars
<code>ErrorBars wave1,OFF</code>	turns error bars for <code>wave1</code> off

Execute

Execute [/Q/Z] *cmdStr*

The Execute operation executes the contents of *cmdStr* as if it had been typed in the command line.

The most common use of Execute is to call a macro or an external operation from a user-defined function. This is necessary because Igor does not allow you to make such calls directly.

When the /Z flag is used, an error code is placed in `V_flag`. The error code will be -1 if a missing parameter style macro is called and the user clicks Quit Macro, or zero if there was no error.

Flags

/Q	Command is not printed in the command line or history area.
/Z	Errors are not fatal and error dialogs are suppressed.

Details

Because the command line and command buffer are limited to 400 characters on a single line, *cmdStr* is likewise limited to a maximum of 400 executable characters.

Do not reference local variables in *cmdStr*. The command is not executed in the local environment provided by a macro or user-defined function.

Execute can accept a string expression containing a macro. The string must start with Macro, Proc, or Window, and must follow the normal rules for macros. All lines must be terminated with carriage returns including the last line. The name of the macro is not important but must exist. Errors will be reported except when using the /Z flag, which will assign `V_Flag` a nonzero number in an error condition.

Examples

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. This prints the string to the history for debugging:

```
String cmd
sprintf cmd, "GBLoadWave/P=%s/S=%d \"%s\"", pathName, skipCount, fileName
Print cmd          // For debugging
Execute cmd
```

Execute with a macro:

```
Execute "Macro junk(a,b)\rvariable a=1,b=2\r\rprint \"hello from macro\",a,b\rEnd\r"
```

See Also

The **Execute Operation** on page IV-147 for other uses.

Execute/P

Execute/P [/Q/Z] *cmdStr*

Execute/P is similar to Execute except the command string, *cmdStr*, is not immediately executed but rather is posted to an operation queue. Items in the operation queue execute only when nothing else is happening. Macros and functions must not be running and the command line must be empty.

Flags

- /Q Command is not printed in the command line or history area.
/Z No error reporting.

See Also

Operation Queue on page IV-195 for more details on using Execute/P with the operation queue.

ExecuteScriptText

ExecuteScriptText [*flags*] *textStr*

The ExecuteScriptText operation passes your text to Apple's scripting subsystem for compilation and execution or to the Windows command line.

If the /Z flag is used then a variable named V_flag is created and is set to a nonzero value if an error was generated by the script or zero if no error. The error is not reported to Igor if the /Z flag is used.

On Macintosh: Any results, including error messages, are placed in a string variable named S_value. The /B flag is ignored. The /W flag is ignored and ExecuteScriptText does not return until the script is finished.

On Windows: *textStr* contains the name of the executable file with optional Windows-style path and optional arguments:

`[path]executableName [.exe] [arg1]...`

If *path* is not given and *executableName* ends with ".exe" or with no extension, Igor locates the executable by searching first the registry and then along the PATH environment variable. If not found, then the Igor Pro Folder directory is assumed.

`ExecuteScriptText "calc" // calc.exe, calculator`

When calling a batch file or other non-*.exe file, supply the full path. If the path (or file name) contains spaces put quotes in the string:

`ExecuteScriptText "\"C:\\Program Files\\my.bat\""`

If you use the /W=*waitTime* flag with a positive value for *waitTime*, ExecuteScriptText waits up to that many seconds after submitting the command for the process started by the command to terminate. If the process fails to terminate within that period of time, ExecuteScriptText returns an error.

If you omit the /W flag or if you pass zero for *waitTime*, for GUI programs, ExecuteScriptText returns when the program begins processing messages. For non-GUI programs, ExecuteScriptText returns as soon as the OS returns control to Igor after Igor submits the script text to the OS.

Igor currently can not write to a console application's standard input nor read from its standard output.

Use the /B flag to run the command in the background, keeping Igor as the active application.

S_value is always set to "".

Parameters

textStr must contain a valid AppleScript program or Windows command line.

Flags

- /B Execute Windows command line as a background task.
/W=*waitTime* This flag is accepted on any platform but has an effect only on Windows. See the description above.
/Z Script errors are not fatal.

Examples

On Macintosh, convert *file.PICT* to *file.GIF*:

```
String ae = "tell application \"clip2gif\" "  
ae += "to save file \"HD:file.PICT\" \"r\""  
ExecuteScriptText/Z ae
```

On Macintosh, execute a Unix shell command:

exists

```
Function/S DemoUnixShellCommand()
// Paths must be POSIX paths (using /).
// Paths containing spaces or other nonstandard characters must be single-quoted.
// See Apple Technical Note TN2065 for more on shell scripting via AppleScript.
String unixCmd
unixCmd = "ls '/Applications/Igor Pro Folder'"

String igorCmd
sprintf igorCmd, "do shell script \"%s\"", unixCmd
Print igorCmd // For debugging only.

ExecuteScriptText igorCmd
Print S_value // For debugging only.
return S_value
End
```

On Windows, open MatLab in the background:

```
ExecuteScriptText/B "C:\\Matlab\\bin\\matlab.exe myFile.m"
```

On Windows, pass a script to Windows Script Host:

```
ExecuteScriptText/W=5 "WScript.exe \"C:\\Test Script.vbs\""
```

See Also

See **AppleScript** on page IV-188.

exists

exists(objNameStr)

The exists function returns a number which indicates if *objNameStr* contains the name of an Igor object, function or operation.

Details

objNameStr can optionally include a full or partial path to the object. If the name does not include a path, exists checks for waves, strings and variables in the current data folder.

The return values are:

- 0: Name not in use, or does not conflict with a wave, numeric variable or string variable in the specified data folder.
- 1: Name of a wave in the specified data folder.
- 2: Name of a numeric or string variable in the specified data folder.
- 3: Function name.
- 4: Operation name.
- 5: Macro name.
- 6: User-defined function name.

exists is not aware of local variables or parameters in user-defined functions, however it is aware of local variables and parameters in macros.

objNameStr is a string or string expression, *not* a name.

Examples

```
Print exists("veclen") // rather than exists(veclen)
```

Prints the following in the history area:

2

See Also

The **DataFolderExists** and **WaveExists** functions and the **WinType** operation.

exp

exp(num)

The exp function returns e^{num} . In complex expressions, *num* is complex, and **exp(num)** returns a complex value.

expInt

expInt(n, x)

The expInt function returns the value of the exponential integral $E_n(x)$:

$$E_n(x) = P \int_1^{\infty} \frac{e^{-xt}}{t^n} dt \quad x > 0; \quad n = 0, 1, 2, \dots$$

See Also

The **ei** function.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

expnoise

expnoise(b)

The expnoise function returns a pseudo-random value from an exponential distribution whose average and standard deviation are *b* and the probability distribution function is

$$f(x) = \frac{1}{b} \exp\left(-\frac{x}{b}\right).$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

SetRandomSeed; Chapter III-12, **Statistics** for a function and operation overview.

Extract

Extract [type flags] [/INDX/O] srcWave, destWave, LogicalExpression

The Extract operation finds data in *srcWave* wherever *LogicalExpression* evaluates to TRUE and stores the matching data sequentially in *destWave*, which will be created if it does not already exist.

Parameters

srcWave is the name of a wave.

destWave is the name of a new or existing wave that will contain the result.

LogicalExpression can use any comparison or logical operator in the expression.

Flags

/INDX Stores the index in *destWave* instead of data from *srcWave*.

/O Overwrites *destWave*.

Type Flags (used only in functions)

Extract also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Details

srcWave may be of any type including text.

destWave has the same type as *srcWave*, but it is always one dimensional. With /INDX, the *destWave* type is set to unsigned 32-bit integer and the values represent a linear index into *srcWave* regardless of its dimensionality.

Example

```
Make/O source= x
Extract/O source,dest,source>10 && source<20
print dest
```

Prints the following to the history area:

```
dest[0]= {11,12,13,14,15,16,17,18,19}
```

See Also

The **Duplicate** operation.

factorial

factorial(*n*)

The factorial function returns $n!$, where n is assumed to be a positive integer.

Note that while factorial is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over 2^{52} will be accurate to about one part in about 2×10^{16} . Values of n greater than 170 result in overflow and return Inf.

FakeData

FakeData(*waveName*)

The FakeData function puts fake data in the named wave, which must be single-precision float. This is useful for testing things that require changing data before you have the source for the eventual real data. FakeData can be useful in a background task expression.

The FakeData function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

Examples

```
Make/N=200 wave0; Display wave0
SetBackground FakeData(wave0)           // define background task
CtrlBackground period=60, start         // start background task
// observe the graph for a while
CtrlBackground stop                     // stop the background task
```

FastGaussTransform

FastGaussTransform [*flags*] *srcLocationsWave*, *srcWeightsWave*

The FastGaussTransform operation implements an efficient algorithm for evaluating the discrete Gauss transform, which is given by

$$G(y) = \sum_{i=1}^n q_i \exp \left[-\frac{\|y - x_i\|^2}{h} \right]$$

where G is an M-dimensional vector, y is an N-dimensional vector representing the observation position, $\{q_i\}$ are the M-dimensional weights, $\{x_i\}$ are N-dimensional vectors representing source locations, and h is the Gaussian width. The wave M_FGT contains the output in the current data folder.

Flags

/AERR= <i>aprxErr</i>	Sets the approximate error, which determines how many terms of the Taylor expansion of the Gaussian are used by the calculation. Default value is 1e-5.
/WDTH= <i>h</i>	Sets the Gaussian width. Default value is 1.
/OUTW= <i>locWave</i>	Specifies the locations at which the output is computed. <i>locWave</i> must have the same number of columns as <i>srcLocationsWave</i> . The other /OUT flags are mutually exclusive; you should use only one at any time.
/OUT1={ <i>x1,nx,x2</i> }	
/OUT2={ <i>x1,nx,x2,y1,ny,y2</i> }	
/OUT3={ <i>x1,nx,x2,y1,ny,y2,z1,nz,z2</i> }	Specifies gridded output of the required dimension. In each case you set the starting and ending values together with the number of intervals in that dimension. You cannot specify an output that does not match the dimensions of the input source.
/Q	No results printed in the history area.
/RX= <i>rx</i>	Sets the maximum radius of any cluster. The clustering algorithm terminates when the maximum radius is less than <i>rx</i> . Without /RX, the maximum radius is the same as the maximum radius encountered.
/RY= <i>ry</i>	Sets the upper bound for the distance between an observation point and a cluster center for which the cluster contributes to the transform value. Default is 5 <i>h</i> .
/TET= <i>nTerms</i>	Sets the number of terms in the Taylor expansion. Use /TET to set the number of terms and bypass the default error estimate, which is estimated from the approximate error value (/AERR).

/Z No error reporting.

Details

The discrete Gauss transform can be computed as a direct sum. An exact calculation is practical only for moderate number of sources and observation points and for low spatial dimensionality. With increasing dimensionality and increasing number of sources it is more efficient to take advantage of some properties of the Gaussian function. The FastGaussianTransform operation does so in two ways: It first arranges the sources in N-dimensional spatial clusters so that it is not necessary to compute the contributions of all source points that belong to remote clusters (see **FPClustering**). The second component of the algorithm is an approximation that factorizes the sum into a factor that depends only on source points and a factor that depends only on observation points. The factor that depends only on source points is computed only once while the factor that depends on observation points is evaluated once for each observation point.

The trade-off between computation efficiency and accuracy can be adjusted using multiple parameters. By default, the operation calculates the number of terms it needs to use in the Taylor expansion of the Gaussian. You can modify the default approximate error value using /AERR or you can directly set the number of terms in the expansion using /TET.

FastGaussianTransform supports calculations in dimensions that may exceed the maximum allowed wave dimensionality. *srcLocationsWave* must be a 2D, real-valued single- or double-precision wave in which each row corresponds to a single source position and columns represent the components in each dimension (e.g., a triplet wave would represent 3D source locations). *srcWeightsWave* must have the same number of rows as *srcLocationsWave* and it must be a real-valued single- or double-precision wave. In most applications *srcWeightsWave* will have a single column so that the output *G* will be scalar. However, if *srcWeightsWave* has multiple columns then *G* is a vector. This can be handy if you need to test multiple sets of coefficients at one time. If you specify observation points using /OUTW then *locWave* must have the same number of columns as *srcLocationsWave* (the number of rows in the output is arbitrary). The operation does not support wave scaling.

Yang, C., R. Duraiswami, and L. Davis, Efficient Kernel Machines Using the Improved Fast Gauss Transform, *Advances in Neural Information Processing Systems* 16, 2004.

FastOp

FastOp [/C] *destwave* = *prod1* [\pm *prod2* [\pm *prod3*]]

The FastOp operation can be used to get improved speed out of certain wave assignment statements. The syntax was designed so that you can simply insert FastOp in front of any wave assignment statement that meets the syntax requirements.

Parameters

<i>destWave</i>	An existing destination wave for the assignment expression. An error will be reported at runtime if the waves are not all the same length or number type.
<i>prod1, prod2, prod3</i>	Products with the following formats: $\text{constexpr} * \text{wave1} * \text{wave2}$ or $\text{constexpr} * \text{wave1} / \text{wave2}$ <i>constexpr</i> may be a literal numeric constant or a constant expression in parentheses. Such expressions are evaluated only once. Any component in a prod expression may be omitted.

Flags

/C Specifies a complex expression. Only applicable to floating point waves.

Details

Certain combinations are evaluated using faster specific code rather than more general but slower generic code. The following specific formats are given special consideration:

faverage

Single or Double Precision Real	Integer
$waved = C0$	$waved = C0$
$waved = C0 * waveA + C1$	$waved = waveA + C1$
$waved = waveA + C1$	$waved = waveA + waveB + C2$

In the above, pluses may be minuses and the trailing constant ($C0$, $C1$, $C2$) may be omitted.

Note: Integer waves are evaluated using double precision intermediate values except for the aforementioned special cases which are evaluated using the native format.

Typically, FastOp will improve performance by 10 to 40 times. The speed increase will be dependent on the computer and on the length of the waves, with the greatest improvement for waves having 1000 to 100,000 points.

This operation replaces the obsolete FastWaveOps XOP. It has all the capabilities of the XOP and then some and has an easier to read syntax.

Examples

Valid expressions:

```
FastOp waved= 3
FastOp waved= waveA + waveB
FastOp waved= 0.5*waveA + 0.5*waveB
FastOp waved= waveA*waveB
FastOp waved= (2*3)*waveA + 6
FastOp waved= (locvar)*waveA
```

Expressions that are **not** valid:

```
FastOp waved= 3*4
FastOp waved= (waveA + waveB)
FastOp waved= waveA*0.5 + 0.5*waveB
FastOp waved= waveA*waveB/2
FastOp waved= 2*3*waveA + 6
FastOp waved= locvar*waveA
```

See Also

The **MatrixOP** operation for more efficient matrix operations.

faverage

faverage(*waveName* [, *x1*, *x2*])

The faverage function returns the trapezoidal average value of the named wave from $x=x1$ to $x=x2$.

If your data are in the form of an XY pair of waves, see **faverageXY**.

Details

If $x1$ and $x2$ are not specified, they default to $-\infty$ and $+\infty$, respectively.

If $x1$ or $x2$ are not within the X range of *waveName*, faverage limits them to the nearest X range limit of *waveName*.

faverage returns the area divided by $(x2-x1)$. In other words, the X scaling of *waveName* is eliminated when computing the average.

If any Y values in the specified X range are NaN, faverage returns NaN.

Unlike the **area** function, reversing the order of $x1$ and $x2$ does *not* change the sign of the returned value.

The faverage function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

Examples

Comparison of area, faverage and mean functions over interval (12.75,13.32)

```
area(wave,12.75,13.32) = 0.05 * (43+55) / 2 // first trapezoid
                      + 0.20 * (55+88) / 2 // second trapezoid
                      + 0.20 * (88+100) / 2 // third trapezoid
                      + 0.12 * (100+92.2) / 2 // fourth trapezoid
                      = 47.082
```

```
faverage(wave,12.75,13.32) = area(wave,12.7,13.32) / (13.32-12.75)
                          = 47.082 / 0.57 = 82.6
```

```
mean(wave,12.75,13.32) = (55+88+100+87) / 4 = 82.5
```

See Also

Integrate operation and **area** function.

faverageXY

faverageXY(*XWaveName*, *YWaveName* [, *x1*, *x2*])

The **faverageXY** function returns the trapezoidal average value of *YWaveName* from $x=x1$ to $x=x2$, using *X* values from *XWaveName*.

This function operates identically to **faverage**, except that it uses an *XY* pair of waves for *X* and *Y* values.

Details

If *x1* and *x2* are not specified, they default to $-\infty$ and $+\infty$, respectively.

If *x1* or *x2* are not within the *X* range of *XWaveName*, **faverageXY** limits them to the nearest *X* range limit of *XWaveName*.

faverageXY returns the area divided by $(x2 - x1)$.

If any values in the *X* range are NaN, **faverageXY** returns NaN.

Reversing the order of *x1* and *x2* does not change the sign of the returned value.

The values in *XWaveName* may be increasing or decreasing. **faverageXY** assumes that the values in *XWaveName* are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any *X* values are NaN, the result is NaN.

The **faverageXY** function is not multidimensional aware. See Chapter II-6, **Multidimensional Waves** for details on multidimensional waves, particularly **Analysis on Multidimensional Waves** on page II-94.

See Also

See **faverage**, **areaXY**, **area**, and **PolygonArea**.

FBinRead

FBinRead [*flags*] *refNum*, *objectName*

The **FBinRead** operation reads binary data from the file specified by *refNum* into the named object.

Parameters

refNum is a file reference number from the Open operation used to open the file.

objectName is the name of a wave, numeric variable, string variable, or structure.

Flags

/B[=*b*] Specifies file byte ordering.

	<i>b</i> =0:	Native (same as no /B).
	<i>b</i> =1:	Reversed (same as /B for compatibility with Igor Pro 3.0).
	<i>b</i> =2:	Big-endian (Motorola/Macintosh).
	<i>b</i> =3:	Little-endian (Intel/Windows).
/F= <i>f</i>		Controls the number of bytes read and how the bytes are interpreted.
	<i>f</i> =0:	Native binary format of the object (default).
	<i>f</i> =1:	Signed one-byte integer.
	<i>f</i> =2:	Signed 16-bit word; two bytes.
	<i>f</i> =3:	Signed 32-bit word; four bytes.
	<i>f</i> =4:	32-bit IEEE floating point.
	<i>f</i> =5:	64-bit IEEE floating point.
	<i>f</i> =6:	80-bit SANE Extended (<i>Macintosh only</i> ; returns NaN on Windows).
	<i>f</i> =7:	96-bit Motorola Extended (<i>Macintosh only</i> ; returns NaN on Windows).
/U		Integer formats (/F=1, 2, or 3) are unsigned. If /U is missing, integers are signed.

Details

If *objectName* is the name of a string variable then /F doesn't apply. The number of bytes read is the number of bytes in the string *before* the FBinRead operation is called. You can use the **PadString** function to set the size of a string.

The binary format that FBinRead uses for numeric variables or waves depends on the /F flag. If no /F flag is present, the native binary format of the named object is used.

Byte ordering refers to the order in which a multibyte datum is read from a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is read from the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is read from the file first.

FBinRead will read an entire structure from a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinRead operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **Open** operation. See **FSetPos** to set positions within files and **FStatus** for file information.

FBinWrite

FBinWrite [*flags*] *refNum*, *objectName*

The FBinWrite operation writes the named object in binary to a file.

Parameters

refNum is a file reference number from the **Open** operation used to open the file.

objectName is the name of a wave, numeric variable, string variable, or structure.

Flags

/B[= <i>b</i>]	Specifies file byte ordering.
	<i>b</i> =0: Native (same as no /B).
	<i>b</i> =1: Reversed (same as /B for compatibility with Igor Pro 3.0).
	<i>b</i> =2: Big-endian (Motorola/Macintosh).
	<i>b</i> =3: Little-endian (Intel/Windows).
/F= <i>f</i>	Controls the number of bytes written and how the bytes are formatted.
	<i>f</i> =0: Native binary format of the object (default).
	<i>f</i> =1: Signed byte; one byte.
	<i>f</i> =2: Signed 16-bit word; two bytes.
	<i>f</i> =3: Signed 32-bit word; four bytes.
	<i>f</i> =4: 32-bit IEEE floating point.

- f*=5: 64-bit IEEE floating point.
f=6: 80-bit SANE Extended (*Macintosh only*).
f=7: 96-bit Motorola Extended (*Macintosh only*).
 /P Adds an IgorBinPacket to the data. This is used for PPC or Apple event result packets (*refNum* = 0) and is not normally of use when writing to a file.
 /U Integer formats (/F=1, 2, or 3) are unsigned. If /U is missing, integers are signed.

Details

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC) or Apple events (*Macintosh*) or DDE (*Windows*). The data that would normally be written to a file is appended to the PPC or Apple event or DDE result packet.

If the object is a string variable then /F doesn't apply. The number of bytes written is the number of bytes in the string.

The binary format that FBinWrite uses for numeric variables or waves depends on the /F flag. If no /F flag is present, FBinWrite uses the native binary format of the named object.

Byte ordering refers to the order in which a multibyte datum is written to a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is written to the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is written to the file first.

FBinWrite will write an entire structure to a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinWrite operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

The **Open** operation and Chapter IV-10, **Advanced Programming**. See **FSetPos** to set positions within files and **FStatus** for file information.

FFT

FFT [*flags*] *srcWave*

The FFT operation computes the Discrete Fourier Transform of *srcWave* using a multidimensional prime factor decomposition algorithm. By default, *srcWave* is overwritten by the FFT.

The FFT operation has been extensively revised for Igor Pro 5; see **Details** for backwards compatibility information.

Flags

- /COLS Computes the 1D FFT of 2D *srcWave* one column at a time, storing the results in the destination wave.

$$I[t_1][n] = \sum_{k=0}^{N-1} f[t_1][k] e^{i2\pi kn/N}.$$

You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of rows must be even. If *srcWave* is a real (N×M) wave, the output matrix will be (1+N/2,M) in analogy with 1D FFT. To avoid changes in the number of points you can convert *srcWave* to complex data type. This flag applies only to 2D source waves. See also the /ROWS flag.

- /DEST=*destWave* Saves FFT results in the current data folder only if you do not specify an output wave and you are using one or more flags (except for /Z). The default wave name is W_FFT for a 1D FFT and M_FFT for multidimensional FFT.

When used in a function, the FFT operation by default creates a complex wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-53 for details.

- /HCC Hypercomplex transform (cosine). Computes the integral

$$I_c(w_1, w_2) = \iint_{-\infty}^{\infty} f(t_1, t_2) \cos(t_1 w_1) e^{it_2 w_2} dt_1 dt_2$$

	using the 2D FFT (see Details).
/HCS	Hypercomplex transform (sine). Computes the integral $I_3(w_1, w_2) = \iint_{-\infty}^{\infty} f(t_1, t_2) \sin(t_1 w_1) e^{it_2 w_2} dt_1 dt_2$
	using the 2D FFT (see Details).
/MAG	Saves just the magnitude of the FFT in the output wave. See comments under /OUT.
/MAGS	Saves the squared magnitude of the FFT in the output wave. See comments under /OUT.
/OUT= <i>mode</i>	Sets the output wave format. <i>mode</i> =1: Default for complex output. <i>mode</i> =2: Real output. <i>mode</i> =3: Magnitude. <i>mode</i> =4: Magnitude square. <i>mode</i> =5: Phase. You can also identify modes 2-4 using the convenience flags /REAL, /MAG, and /MAGS. The convenience flags are mutually exclusive and are overridden by the /OUT flag.
/PAD={ <i>dim1</i> [, <i>dim2</i> , <i>dim3</i> , <i>dim4</i>]}	Converts <i>srcWave</i> into a padded wave of dimensions <i>dim1</i> , <i>dim2</i> The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The <i>dim1</i> ... values must be greater than or equal to the corresponding dimension size of <i>srcWave</i> . If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, /Pad= <i>dim1</i> will set <i>dim2</i> and above to match the dimensions in <i>srcWave</i> .
/REAL	Saves just the real part of the transform in the output wave. See comments under /OUT.
/ROWS	Calculates the FFT of only the first dimension of a 2D <i>srcWave</i> . It thus computes the 1D FFT of one row at a time, storing the results in the destination wave.
	$N[n][t_2] = \sum_{k=0}^{N-1} f[n][t_2] e^{i2\pi kn} \square^N.$ <p>You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of columns must be even. If <i>srcWave</i> is a real (N×M) wave, the output matrix will be (N,1+M/2) in analogy with 1D FFT. To avoid changes in the number of points you can convert <i>srcWave</i> to complex data type. See also /COLS flag.</p>
/RP=[<i>startPoint</i> , <i>endPoint</i>]	
/RX=(<i>startX</i> , <i>endX</i>)	Defines a segment of a 1D <i>srcWave</i> that will be transformed. By default the operation transforms the whole wave. It is sometimes useful to take advantage of this feature in order to transform just the defined interval, which includes both end points. You can define the interval using wave point indexing with the /RP flag or using the X-values with the /RX flag. The interval must include at least four data points and the total number of points must be an even number.
/WINF= <i>windowKind</i>	Premultiplies a 1D <i>srcWave</i> with the selected window function. In the following window definitions, <i>w(n)</i> is the value of the window function that multiplies the signal, <i>N</i> is the number of points in the signal wave (or range if /R is specified), and <i>n</i> is the wave point index. With /R, <i>n</i> =0 for the first datum in the range. Choices for <i>windowKind</i> are in bold (some windows, in italics, have multiple options for different constant values): Bartlett: a synonym for Bartlett. Bartlett: $w(n) = \begin{cases} \frac{n}{N \square} & n = 0, 1, \square, \frac{N}{2} \\ W(N-n) & n = \frac{N}{2}, \square, N-1 \end{cases}.$

Blackman: $w(n) = a_0 - a_1 \cos\left(\frac{2\pi}{N}n\right) + a_2 \cos\left(\frac{2\pi}{N}2n\right) - a_3 \cos\left(\frac{2\pi}{N}3n\right) \quad .$
 $n = 0, 1, 2, \dots, N-1$

<i>windowKind</i>	a_0	a_1	a_2	a_3
Blackman367	0.42323	0.49755	0.07922	
Blackman361	0.44959	0.49364	0.05677	
Blackman492	0.35875	0.48829	0.14128	0.01168
Blackman474	0.40217	0.49703	0.09392	0.00183

Cos: $w(n) = \cos\left(\frac{n}{N}\pi\right)^\alpha \quad n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2}.$

Cos1: $\alpha = 1.$

Cos2: $\alpha = 2.$

Cos3: $\alpha = 3.$

Cos4: $\alpha = 4.$

Hamming: $w(n) = \begin{cases} 0.54 + 0.46 \cos\left(\frac{2\pi}{N}n\right) & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ 0.54 - 0.46 \cos\left(\frac{2\pi}{N}n\right) & n = 0, 1, 2, \dots, N-1 \end{cases}.$

Hanning: $w(n) = \begin{cases} \frac{1}{2} \left[1 + \cos\left(\frac{2n}{N}\pi\right) \right] & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ \frac{1}{2} \left[1 - \cos\left(\frac{2n}{N}\pi\right) \right] & n = 0, 1, 2, \dots, N-1 \end{cases}.$

Kaiser Bessel: $w(n) = \frac{I_0\left(\pi\alpha \sqrt{1 - \left(\frac{n}{N/2}\right)^2}\right)}{I_0(\pi\alpha)} \quad 0 \leq |n| \leq \frac{N}{2}.$

$$I_0(X) = \sum_{k=0}^{\infty} \left(\frac{(X/2)^{2k}}{k!} \right)^2$$

KaiserBessel20: $\alpha = 2.$

KaiserBessel25: $\alpha = 2.5.$

KaiserBessel30: $\alpha = 3.$

Parzen: $w(n) = 1 - \left| \frac{n}{N/2} \right|^2 \quad 0 \leq |n| \leq \frac{N}{2}.$

Poisson: $w(n) = \exp\left(-\alpha \frac{|n|}{N/2}\right) \quad 0 \leq |n| \leq \frac{N}{2}.$

Poisson2: $\alpha = 2.$

Poisson3: $\alpha = 3.$

Poisson4: $\alpha = 4.$

Riemann: $w(n) = \frac{\sin\left(\frac{n}{N}2\pi\right)}{\left(\frac{n}{N}2\pi\right)} \quad 0 \leq |n| \leq \frac{N}{2}.$

/Z

Disables rotation of the FFT of a complex wave. Igor normally rotates the FFT result (which is also complex) by $N/2$ so that $x=0$ is at the center point ($N/2$). When /Z is specified, Igor does not perform this rotation and leaves $x=0$ at the first point (0).

Details

The data type of *srcWave* is arbitrary. The first dimension of *srcWave* must be an even number and the minimum length of *srcWave* is four points. When *srcWave* is a double precision wave, the FFT is computed in double precision. All other data types are transformed using single precision calculations. The result of the FFT operation is always a floating point number (single or double precision).

Depending on your choice of outputs, you may not be able to invert the transform in order to obtain the original *srcWave*.

srcWave or any of its intervals must have at least four data points and must not contain NaNs or INFs.

The FFT algorithm is based on prime number decomposition, which decomposes the number of points in each dimension of the wave into a product of prime numbers. The FFT is optimized for primes < 5. In time consuming applications it is frequently worthwhile to pad the data so that the total number of points factors into small prime numbers.

All the changes to this operation preserve compatibility with earlier versions of Igor Pro.

The hypercomplex transforms are computed by writing the sine and cosine as a sum of two exponentials. Let the 2D Fourier transform of the input signal be

$$F[n_1][n_2] = \sum_{k_1=0}^{N_1-1} \sum_{k_2=0}^{N_2-1} f[k_1][k_2] \exp\{i2\pi k_1 n_1 / N_1 + i2\pi k_2 n_2 / N_2\}$$

then the two hypercomplex transforms are given by

$$I_c[n_1][n_2] = \frac{1}{2}\{F[n_1][n_2] + F[-n_1][n_2]\} \quad \text{and} \quad I_s[n_1][n_2] = \frac{1}{2i}\{F[n_1][n_2] - F[-n_1][n_2]\}.$$

FIFO2Wave

FIFO2Wave [/R/S] *FIFOName*, *channelName*, *waveName*

The FIFO2Wave operation copies FIFO data from the specified channel of the named FIFO into the named wave. FIFOs are used for data acquisition.

Flags

/R=[startPoint,endPoint]	Dumps the specified FIFO points into the wave.
/S=s	s=0: Same as no /S.
	s=1: Sets the wave's X scaling x0 value to the number of the first sample in the FIFO.
	s=2: Changes the wave's number type to match the FIFO channel's type.
	s=3: Combination of s=1 and s=2.

Details

The FIFO must be in the valid state for FIFO2Wave to work. When you create a FIFO, using NewFIFO, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

If you specify a range of FIFO data points, using `/R=[startPoint,endPoint]` then FIFO2Wave dumps the specified FIFO points into the wave after clipping *startPoint* and *endPoint* to valid point numbers.

The valid point numbers depend on whether the FIFO is running and on whether or not it is attached to a file. If the FIFO is running then *startPoint* and *endPoint* are truncated to number of points in the FIFO. If the FIFO is buffering a file then the range can include the full extent of the file.

If you specify no range then FIFO2Wave transfers the most recently acquired FIFO data to the wave. The number of points transferred is the smaller of the number of points in the FIFO and number of points in the wave.

FIFO2Wave may or may not change the wave's X scaling and number type, depending on the current X scaling and on the `/S` flag.

Think of the wave's X scaling as being controlled by two values, x_0 and Δx , where the X value of point p is $x_0 + p \cdot \Delta x$. FIFO2Wave always sets the wave's Δx value equal to the FIFO's `deltaT` value (as set by the `CtrlFIFO` operation). If you use no `/S` flag, FIFO2Wave does not set the wave's x_0 value nor does it set the wave's number type.

If you are using FIFO2Wave to update a wave in a graph as quickly as possible, the `/S=0` flag gives the highest update rate. The other `/S` values trigger more recalculation and slow down the updating.

If the wave's number type (possibly changed to match the FIFO channel) is a floating point type, FIFO2Wave scales the FIFO data before transferring it to the wave as follows:

`scaled_value = (FIFO_value - offset) * gain`

If the FIFO channel's gain is one and its offset is zero, the scaling would have no effect so FIFO2Wave skips it.

If the specified FIFO channel is an image strip channel (one defined using the optional `vectPnts` parameter to `NewFIFOChan`), then the resultant wave will be a matrix with the number of rows set by `vectPnts` and the number of columns set by the number of points described above for one-dimensional waves. To create an image plot that looks the same as the corresponding channel in a Chart, you will need to transpose the wave using **MatrixTranspose**.

See Also

The **NewFIFO** and **CtrlFIFO** operations, and **FIFOs and Charts** on page IV-208 for more information on FIFOs and data acquisition. For an explanation of waves and wave scaling, see **Changing Dimension and Data Scaling** on page II-70.

FIFOStatus

FIFOStatus [`/Q`] *FIFOName*

The **FIFOStatus** operation returns miscellaneous information about a FIFO and its channels. FIFOs are used for data acquisition.

Flags

`/Q` Doesn't print in the history area.

Details

FIFOStatus sets the variable `V_flag` to nonzero if a FIFO of the given name exists. If the named FIFO does exist then **FIFOStatus** stores information about the FIFO in the following variables:

`V_FIFORunning` Nonzero if FIFO is running.
`V_FIFOChunks` Number of chunks of data placed in FIFO so far.
`V_FIFOonchans` Number of channels in the FIFO.
`S_Info` Keyword-packed information string.

The keyword-packed information string consists of a sequence of sections with the following form: *keyword:value*;

You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the keywords for `S_Info`:

Keyword	Type	Meaning
DATE	Number	The date/time when start was issued via <code>CtrlFIFO</code> .
DELTAT	Number	The FIFO's <code>deltaT</code> value as set by <code>CtrlFIFO</code> .
DISKTOT	Number	Current number of chunks written to the FIFO's file.

FilterFIR

Keyword	Type	Meaning
FILENUM	Number	The output file refNum or review file refNum as set by CtrlFIFO. This will be zero if the FIFO is connected to no file.
NOTE	String	The FIFO's note string as set by CtrlFIFO.
VALID	Number	Zero if FIFO is not valid.

In addition, FIFOStatus writes fields to S_Info for each channel in the FIFO. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the S_Info string: NAME4:Pressure.

In the following table, the channel's number is represented by "#".

Keyword	Type	Meaning
FSMINUS#	Number	Channel's minus full scale value as set by NewFIFOChan.
FSPLUS#	Number	Channel's plus full scale value as set by NewFIFOChan.
GAIN#	Number	Channel's gain value as set by NewFIFOChan.
NAME#	String	Name of channel.
OFFSET#	Number	Channel's offset value as set by NewFIFOChan.
UNITS#	String	Channel's units as set by NewFIFOChan.

See Also

The **NumberByKey** and **StringByKey** functions for parsing keyword-value strings.

FilterFIR

FilterFIR [*flags*] *waveName* [, *waveName*]...

The FilterFIR operation convolves each *waveName* with automatically-designed filter coefficients or with *coefsWaveName* using time-domain methods.

The automatically-designed filter coefficients are simple lowpass and highpass window-based filters or a maximally-flat notch filter. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

FilterFIR filters data faster than **Convolve** when there are many fewer filter coefficient values than data points in *waveName*.

Note: FilterFIR replaces the obsolete **SmoothCustom** operation.

Parameters

waveName is a destination wave that is overwritten by the convolution of itself and the filter.

waveName may be multidimensional, but only one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

Flags

/COEF [=coefsWaveName]

Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of convolving *waveName* with coefficients in *coefsWaveName*.

coefsWaveName must not be one of the destination *waveNames*. It must be single- or double-precision numeric and one-dimensional.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the "center" coefficient in the middle of the wave.

The coefficients are usually symmetrical about the middle point, but FilterFIR does not enforce this.

<code>/DIM=<i>d</i></code>	<p>Specifies the wave dimension to filter.</p> <p><i>d</i>=-1: Treats entire wave as 1D (default).</p> <p>For <i>d</i>=0, 1,..., operates along rows, columns, etc.</p> <p>Use <code>/DIM=0</code> to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional <i>waveName</i> where each row comprises all of the sound samples at a particular time.</p>
<code>/E=<i>endEffect</i></code>	<p>Determines how the ends of the wave (<i>w</i>) are handled when fabricating missing neighbor values. <i>endEffect</i> has values:</p> <ul style="list-style-type: none"> 0: Bounce method (default). Uses <i>w</i>[<i>i</i>] in place of the missing <i>w</i>[-<i>i</i>] and <i>w</i>[<i>n-i</i>] in place of the missing <i>w</i>[<i>n+i</i>]. 1: Wrap method. Uses <i>w</i>[<i>n-i</i>] in place of the missing <i>w</i>[-<i>i</i>] and vice versa. 2: Zero method. Uses 0 for any missing value. 3: Fill method. Uses <i>w</i>[0] in place of the missing <i>w</i>[-<i>i</i>] and <i>w</i>[<i>n</i>] in place of the missing <i>w</i>[<i>n+i</i>].
<code>/HI={<i>f1</i>, <i>f2</i>, <i>n</i>}</code>	<p>Creates a high-pass filter based on the windowing method, using the Hanning window unless another window is specified by <code>/WINF</code>.</p> <p><i>f1</i> and <i>f2</i> are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).</p> <p><i>f1</i> is the end of the reject band, and <i>f2</i> is the start of the pass band:</p> $0 < f1 < f2 < 0.5$ <p><i>n</i> is the number of FIR filter coefficients to generate. A larger number gives better stop-band rejection. A good number to start with is 101.</p> <p>Use both <code>/HI</code> and <code>/LO</code> to create a bandpass filter.</p>
<code>/LO={<i>f1</i>, <i>f2</i>, <i>n</i>}</code>	<p>Creates a low-pass filter. <i>f1</i> is the end of the pass band, <i>f2</i> is the start of the reject band, and <i>n</i> is the number of FIR filter coefficients. See <code>/HI</code> for more details.</p>
<code>/NMF={<i>fc</i>, <i>fw</i> [, <i>eps</i>, <i>nMult</i>]}</code>	<p>Creates a maximally-flat notch filter centered at <i>fc</i> with a -3dB width of <i>fw</i>. <i>fc</i> and <i>fw</i> are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).</p> <p>The longest filter length allowed is 4001 points, which requires <i>fw</i> ≥ 0.0079 (1.58% of the sampling frequency).</p> <p>Coefficients at the ends that are smaller than the optional <i>eps</i> parameter are removed, making the filter shorter (and faster), though less accurate. The default is 2^{-40}. Use 0 to retain all coefficients, no matter how small, even zero coefficients.</p> <p><i>nMult</i> specifies how much longer the filter may be to obtain the most accurate notch frequency. The default is 2 (potentially twice as many coefficients). Set <i>nMult</i> ≤ 1 to generate the shortest possible filter.</p> <p>The maximally flat notch filter design is based on Zahradník and Vlcek, and uses arbitrary precision math (see APMath) to compute the coefficients.</p>
<code>/WINF=<i>windowKind</i></code>	<p>Applies the named “window” to the filter coefficients. Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when many filter coefficients are used.</p> <p>If <code>/WINF</code> is not specified, the Hanning window is used. For no coefficient filtering, use <code>/WINF=None</code>.</p> <p>Choices for <i>windowKind</i> are (see the FFT <code>/WINF</code> flag for window equations and details): Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.</p>

Details

If *coefsWaveName* is specified, then `/HI`, `/LO`, and `/NMF` are ignored.

If more than one of /HI, /LO, and /NMF are specified, the filters are combined using linear convolution. The length of the combined filter is slightly less than the sum of the individual filter lengths.

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length should be small in comparison to the destination waves.

FilterFIR assumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The “middle” point number = $\text{trunc}(\text{numpts}(\text{coefsWaveName} - 1)/2)$. *coefsWaveName* usually contains the two-sided impulse response of a filter, and usually contains an odd number of points. This is the kind of coefficients data generated by /HI, /LO, and /NMF.

FilterFIR ignores the X scaling of all waves, except when /COEF creates a coefficients wave, which preserves the X scale deltax and alters the leftx value so that the zero-phase (center) coefficient is located at $x=0$.

Examples

```
// Make test sound from three sine waves

FilterIIR

FilterIIR [*flags*] [*waveName*,...]

The FilterIIR operation applies to each *waveName* either the automatically-designed IIR filter coefficients or the IIR filter coefficients in *coefsWaveName*. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

The automatically-designed filter coefficients are bilinear transforms of the Butterworth analog prototype with an optional variable-width notch filter.

To design more advanced IIR filters, see **Designing the IIR Coefficients**.

Parameters

waveName may be multidimensional, but only the one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

waveName may be omitted for the purpose of checking the format of *coefsWaveName*. If the format is detectably incorrect an error code will be returned in V_flag. Use /Z to prevent command execution from stopping.

Filtering of segmented data is supported through use of the /STAT flag.

Flags

- | | |
|------------------------|---|
| /CASC | Specifies that <i>coefsWaveName</i> contains cascaded bi-quad filter coefficients. The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form 1 filtering. See Cascade Details . |
| /COEF [=coefsWaveName] | Replaces the first output <i>waveName</i> by the filter coefficients instead of the filtered results or, when <i>coefsWaveName</i> is specified, replaces the output wave(s) by the result of filtering <i>waveName</i> with the IIR coefficients in <i>coefsWaveName</i> .
<i>coefsWaveName</i> must not be one of the destination <i>waveNames</i> . It must be single- or double-precision numeric and two-dimensional.
When used with /CASC, <i>coefsWaveName</i> must have 6 columns, containing real-valued coefficients for a product of ratios of second-order polynomials (cascaded bi-quad sections).
If /ZP is specified, it must be complex, otherwise it must be real.
See Details for the format of the coefficients in <i>coefsWaveName</i> . |
| /DIM= <i>d</i> | Specifies the wave dimension to filter.
<i>d</i> =-1: Treats entire wave as 1D (default).
For <i>d</i> =0, 1,..., operates along rows, columns, etc.
Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional <i>waveName</i> where each row comprises all of the sound samples at a particular time. |
| /HI= <i>fHigh</i> | Creates a high-pass Butterworth filter with the -3dB corner at <i>fHigh</i> . The order of the filter is controlled by the /ORD flag.
<i>fHigh</i> is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency). |

/LO= <i>fLow</i>	Creates a low-pass Butterworth filter with the -3dB corner at <i>fLow</i> . The /ORD flag controls the order of the filter. <i>fLow</i> is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency). Create bandpass and bandreject filters by specifying both /HI and /LO. For a bandpass filter, set <i>fLow</i> > <i>fHigh</i> , and for a band reject filter, set <i>fLow</i> < <i>fHigh</i> .
/N={ <i>fNotch</i> , <i>notchQ</i> }	Creates a notch filter with the center frequency at <i>fNotch</i> and a -3dB width of <i>fNotch</i> / <i>notchQ</i> . <i>fNotch</i> is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency). <i>notchQ</i> is a number greater than 1, typically 10 to 100. Large values produce a filter that "rings" a lot.
/ORD= <i>order</i>	Sets the order of the Butterworth filter(s) created by /HI and /LO. The default is 2 (second order), and the maximum is 100.
/Z= <i>z</i>	Prevents procedure execution from aborting when an error occurs. Use /Z=1 to handle this case in your procedures using GetRTErr (1) rather than having execution abort. /Z=0 is the same as no /Z at all.
/ZP	Specifies that <i>coefsWaveName</i> contains complex z-domain zeros (in column 0) and poles (in column 1) or, if <i>coefsWaveName</i> is not specified, that the first output <i>waveName</i> is to be replaced by filter coefficients in the zero-pole format. See Zeros and Poles Details .

Details

FilterIIR sets V_flag to 0 on success or to an error code if an error occurred. Command execution stops if an error occurs unless the /Z flag is set. Omit /Z and call **GetRTErr** and **GetRTErrMessage** under similar circumstances to see what the error code means.

Direct Form 1 Details

Unless /CASC or /ZP are specified, the coefficients in *coefsWaveName* describe a ratio of two polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{a_0 + a_1 z^{-1} + a_2 z^{-2} + \dots}{b_0 + b_1 z^{-1} + b_2 z^{-2} + \dots}$$

Direct Form I Implementation

$$y_i = \frac{a_0 x_i + a_1 x_{i-1} + a_2 x_{i-2} + \dots - b_1 y_{i-1} - b_2 y_{i-2} + \dots}{b_0}$$

where *x* is the input wave *waveName* and *y* is the output wave (either *waveName* again or *destWaveName*).

FilterIIR computes the filtered result using the Direct Form I implementation of *H(z)*.

The rational polynomial numerator (*a_i*) coefficients in are column 0 and denominator (*b_i*) coefficients in column 1 of *coefsWaveName*.

The coefficients in row 0 are the nondelayed coefficients *a₀* (in column 0) and *b₀* (in column 1).

The coefficients in row 1 are the z^{-1} coefficients, a_1 and b_1 .

The coefficients in row n are the z^{-n} coefficients, a_n and b_n .

The number of coefficients for the numerator can differ from the number of coefficients for the denominator. In this case, specify 0 for unused coefficients.

Note: If all the coefficients of the denominator are 0 ($b_i = 0$ except $b_0 = 1$), then the filter is actually a causal FIR filter (Finite Impulse Response filter with delay of $n-1$). In this sense, FilterIIR implements a superset of the FilterFIR operation.

Alternate Direct Form 1 Notation

The designation of a_i , etc. as the numerator is at odds with many textbooks such as *Digital Signal Processing*, which uses b for the numerator coefficients of the rational function, a for the denominator coefficients with an implicit $a_0 = 1$, in addition to reversing the signs of the remaining denominator coefficients so that they can write $H(z)$ as:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{i=0}^n b_i z^{-i}}{1 - \sum_{i=1}^n a_i z^{-i}}.$$

Coefficients derived using this notation need their denominator coefficients sign-reversed before putting them into rows 1 through n of column 1 (the second column), and the “missing” nondelayed denominator coefficient of 1.0 placed in row 0, column 1.

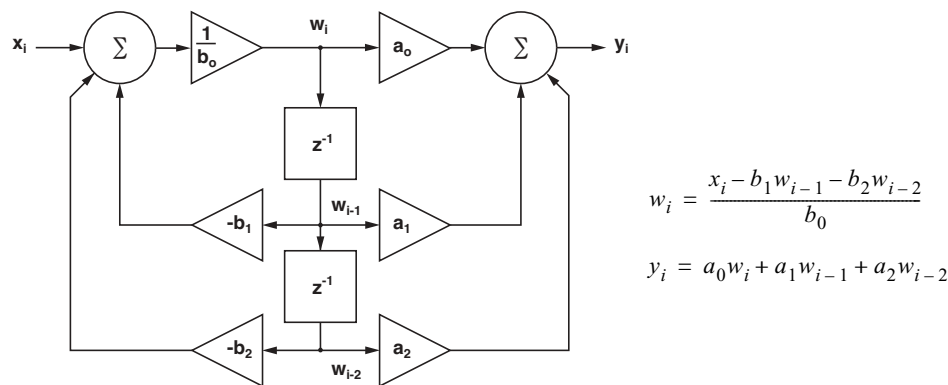

Cascade Details

When using /CASC, coefficients in *coefsWaveName* describe the product of one or more ratios of two quadratic polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \prod_{k=1}^k \frac{a_{0_k} + a_{1_k} z^{-1} + a_{2_k} z^{-2}}{b_{0_k} + b_{1_k} z^{-1} + b_{2_k} z^{-2}}.$$

Each product term implements a “cascaded bi-quad section”, and $H(z)$ can be realized by feeding the output of one section to the next one.

The cascade coefficients filter the data using a Direct Form II cascade implementation:

Cascaded Bi-Quad Direct Form II Implementation

The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form I filtering. Cascade IIR filtering is recommended when the filter order exceeds 16 (a 16th-order Direct Form I filter has 17 numerator coefficients and 17 denominator coefficients).

coefsWaveName must be a six-column real-valued numeric wave. Each row describes one bi-quad section. The coefficients for the second term (or “section”) of the product ($k=2$) are in the following row, etc.:

<i>k</i>	Row	Col 0	Col 1	Col 2	Col 3	Col 4	Col 5
1	0	a_{0_1}	a_{1_1}	a_{2_1}	b_{0_1}	b_{1_1}	b_{2_1}
2	1	a_{0_2}	a_{1_2}	a_{2_2}	b_{0_2}	b_{1_2}	b_{2_2}
...							

The number of coefficients for the numerator (a ’s) is allowed to differ from the number of coefficients for the denominator (b ’s). In this case, specify 0 for unused coefficients.

For example, a third order filter (three poles and three zeros) cascade implementation is a single-order section combined with a second order section. The values for a_{2_k} , b_{2_k} for that section (k) would be 0. Here the second section is specified as the first-order section:

<i>k</i>	Row	Col 0	Col 1	Col 2	Col 3	Col 4	Col 5
1	0	a_{0_1}	a_{1_1}	a_{2_1}	b_{0_1}	b_{1_1}	b_{2_1}
2	1	a_{0_2}	a_{1_2}	0	b_{0_2}	b_{1_2}	0

Alternate Cascade Notation

In the DSP literature, the b_{0_k} gain values are typically one and the $H(z)$ expression contains an overall gain value, usually K . Here each product term (or “section”) has a user-settable gain value. Computing the correct gain values to control overflow in integer implementations is the responsibility of the user. For floating implementations, you might as well set all b_{0_k} values to one except, say, b_{0_1} , to control the overall gain.

Zeros and Poles Details

When using /ZP, coefficients in *coefsWaveName* contains complex zeros and poles in the (also complex) Z transform domain:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{(z - z_0) \propto (z - z_1) \propto (z - z_2) \propto \dots}{(z - p_0) \propto (z - p_1) \propto (z - p_2) \propto \dots}.$$

coefsWaveName must be a two-column complex wave with zero0, zero1,... zeroN in the first column of N+1 rows, and pole0, pole1,... poleN in the second column of those same rows:

<i>k</i>	Row	Col 0	Col 1
1	0	(zero0Real, zero0Imag)	(pole0Real, pole0Imag)
2	1	(zero1Real, zero1Imag)	(pole1Real, pole1Imag)
3	2	(zero2Real, zero2Imag)	(pole2Real, pole2Imag)
...			

If a zero or pole has a nonzero imaginary component, the conjugate zero or pole must be included in *coefsWaveName*. For example, if a zero is placed at (0.7, 0.5), the conjugate is (0.7, -0.5), and that value must also appear in column 0. These two zeros form what is known as a “conjugate pair”. The conjugate values must match within the greater of 1.0e-6 or $1.0e-6 * |zeroOrPole|$.

Use (0,0) for unused poles or zeros, as a zero or pole at $z = (0,0)$ has no effect on the filter frequency response.

The /ZP format for the coefficients is internally converted into the Direct Form 1 implementation, or into the Cascade Direct Form 2 implementation if /CASC is specified. There is no option for returning these implementation-dependent coefficients in a wave.

Designing the IIR Coefficients

Simple IIR filters can be used or created by specifying the /LO, /HI, /ORD, /N, /CASC, and /ZP flags. Use /COEF without *coefsWaveName* to put these simple IIR filter coefficients into the first *waveName*.

More advanced IIR filters (Bessel, Chebyshev) can be designed using the separate IFDL package. IFDL is a suite of extensions and macros that you use to design FIR (Finite Impulse Response) and IIR (Infinite Impulse Response) filters and to apply them to your data. The IIR design software creates IIR coefficients based on bilinear transforms of analog prototype filters such as Bessel, Butterworth, and Chebyshev. See the WaveMetrics web site for more about IFDL.

Even without IFDL, you can create custom IIR filters by manually placing poles and zeros in the Z plane using the Pole and Zero Filter Design procedures. Copy the following line to your Procedure window and click the Compile button at the bottom of the procedure window:

```
#include <Pole And Zero Filter Design>
```

Then choose Pole and Zero Filter Design from the Analysis menu.

Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)

FindDimLabel

FindDimLabel(waveName, dimNumber, labelString)

Returns the index value corresponding to the label for the given dimension. Returns -1 if the label is for the entire dimension. Returns -2 if the label is not found.

Use *dimNumber* =0 for rows, 1 for columns, 2 for layers, or 3 for chunks.

FindLevel

FindLevel [*flags*] *waveName*, *level*

The FindLevel operation searches the named wave to find the X value at which the specified Y *level* is crossed.

Flags

/B= <i>box</i>	Sets box size for sliding average. If /B= <i>box</i> is omitted or <i>box</i> equals 1, no averaging is done. If you specify an even box size then the next higher (odd) integer is used. If you use a box size greater than 1, FindLevel will be unable to find a level crossing that occurs in the first or last $box/2 - 1$ points of the wave since these points don't have enough neighbors for computing the derived average wave values.
/EDGE= <i>e</i>	Specifies searches for either increasing or decreasing level crossing. <i>e</i> =1: Searches only for crossing where Y values are increasing as <i>level</i> is crossed from wave start towards wave end. <i>e</i> =2: Searches only for crossing where the Y values are decreasing as <i>level</i> is crossed from wave start towards wave end. <i>e</i> =0: Same as no /EDGE flag (searches for either increasing and decreasing level crossing).
/P	Computes the X crossing location in terms of point number. If /P is omitted, the level crossing location is computed in terms of X values.
/Q	Don't print results in history and don't report error if <i>level</i> is not found.
/R=(<i>startX</i> , <i>endX</i>)	Specifies an X range of the wave to search. You may exchange <i>startX</i> and <i>endX</i> to reverse the search direction.
/R=[<i>startP</i> , <i>endP</i>]	Specifies a point range of the wave to search. You may exchange <i>startP</i> and <i>endP</i> to reverse the search direction. If you specify the range as /R=[<i>startP</i>] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is searched.
/T= <i>dx</i>	Search for two level crossings. <i>dx</i> must be less than <i>minWidthX</i> , so you must also specify /M if you use /T. (FindLevel limits <i>dx</i> so that second search start isn't beyond where the first search for next edge will be.)
/T= <i>dx</i>	Searches for two level crossings.

Details

FindLevel scans through the wave comparing *level* to values derived from the Y values of the wave. Each derived value is a sliding average of the Y values.

FindLevel searches for two derived wave values that straddle *level*. If it finds these values it computes the X value at which *level* is located by linearly interpolating between the straddling Y values.

Note: FindLevel does not locate values exactly equal to *level*; it locates transitions through *level*. See **BinarySearch** for one method of locating exact values.

FindLevel reports its results by setting these variables:

v_flag	0: <i>level</i> was found. 1: <i>level</i> was not found.
V_LevelX	Interpolated X value at which <i>level</i> was found, or the corresponding point number if /P is specified.
v_rising	0: Y values at the crossing are decreasing from wave start towards wave end. 1: Y values at the crossing are increasing.

If you do not use the /Q flag then FindLevel also reports its results by printing them in the history area, and if *level* is not found FindLevel generates an error which puts up an error alert and also halts execution of any command line or macro that is in progress.

These X locations and distances are in terms of the X scaling of the named wave unless you use the /P flag, in which case they are in terms of point number.

V_LevelX is returned in terms of the X scaling of the named wave unless you use the /P flag, in which case it is in terms of point number.

FindLevels

The FindLevel operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **EdgeStats**, **FindLevels**, **FindValue**, and **PulseStats** operations and the **BinarySearch** and **BinarySearchInterp** functions.

FindLevels

FindLevels [*flags*] *waveName*, *level*

The FindLevels operation searches the named wave to find one or more X values at which the specified Y *level* is crossed.

Flags

/B= <i>box</i>	Sets box size for sliding average. See the FindLevel operation.
/D= <i>destWaveName</i>	Specifies wave into which FindLevels is to store the level crossing values. If /D is omitted, FindLevels creates a wave named W_FindLevels to store the level crossing values in.
/EDGE= <i>e</i>	Specifies searches for either increasing or decreasing level crossing. <i>e</i> =1: Searches only for crossings where the Y values are increasing as level is crossed from wave start towards wave end. <i>e</i> =2: Searches only for crossings where the Y values are decreasing as level is crossed from wave start towards wave end. <i>e</i> =0: Same as no /EDGE flag (searches for both increasing and decreasing level crossings).
/M= <i>minWidthX</i>	Sets the minimum X distance between level crossings. This determines where FindLevels searches for the next crossing after it has found a level crossing. The search starts <i>minWidthX</i> X units beyond the crossing. The default value for <i>minWidthX</i> is 0.
/N= <i>maxLevels</i>	Sets a maximum number of crossings that FindLevels is to find. The default value for <i>maxLevels</i> is the number of points in the specified range of <i>waveName</i> .
/P	Compute crossings in terms of points. See the FindLevel operation.
/Q	Doesn't print to history and doesn't abort if no levels are found.
/R=(<i>startX</i> , <i>endX</i>)	Specifies X range. See the FindLevel operation.
/R=[<i>startP</i> , <i>endP</i>]	Specifies point range. See the FindLevel operation.
/T= <i>dx</i>	Search for two level crossings. <i>dx</i> must be less than <i>minWidthX</i> , so you must also specify /M if you use /T. (FindLevels limits <i>dx</i> so that second search start isn't beyond where the first search for next edge will be.) See FindLevel for more about /T.

Details

The algorithm for finding a level crossing is the same one used by the FindLevel operation.

If FindLevels finds *maxLevels* crossings or can not find another level crossing, it stops searching.

FindLevels sets the following variables:

V_flag	0: <i>maxLevels</i> level crossings were found. 1: At least one but less than <i>maxLevels</i> level crossings were found. 2: No level crossings were found.
V_LevelsFound	Number of level crossings found.

See Also

The **FindLevel** operation for details about the level crossing detection algorithm and the /B, /P, /Q, /R, and /T flag values.

The FindLevels operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

FindListItem

FindListItem(*itemStr*, *listStr* [, *listSepStr* [, *start* [, *matchCase*]]])

The FindListItem function returns a numeric offset into *listStr* where *itemStr* begins. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use FindListItem to locate the start of an item in a string containing a "wave0;wave1;" style list such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

Use WhichListItem to determine the index of an item in the list.

If *itemStr* is not found, if *listStr* is "", or if *start* is not within the range of 0 to strlen(*listStr*)-1, then -1 is returned.

listSepStr, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

Details

ItemStr may have any length.

listStr is searched for the first instance of the item string bound by a *listSepStr* on the left and a *listSepStr* on the right. The returned number is the character index where the first character of *itemStr* was found in *listStr*.

The search starts from the character position in *listStr* specified by *start*. A value of 0 starts with the first character in *listStr*, which is the default if *start* is not specified.

listString is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

Only the first character of *listSepStr* is used.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

Examples

```
Print FindListItem("w1", "w0;w1;w2",)           // prints 3
Print FindListItem("v2", "v1,v2,v3",",",",")      // prints 3
Print FindListItem("v2", "v0,v2,v2",",",",", 4)    // prints 6
Print FindListItem("C", "a;c;c;c;")              // prints 4
Print FindListItem("C", "a;c;c;c;",",", 0, 0)       // prints 2
```

FindPeak

FindPeak [*flags*] *waveName*

The FindPeak operation searches for a minimum or maximum by analyzing the smoothed first and second derivatives of the named wave. Information about the peak position, amplitude, and width are returned in the output variables.

Flags

Some of the flags have the same meaning as for the FindLevel operation.

/B=box	Sets box size for sliding average.
/I	Modify the search criteria to accommodate impulses (peaks of one sample) by requiring only one value to exceed <i>minLevel</i> . The default criteria requires that two successive values exceed <i>minLevel</i> for a peak to be found (or two successive values be less than the /M level when searching for negative peaks). Impulses can also be found by omitting <i>minLevel</i> , in which case /I is superfluous.
/M=minLevel	Defines minimum level of a peak. /N changes this to maximum level (see Details).
/N	Searches for a negative peak (minimum) rather than a positive peak (maximum).
/P	Location output variables (see Details) are reported in terms of (floating point) point numbers. If /P is omitted, they are reported as X values.
/Q	Doesn't print to history and doesn't abort if no peak is found.

FindPeak

`/R=(startX,endX)` Specifies X range and direction for search.
`/R=[startP,endP]` Specifies point range and direction for search.

Details

FindPeak sets the following variables:

<code>V_flag</code>	Set only when using the <code>/Q</code> flag. 0: Peak was found. Any nonzero value means the peak was not found.
<code>V_LeadingEdgeLoc</code>	Interpolated location of the peak edge closest to <code>startX</code> or <code>startP</code> . If you use the <code>/P</code> flag, <code>V_LeadingEdgeLoc</code> is a point number rather than to an X value. If the edge was not found, this value is NaN.
<code>V_PeakLoc</code>	Interpolated X value at which the peak was found. If you use the <code>/P</code> flag, FindPeak sets <code>V_PeakLoc</code> to a point number rather than to an X value. Set to NaN if peak wasn't found.
<code>V_PeakVal</code>	The <i>approximate</i> Y value of the found peak. If the peak was not found, this value is NaN (Not a Number).
<code>V_PeakWidth</code>	Interpolated peak width. If you use the <code>/P</code> flag, <code>V_PeakWidth</code> is expressed in point numbers rather than as an X value. <code>V_PeakWidth</code> is never negative. If either peak edge was not found, this value is NaN.
<code>V_TrailingEdgeLoc</code>	Interpolated location of the peak edge closest to <code>endX</code> or <code>endP</code> . If you use the <code>/P</code> flag, <code>V_TrailingEdgeLoc</code> is a point number rather than to an X value. If the edge was not found, this value is NaN.

FindPeak computes the sliding average of the input wave using the BoxSmooth algorithm with the `box` parameter. The peak center is found where the derivative of this smoothed result crosses zero. The peak edges are found where the second derivative of the smoothed result crosses zero. Linear interpolation of the derivatives is used to more precisely locate the center and edges. The peak value is simply the greater of the two unsmoothed values surrounding the peak center (if `/N`, then the lesser value).

Without `/M`, a peak is found where the derivative crosses zero, regardless of the peak height.

If you use the `/M=minLevel` flag, FindPeak ignores peaks that are lower than *minLevel* (i.e., the Y value of a found peak will exceed *minLevel*) in the box-smoothed input wave. If `/N` is also specified (search for minimum), FindPeak ignores peaks whose amplitude is greater than *minLevel* (i.e., the Y value of a found peak will be *less* than *minLevel*).

Without `/I`, a peak must have two successive values that exceed *minLevel*. Use `/I` when you are searching for peaks that may have only one value exceeding *minLevel*.

The search for the peak begins at `startX` (or the first point of the wave if `/R` is not specified), and ends at `endX` (or the last point of the wave if no `/R`). Searching backwards is permitted, and exchanges the values of `V_LeadingEdgeLoc` and `V_TrailingEdgeLoc`.

FindPeak computes the sliding average of the input wave using the BoxSmooth algorithm with the `box` parameter. The peak center is found where the derivative of this smoothed result crosses zero. The peak edges are found where the second derivative of the smoothed result crosses zero. Linear interpolation of the derivatives is used to more precisely locate the center and edges. The peak value is simply the larger of the two unsmoothed values surrounding the peak center (if `/N`, it is the smaller value).

A simple automatic peak-finder is implemented in the procedure file:

```
#include <Peak AutoFind>
```

one of the `#include <Multi-peak fitting 1.3>` procedures that provides support for Gaussian, Lorentzian, and Voigt fitting functions. See the "Multi-peak fit" example experiment for details (:Examples:Curve Fitting: folder).

As you can see, FindPeak is not a high-accuracy measurement routine; it is intended as a simple peak-finder. Use the **PulseStats** operation for more precise statistics.

The FindPeak operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **FindLevel** operation for details about the `/B`, `/P`, `/Q`, and `/R` flag values.

FindPointsInPoly

FindPointsInPoly *xWaveName*, *yWaveName*, *xPolyWaveName*, *yPolyWaveName*

The FindPointsInPoly operation determines if points fall within a certain polygon. It can be used to write procedures that operate on a subset of data identified graphically in a graph.

Details

FindPointsInPoly determines which points in *yWaveName* vs *xWaveName* fall within the polygon defined by *yPolyWaveName* vs *xPolyWaveName*.

xWaveName must have the same number of points as *yWaveName* and *xPolyWaveName* must have the same number of points as *yPolyWaveName*.

FindPointsInPoly creates an output wave named *W_inPoly* with the same number of points as *xWaveName*. FindPointsInPoly indicates whether the point *yWaveName*[*p*] vs *xWaveName*[*p*] falls within the polygon by setting *W_inPoly*[*p*]=1 if it is within the polygon, or *W_inPoly*[*p*]=0 if it is not.

FindPointsInPoly uses integer arithmetic with a precision of about 1 part in 1000. This should be good enough for visually determined (hand-drawn) polygons but might not be sufficient for mathematically generated polygons.

The FindPointsInPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **GraphWaveDraw** operation.

FindRoots

FindRoots [*flags*] *funcspec*, *pWave* [, *funcspec*, *pwave* [, ...]]

FindRoots /*P=PolyCoefsWave*

The FindRoots operation determines roots or zeros of a specified nonlinear function or system of functions. The function or system of functions must be defined in the form of Igor user procedures.

Using the second form of the command, FindRoots finds all the complex roots of a polynomial with real coefficients. The polynomial coefficients are specified by *PolyCoefsWave*.

Flags for roots of nonlinear functions

- | | |
|---|--|
| <i>/B [= doBracket]</i> | Specifies bracketing for roots of a single nonlinear function only.
<i>doBracket=0</i> : Skips an initial check of the root bracketing values and the possible search for bracketing values. This means that you must provide good bracketing values via the <i>/L</i> and <i>/H</i> flags. See <i>/L</i> and <i>/H</i> flags for details on bracketing of roots. <i>/B</i> alone is the same as <i>/B=0</i> .
<i>doBracket=1</i> : Uses default root bracketing. |
| <i>/F=trustRegion</i> | Sets the expansion factor of the trust region for the search algorithm when finding roots of systems of functions. Smaller numbers will result in a more stable search, although for some functions larger values will allow the search to zero in on a root more rapidly. Default is 1.0; useful values are usually between 0.1 and 100. |
| <i>/I=maxIters</i> | Sets the maximum number of iterations in searching for a root to <i>maxIters</i> . Default is 100. |
| <i>/L=lowBracket</i>
<i>/H=highBracket</i> | <i>/L</i> and <i>/H</i> are used only when finding roots of a single nonlinear function. <i>lowBracket</i> and <i>highBracket</i> are X values that bracket a zero crossing of the function. A root is found between the bracketing values.
If <i>lowBracket</i> and <i>highBracket</i> are on the same side of zero, it will try to find a minimum or maximum between <i>lowBracket</i> and <i>highBracket</i> . If it is found, and it is on the other side of zero, Igor will find two roots.
If <i>lowBracket</i> and <i>highBracket</i> are on the same side of zero, but no suitable extreme point is found between, it will search outward from these values looking for a zero crossing. If it is found, Igor determines one root.
If <i>lowBracket</i> and <i>highBracket</i> are equal, it adds 1.0 to <i>highBracket</i> before looking for a zero crossing. |

	The default values for <i>lowBracket</i> and <i>highBracket</i> are zero. Thus, not using either <i>lowBracket</i> or <i>highBracket</i> is the same as <i>/L=0/H=1</i> .
<i>/Q</i>	Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.
<i>/T=tol</i>	Sets the acceptable accuracy to <i>tol</i> . That is, the reported root should be within $\pm tol$ of the real root.
<i>/X=xWave</i> <i>/X={x1, x2, ...}</i>	Sets the starting point for searching for a root of a system of functions. There must be as many X values as functions. The starting point can be specified with a wave having as many points as there are functions, or you can write out a list of X values in braces. If you are finding roots of a single function, use <i>/L</i> and <i>/H</i> instead. If you specify a wave, this wave is also used to receive the result of the root search.
<i>/Z=yValue</i>	Finds other solutions, that is, places where $f(x) = yValue$. FindRoots usually finds zeroes — places where $f(x) = 0$.

Flag for roots of polynomials

<i>/P=PolyCoefsWave</i>	Specifies a wave containing real polynomial coefficients. With this flag, it finds polynomial roots and does not expect to find user function names on the command line. The <i>/P</i> flag causes all other flags to be ignored.
-------------------------	---

Parameters

func specifies the name of a user-defined function.

pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified. It is intended for your private use to pass adjustable constants to your function.

These parameters occur in pairs. For a one-dimensional problem, use a single *func*, *pwave* pair. An N-dimensional problem requires N pairs unless you use the combined function form (see **Combined Format for Systems of Functions**).

Function Format for 1D Nonlinear Functions

Finding roots of a nonlinear function or system of functions requires that you realize the function in the form of an Igor user function of a certain form. In the FindRoots command you then specify the functions with one or more function names paired with parameter wave names. See **Finding Function Roots** on page III-275 for detailed examples.

The functions must have a particular form. If you are finding the roots of a single 1D function, it should look like this:

```
Function myFunc(w,x)
    Wave w
    Variable x
    return f(x)           // an expression ...
End
```

Replace “f(x)” with an appropriate expression. The FindRoots command might then look like this:

```
FindRoots /L=0 /H=1 myFunc, cw           // cw is a parameter wave for myFunc
```

Function Format for Systems of Multivariate Functions

If you need to find the roots of a system of multidimensional functions, you can use either of two forms. In one form, you provide N functions with N independent variables. You must have a function for each independent variable. For instance, to find the roots of two 2D functions, the functions must have this form:

```
Function myFunc1(w, x1, x2)
    Wave w
    Variable x1, x2
    return f1(x1, x2)      // an expression ...
End
Function myFunc2(w, x1, x2)
    Wave w
    Variable x1, x2
    return f2(x1, x2)      // an expression ...
End
```

In this case, the FindRoots command might look like this (where cw1 and cw2 are parameter waves that must be made before executing FindRoots):

```
FindRoots /X={0,1} myFunc1, cw1, myFunc2, cw2
```

You can also use a wave to pass in the X values. Make sure you have the right number of points in the X wave — it must have N points for a system of N functions.

```
Function myFunc1(w, xW)
  Wave w, xW
  return f1(xW[0], xW[1])      // an expression ...
End
Function myFunc2(w, xW)
  Wave w, xW
  return f2(xW[0], xW[1])      // an expression ...
End
```

Combined Format for Systems of Functions

For large systems of equations it may get tedious to write a separate function for each equation, and the FindRoots command line will get very long. Instead, you can write it all in one function that returns N Y values through a Y wave. The X values are passed to the function through a wave with N elements. The parameter wave for such a function must have N columns, one column for each equation. The parameters for equation N are stored in column N-1. FindRoots will complain if any of these waves has other than N rows.

Here is an template for such a function:

```
Function myCombinedFunc(w, xW, yW)
  Wave w, xW, yW
  yW[0] = f1(w[0][...], xW[0], xW[1],..., xW[N-1])
  yW[1] = f2(w[1][...], xW[0], xW[1],..., xW[N-1])
  ...
  yW[N-1] = fN(w[N-1][...], xW[0], xW[1],..., xW[N-1])
End
```

When you use this form, you only have one function and parameter wave specification in the FindRoots command:

```
Make/N=(nrows, nequations) paramWave
fill in paramWave with values
Make/N=(number of equations) guessWave
guessWave = {x0, x1, ..., xN}
FindRoots /X=guessWave myCombinedFunc, paramWave
```

FindRoots has no idea how many actual equations you have in the function. If it doesn't match the number of rows in your waves, your results will not be what you expect!

Coefficients for Polynomials

To find the roots of a polynomial, you first create a wave with the correct number of points. For a polynomial of degree N, create a wave with N+1 points. For instance, to find roots of a cubic equation you need a four-point wave.

The first point (row zero) of the wave contains the constant coefficient, the second point contains the coefficient for X, the third for X², etc.

Results for Nonlinear Functions and Systems of Functions

The FindRoots operation reports success or failure via the V_flag variable. A nonzero value of V_flag indicates the reason for failure:

V_flag	0:	Successful search for a root. Otherwise, the value indicates what went wrong:
	1:	User abort.
	3:	Exceeded maximum allowed iterations
	4:	/T=tol was too small. Reported by the root finder for systems of nonlinear functions.
	5:	The search algorithm wasn't making sufficient progress. It may mean that /T=tol was set to too low a value, or that the search algorithm has gotten trapped at a false root. Try restarting from a different starting point.
	6:	Unable to bracket a root. Reported when finding roots of single nonlinear functions.
	7:	Fewer roots than expected. Reported by the polynomial root finder. This may indicate that roots were successfully found, but some are doubled. Happens only rarely.

FindSequence

- 8: Decreased degree. Reported by the polynomial root finder. This indicates that one or more of the highest-order coefficients was zero, and a lower degree polynomial was solved.

The results of finding roots of a single 1D function are put into several variables:

V_numRoots	The number of roots found. Either 1 or 2.
V_Root	The root.
V_YatRoot	The Y value of the function at the root. <i>Always</i> check this; some discontinuous functions may give an indication of success, but the Y value at the found root isn't even close to zero.
V_Root2	Second root if FindRoots found two roots.
V_YatRoot2	The Y value at the second root.

Results for roots of a system of nonlinear functions are reported in waves:

W_Root	X values of the root of a system of nonlinear functions. If you used /X= <i>xWave</i> , the root is reported in your wave instead.
W_YatRoot	The Y values of the functions at the root of a system of nonlinear functions. Only one root is found during a single call to FindRoots.

Roots of a polynomial are reported in a wave:

W_polyRoots	A complex wave containing the roots of a polynomial. The number of roots should be equal to the degree of the polynomial, unless a root is doubled.
-------------	---

Finding Function Roots on page III-275.

The FindRoots operation uses the Jenkins-Traub algorithm for finding roots of polynomials:

Jenkins, M.A., Algorithm 493, Zeros of a Real Polynomial, *ACM Transactions on Mathematical Software*, 1, 178-189, 1975. Used by permission of ACM (1998).

FindSequence

FindSequence [*flags*] *srcWave*

The FindSequence operation finds the location of the specified sequence starting the search from the specified start point. The result of the search stored in V_value is the index of the entry in the wave where the first value is found or -1 if the sequence was not found.

Flags

/I= <i>wave</i>	Specifies an integer sequence wave for integer search.
/M= <i>val</i>	If there are repeating entries in the match sequence, <i>val</i> is a tolerance value that specifies the maximum difference between the number of repeats. So, for example, if the match sequence is aaabbccc and the <i>srcWave</i> contains a sequence aabbcc then the sequence will not be considered a match if <i>val</i> =0 but will be considered a match if <i>val</i> =1.
/S= <i>start</i>	Sets starting point of the search. If /S is not specified, start is 0.
/T= <i>tolerance</i>	Defines the tolerance (value \pm <i>tolerance</i> will be accepted) when comparing floating point numbers.
/U= <i>uValue</i>	Specifies the match sequence wave in case of unsigned long range.
/V= <i>rValue</i>	Specifies the match sequence wave in the case of single/double precision numbers.
/Z	No error reporting.

Details

If the match sequence is specified via the /V flag, it is considered to be a floating point wave (i.e., single or double precision) in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the default value 1.0^{-7} .

If the match sequence is specified via the /I flag, the sequence is assumed to be an integer wave (this includes both signed and unsigned char, signed and unsigned short as well as long). In this case *srcWave*

must also be of integer type and the operation searches for the sequence based on exact equality between the match sequence and entries in the wave as signed long integers.

If the match sequence is unsigned long wave use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

See Also

The **FindValue** operation.

FindValue

FindValue [*flags*] *srcWave*

FindValue [*flags*] *txtWave*

This operation finds the location of the specified value starting the search from the specified start point. The result of the search stored in V_value is the index of the entry in the wave where the value is found or -1 if not found.

Flags

/I= <i>ivalue</i>	Specifies an integer value for integer search.
/S= <i>start</i>	Sets start of search in the wave. If /S is not specified, start is set to 0.
/T= <i>tolerance</i>	Compares floating point numbers to define the tolerance (value \pm <i>tolerance</i> will be accepted).
/TEXT= <i>templateString</i>	Specifies a template string that will be searched for in <i>txtWave</i> .
/TXOP= <i>txOptions</i>	Specifies the search options using a combination of binary values
<i>txOptions</i>	Search Type
1	Case sensitive
2	Whole word
4	Whole wave element
/U= <i>uValue</i>	Specifies the match value in case of unsigned long range.
/V= <i>rValue</i>	Specifies the match value in the case of single/double precision numbers.
/Z	No error reporting.

Details

If the match value is specified via the /V flag, it is considered to be a floating point value in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the /T flag, the value 10^{-7} is used.

If the match value is specified via the /I flag, the value is assumed to be an integer. In this case *srcWave* must be of integer type and the operation searches for the value based on exact equality between the match value and entries in the wave as signed long integers.

If the match value is unsigned long use the /U flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

When searching for text in a text wave the operation creates the variable V_value as above but it also creates the variable V_startPos to specify the position of *templateString* from the start of the particular wave element.

See Also

The **FindSequence** operation.

FitFunc

FitFunc

Marks a user function as a user-defined curve fit function. By default, only functions marked with this keyword are displayed in the Function menu in the Curve Fit dialog.

If you wish other functions to be displayed in the Function menu, you can select the checkbox labelled "Show old-style functions (missing FitFunc keyword)".

See Also

User-Defined Fitting Function: Detailed Description on page III-212.

floor

floor(*num*)

The floor function returns the closest integer less than or equal to *num*.

See Also

The **round**, **ceil**, and **trunc** functions.

FontList

FontList(*separatorStr* [, *options*])

The FontList function returns a list of the installed fonts, separated by the characters in *separatorStr*.

Parameters

A maximum of 10 characters from *separatorStr* are appended to each font name as the output string is generated. *separatorStr* is usually ";".

Use *options* to limit the returned font list according to font type. It is restricted to returning only scalable fonts (TrueType, PostScript, or OpenType), which you can do with *options* = 1.

To get a list of nonscalable fonts (bitmap or raster), use:

```
String bitmapFontList = RemoveFromList(FontList(";",1), FontList(";",1))
```

(Most Mac OS X fonts are scalable, so bitmapFontList may be empty.)

Examples

```
Function SetFont(fontName)
  String fontName
  Prompt fontName,"font name:",popup,FontList(";")+ "default;"
  DoPrompt "Pick a Font", fontName
  Print fontName
  Variable type= WinType("") // target window type
  String windowName= WinName(0,127)
  if((type==1) || (type==3) || (type==7)) // graph, panel, layout
    Print "Setting drawing font for "+windowName
    Execute "SetDrawEnv fname=\""+fontName+"\" "
  else
    if( type == 5 ) // notebook
      Print "Setting font for selection in "+windowName
      Notebook $windowName font=fontName
    endif
  endif
End
```

Execute on the command line:

```
SetFont("")
```

See Also

The **FontSizeStringWidth**, **FontSizeHeight**, and **WinType** functions, and the **Execute**, **SetDrawEnv**, and **Notebook Operations**.

FontSizeHeight

FontSizeHeight(*fontNameStr*, *fontSize*, *fontstyle*)

The FontSizeHeight function returns the line height in pixels of any string when rendered with the named font and the given font style and size.

Parameters

fontNameStr is the name of the font, such as "Helvetica".

fontSize is the size (height) of the font in pixels.

fontStyle is text style (bold, italic, etc.). Use 0 for plain text.

Details

The returned height is the sum of the font's ascent and descent heights. Variations in *fontStyle* and typeface design cause the actual font height to be different than *fontSize* would indicate. (Typically a font "height" refers to only the ascent height, so the total height will be slightly larger to accommodate letters that descend below the baseline, such as g, p, q, and y).

FontSize is in pixels. To obtain the height of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

If the named font is not installed, FontSizeHeight returns NaN.

FontSizeHeight understands "default" to mean the current experiment's default font.

fontStyle is a binary coded integer with each bit controlling one aspect of the text style as follows:

- bit 0: Bold.
- bit 1: Italic.
- bit 2: Underline.
- bit 3: Outline (*Macintosh only*).
- bit 4: Shadow (*Macintosh only*).

To set bit 0 and bit 2 (bold, underline), use $2^0 + 2^2 = 1 + 4 = 5$ for *fontStyle*. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Examples

```
Variable pixels= 12 * ScreenResolution/72           // convert 12 points to pixels
Variable pixelHeight= FontSizeHeight("Helvetica",pixels,0)
Print "Height in points= ", pixelHeight * 72/ScreenResolution

Function FontIsInstalled(fontName)
  String fontName
  if( numtype(FontSizeHeight(fontName,10,0)) == 2 )
    return 0           // NaN returned, font not installed
  else
    return 1
  endif
End
```

See Also

The **FontList**, **FontSizeStringWidth**, **numtype**, and **ScreenResolution** functions.

FontSizeStringWidth

FontSizeStringWidth(*fontNameStr*, *fontSize*, *fontstyle*, *theStr*)

The FontSizeStringWidth function returns the width of *theStr* in pixels, when rendered with the named font and the given font style and size.

Parameters

fontNameStr is the name of the font, such as "Helvetica".

fontSize is the size (height) of the font in pixels.

fontStyle is text style (bold, italic, etc.). Use 0 for plain text.

theStr is the string whose width is being measured.

Details

If the named font is not installed, FontSizeStringWidth returns NaN.

for-endfor

FontSizeStringWidth understands “default” to mean the current experiment’s default font.

FontSize is in pixels. To obtain the width of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

fontStyle is a binary coded integer with each bit controlling one aspect of the text style as follows:

- bit 0: Bold.
- bit 1: Italic.
- bit 2: Underline.
- bit 3: Outline (*Macintosh only*).
- bit 4: Shadow (*Macintosh only*).

To set bit 0 and bit 2 (bold, underline), use $2^0 + 2^2 = 1 + 4 = 5$ for *fontStyle*. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Examples

```
Variable fsPix= 10 * ScreenResolution/72           // 10 point text in pixels
String text= "How long is this text?"
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text)
Print "width in inches= ", WidthPix / ScreenResolution
```

See Also

The **FontList**, **FontSizeHeight**, and **ScreenResolution** functions.

for-endfor

```
for(<initialize>;<exit test>;<update>)
  <loop body>
endfor
```

A for-endfor loop executes *loop body* code until *exit test* evaluates as FALSE, zero, or until a break statement is executed within the body code. When the loop starts, the *initialize* expressions are evaluated once. For each iteration, the *exit test* is evaluated at the beginning, and the *update* expressions are evaluated at the end.

See Also

For Loop on page IV-35 and **break** for more usage details.

FPClustering

FPClustering [*flags*] *srcWave*

The FPClustering operation performs cluster analysis using the farthest-point clustering algorithm. The input for the operation *srcWave* defines M points in N-dimensional space. Outputs are the waves W_FPCenterIndex and W_FPclusterIndex.

Flags

- /CAC Computes all the clusters specified by /MAXC.
- /CM Computes the center of mass for each cluster. The results are stored in the wave M_clustersCM in the current data folder. Each row corresponds to a single cluster with columns providing the respective dimensional components.
- /INCD Computes the inter-cluster distances. The result is stored in the current data folder in the wave M_InterClusterDistance, a 2D wave in which the [i][j] element contains the distance between cluster *i* and cluster *j*.
- /MAXC=*nClusters* Terminates the calculation when the number of clusters reaches the specified value. Note that this termination condition is sufficient but not necessary, i.e., the operation can terminate earlier if the farthest distance of an element from a hub is less than the average distance.
- /MAXR=*maxRad* Terminates the calculation when the maximum distance is less than or equal to *maxRad*.
- /NOR Normalizes the data on a column by column basis. The normalization makes each columns of the input span the range [0,1] so that even when *srcWave* contains columns that may be different by several orders of magnitude, the algorithm is not biased by a larger implied cartesian distance.
- /Q Don't print information to the history window.

/SHUB= <i>sHub</i>	Specifies the row which is used as a starting hub number. By default the operation uses the first row in <i>srcWave</i> .
/Z	No error reporting.

Details

The input for FPClustering is a 2D wave *srcWave* which consists of M rows by N columns where each row represents a point in N-dimensional space. *srcWave* can contain only finite real numbers and must be of type SP or DP. The operation computes the clustering and produces the wave W_FPCenterIndex which contains the centers or “hubs” of the clusters. The hubs are specified by the zero-based row number in *srcWave* which contains the cluster center. In addition, the operation creates the wave W_FPClusterIndex where each entry maps the corresponding input point to a cluster index. By default, the operation continues to add clusters as long as the largest possible distance is greater than the average intercluster distance. You can also stop the processing when the operation has formed a specified number of clusters (see /MAXC).

The variable V_max contains the maximum distance between any element and its cluster hub.

It is possible that in some circumstances you can get slightly different clustering depending on your starting point. The default starting hub is row zero of *srcWave* but you can use the /SHUB flag to specify a different starting point.

FPClustering computes the Cartesian distance between points. As a result, if the scale of any dimension is significantly larger than other dimensions it might bias the clustering towards that dimension. To avoid this situation you can use the /NOR flag which normalizes each column to the range [0,1] and hence equalizes the weight of each dimension in the clustering process.

Gonzalez, T., Clustering to minimize the maximum intercluster distance, *Theoretical Computer Science*, 38, 293-306, 1985.

fprintf

fprintf *refNum*, *formatStr* [, *parameter*]...

The fprintf operation prints formatted output to a text file.

Parameters

refNum is a file reference number from the **Open** operation used to open the file.

formatStr is the format string, as used by the **printf** operation.

parameter varies depending on *formatStr*.

Details

If *refNum* is 1, fprintf will print to the history area instead of to a file, as if you used printf instead of fprintf. This useful for debugging purposes.

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC), Apple events (*Macintosh*) or DDE (*Windows*). Data that would normally be written to a file is appended to the PPC, Apple event or DDE result packet.

The fprintf operation supports numeric (real only) and string fields from structures. All other field types will cause a compile error.

See Also

The **printf** operation for complete format and parameter descriptions. The **Open** operation and **Creating Formatted Text** on page IV-184.

FReadLine

FReadLine [**/N/T**] *refNum*, *stringVarName*

The FReadLine operation reads bytes from a file into the named string variable. The read starts at the current file position and continues until a terminator character is read, the end of the file is reached, or the maximum number of characters is read.

Parameters

refNum is a file reference number from the **Open** operation used to create the file.

Flags

/N=n Specifies the maximum number of characters to read.
/T=termcharStr Specifies the terminator character.
/T=(num2char(13)) specifies carriage return (CR, ASCII code 13).
/T=(num2char(10)) specifies linefeed (LF, ASCII code 10).
/T=";" specifies the terminator as a semicolon.
/T="" specifies the terminator as null (ASCII code 0).
See **Details** for default behavior regarding the terminator.

Details

If **/N** is omitted, there is no maximum number of characters to read. When reading lines of text from a normal text file, you will not need to use **/N**. It may be of use in specialized cases, such as reading text embedded in a binary file.

If **/T** is omitted, FReadLine will terminate on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.) FReadLine reads whichever of these appears in the file, terminates the read, and returns just a CR in the output string. This default behavior transparently handles files that use CR, LF, CRLF, or LFCR as the terminator and will be suitable for most cases.

If you use the **/T** flag, then FReadLine will terminate on the specified character only and will return the specified character in the output string.

Once you have read all of the characters in the file, FReadLine will return zero characters via *stringVarName*. The example below illustrates testing for this.

Example

```
Function PrintAllLinesInFile()
  Variable refNum
  Open/R refNum as ""           // Display dialog
  if (refNum == 0)
    return -1                   // User canceled
  endif
  Variable lineNumber, len
  String buffer
  lineNumber = 0
  do
    FReadLine refNum, buffer
    len = strlen(buffer)
    if (len == 0)
      break                     // No more lines to be read
    endif
    Printf "Line number %d: %s", lineNumber, buffer
    if (CmpStr(buffer[len-1], "\r") != 0) // Last line has no CR ?
      Printf "\r"
    endif
    lineNumber += 1
  while (1)
  Close refNum
  return 0
End
```

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

FSetPos

FSetPos *refNum*, *filePos*

The **FSetPos** operation attempts to set the current file position to the given position.

Parameters

refNum is a file reference number obtained from the **Open** operation when the file was opened.

filePos is the desired position of the file in bytes from the start of the file.

Details

FSetPos generates an error if *filePos* is greater than the number of bytes in the file. You can ascertain this limit with the **FStatus** operation.

When a file that is open for writing is closed, any bytes past the end of the current file position are deleted by the operating system. Therefore, if you use **FSetPos**, make sure to set the current file position properly before closing the file.

See Also

The **Open** and **FStatus** operations.

FStatus

FStatus *refNum*

The FStatus operation provides file status information for a file.

Parameters

refNum is a file reference number obtained from the **Open** operation.

Details

FStatus sets the following variables:

V_flag	Nonzero (true) if <i>refNum</i> is valid, in which case FStatus sets the other variables as well.
V_filePos	Current file position for the file in bytes from the start.
V_logEOF	Total number of bytes in the file.
S_fileName	Name of the file.
S_path	Path from the volume to the folder containing the file. For example, "hd:Folder1:Folder2:". This is suitable for use as an input to the NewPath operation. Note that on the Windows operating system Igor uses a colon between folders instead of the Windows-standard backslash to avoid confusion with Igor's use of backslash to start an escape sequence (see Escape Characters in Strings on page IV-13).
S_info	Keyword-packed information string.

The keyword-packed information string for S_info consists of a sequence of sections with the following form: *keyword:value*; You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions.

Here are the keywords for S_info:

Keyword	Type	Meaning
PATH	string	Name of the symbolic path in which the file is located. This will be empty if there is no such symbolic path.
WRITEABLE	number	1 if file can be written to, 0 if not.

See Also

The **Open** operation.

FTPDownload

FTPDownload [*flags*] *urlStr*, *localPathStr*

The FTPDownload operation downloads a file or a directory from an FTP server on the Internet.

Warning: When you download a file or directory using the path and name of a file or directory that already exists on your local hard disk, all previous contents of the local file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-191.

FTPDownload sets a variable named V_flag to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the /Z flag, can be used to allow procedures to continue to execute if an FTP error occurs.

If the operation succeeds, FTPDownload sets a string named S_Filename to the full file path of the downloaded file. This is useful in conjunction with the /I flag.

Parameters

urlStr specifies the file or directory that you want to download. It is constructed of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

urlStr must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *urlStr* must not end with a slash.

localPathStr and *pathName* specify the name to use for the file or directory that will be created on your hard disk. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-382 for details on forming the path.

localPathStr must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPDownload displays a dialog through which you can identify the local file or directory in the following cases:

1. You have used the /I (interactive) flag.
2. You did not completely specify the location of the local file or directory via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent file or directory.
4. The specified local file or directory exists and you have not used the /O (overwrite) flag.

See **Examples** for examples of constructing a URL and local path.

Flags

/B= <i>binhex</i>	<p>Sets binhex file expansion (Macintosh only; ignored on Windows).</p> <p>0: Don't expand binhexed files (default).</p> <p>1: Expands binhexed files.</p> <p>When downloaded binhex files are debinhexed, it is done by the Mac OS URL Manager. If you download a file named Test.hqx and specify <i>binhex</i>=1, the URL Manager downloads Test.hqx and then debinhexes it, producing Test. It leaves both Test.hqx and Test on your hard disk drive. Also, if Test already existed in the destination folder, it names the new file Test1 instead of Test.</p> <p>The URL Manager documentation states: "If the Stuffit Engine is installed in the System Folder, it is used to expand the file in any way supported by Stuffit." However, in our testing using a ".sit" file on Mac OS 8.6 with URL Access extension version 1.01, this did not work.</p>
/D	Downloads a complete directory. Omit it if you are downloading a file.
/I	Interactive mode which will prompt you to specify the name and location of the file or directory to be created on the local hard disk.
/M= <i>messageStr</i>	Specifies the prompt message used by the dialog in which you specify the name and location of the file or directory to be created.
/N= <i>portNumber</i>	Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the /N flag.
/O	Overwrites without asking permission any local file or directory whose name is in conflict with the file or directory being downloaded.
/P= <i>pathName</i>	<p>Contributes to the specification of the file or directory to be created on your hard disk. <i>pathName</i> is the name of an existing symbolic path. See Examples.</p>
/S= <i>showProgress</i>	<p>Displays a progress dialog (Macintosh only; ignored on Windows).</p> <p>0: No progress dialog.</p> <p>1: Show a progress dialog (default).</p>
/T= <i>transferType</i>	<p>Transfers in image binary mode (Windows only; ignored on Macintosh).</p> <p>0: Image (binary) transfer (default).</p> <p>1: ASCII transfer.</p> <p>See FTP Transfer Types on page IV-194 for more discussion.</p>
/U= <i>userNameStr</i>	Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if <i>userNameStr</i> is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.
/V= <i>diagnosticMode</i>	<p>Determines what kind of diagnostic messages FTPDownload will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:</p> <p>Bit 0: Show basic diagnostics. Currently, this displays the URL and the local path in the history.</p> <p>Bit 1: Show errors. This displays additional information when errors occur.</p>

Bit 2: Show status. This displays status information returned by the operating system to FTPDownload.

The default value for this parameter is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7, to include the OS status information.

On Windows, the OS status information consists of the replies sent from the FTP server to your local computer. These replies can often be helpful when debugging problems, although you may have to learn about the FTP protocol to understand all of them.

On Macintosh, the OS status is useless and sometimes misleading information such as "Aborting...", which appears when you do a successful download!

See **FTP Troubleshooting** on page IV-195 for other troubleshooting tips.

/W=passwordStr

Specifies the password to be used when logging in to the FTP server. Use this flag if you have an account on the FTP server.

If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the */W="<your email address>"* flag.

Note: Don't use FTPDownload for applications where sensitive passwords are required because the password will appear in procedure files and in the history area.

/Z

Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the *V_flag* variable to see if the transfer succeeded. *V_flag* will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

Examples

Download a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPDownload url, localPath
```

Download a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPDownload/P=$pathName url, fileName
```

Download a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPDownload/D url, localPath
```

The **FTPUUpload** operation and **File Transfer Protocol (FTP)** on page IV-191.

FTPUUpload

FTPUUpload [*flags*] *urlStr*, *localPathStr*

The FTPUpload operation uploads a file or a directory to an FTP server on the Internet.

Warning: When you upload a file or directory to an FTP server, all previous contents of the server file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-191.

FTPUpload sets a variable named *V_flag* to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the */Z* flag, can be used to allow procedures to continue to execute if an FTP error occurs.

During development on Macintosh, we experienced a problem uploading directories that contains subdirectories. See **FTP Problems** on page IV-195 for details.

Parameters

urlStr specifies the file or directory to be created on the FTP server. It is constructed of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a

path (e.g., "/Test/TestFile1.txt"). For example:
 "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

urlStr must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory. In the case of a directory, *urlStr* must not end with a slash.

localPathStr and *pathName* specify the name and location on your hard disk of the local file to be uploaded. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-382 for details on forming the path.

localPathStr must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPUpload displays a dialog through which you can identify the file or directory to be uploaded in the following cases:

1. You have used the /I (interactive) flag.
2. You did not completely specify the location of the file or folder to be uploaded via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent directory.

See **Examples** for examples of constructing a URL and local path.

Flags

/B= <i>binhex</i>	<p>Sets binhex file expansion (Macintosh only; ignored on Windows).</p> <p>0: Don't expand binhexed files (default).</p> <p>1: Do expand binhexed files.</p> <p>Binhexes uploaded files if the file type is not 'TEXT' and the file has a resource fork. This is necessary to preserve the data in the resource fork of Macintosh files.</p> <p>Files created by Igor 3.1 and later do not contain any essential data in the resource fork. Although the Mac OS URL Manager documentation does not state it, it appears that the URL Manager automatically appends the extension ".hqx" to the name of the binhexed file uploaded to the server.</p>
/D	Uploads a complete directory. Omit it if you are uploading a file.
/I	Interactive mode which displays a dialog for choosing the local file or directory to be uploaded.
/M= <i>messageStr</i>	Specifies the prompt message used by the dialog in which you choose the local file or directory to be uploaded.
/N= <i>portNumber</i>	Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the /N flag.
/O	Overwrite. This flag is accepted by FTPUpload but has no effect. FTPUpload always overwrites the specified server file or directory, whether /O is used or not.
/P= <i>pathName</i>	Contributes to the specification of the file or directory to be uploaded. <i>pathName</i> is the name of an existing symbolic path. See Examples .
/S= <i>showProgress</i>	<p>Displays a progress dialog (Macintosh only; ignored on Windows).</p> <p>0: No progress dialog.</p> <p>1: Shows a progress dialog (default).</p>
/T= <i>transferType</i>	<p>Transfers in image binary mode (Windows only; ignored on Macintosh).</p> <p>0: Image (binary) transfer (default).</p> <p>1: ASCII transfer.</p> <p>See FTP Transfer Types on page IV-194 for more discussion.</p>
/U= <i>userNameStr</i>	Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if <i>userNameStr</i> is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.
/V= <i>diagnosticMode</i>	<p>Determines what kind of diagnostic messages FTPUpload will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:</p> <p>Bit 0: Show basic diagnostics. Currently, this displays the URL and the local path in the history.</p>

Bit 1: Show errors. This displays additional information when errors occur.

Bit 2: Show status. This displays status information returned by the operating system to FTPUpload.

The default value for this parameter is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7, to include the OS status information.

On Windows, the OS status information consists of the replies sent from the FTP server to your local computer. These replies can often be helpful when debugging problems, although you may have to learn about the FTP protocol to understand all of them.

On Macintosh, the OS status is useless and sometimes misleading information such as "Aborting...", which appears when you do a successful upload!

See **FTP Troubleshooting** on page IV-195 for other troubleshooting tips.

/W=passwordStr Specifies the password used when logging in to the FTP server. Use this flag if you have an account on the FTP server.

If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the */W=<your email address>* flag.

Note: Don't use FTPUpload for applications where sensitive passwords are required since the password will appear in procedure files and in the history area.

/Z Errors are not fatal. Will not abort procedure execution if an error occurs.

Your procedure can inspect the *V_flag* variable to see if the transfer succeeded. *V_flag* will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

Examples

Upload a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPUpload url, localPath
```

Upload a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPUpload/P=$pathName url, fileName
```

Upload a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPUpload/D url, localPath
```

The **FTPDownload** operation and **File Transfer Protocol (FTP)** on page IV-191.

FuncFit

FuncFit [*flags*] *fitFuncName*, *cwaveName*, *waveName* [*parameters*]

FuncFit [*flags*] {*fitFuncSpec*}, *waveName* [*parameters*]

The FuncFit operation performs a curve fit to a user defined function, or to a sum of fit functions using the second form (see **Fitting Sums of Fit Functions** on page V-173). Fitting can be done using any method that can be selected using the */ODR* flag (see **CurveFit** for details).

Flags

See **CurveFit** for all available flags.

Parameters

Note: As with the **CurveFit** operation, all parameters must follow *waveName*. All flags must appear immediately after the operation name (FuncFit).

/E=ewaveName A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.

<i>fitFuncName</i>	The user-defined function to fit to, which can be a function taking multiple independent variables (see also FuncFitMD). Multivariate fitting with FuncFit <i>requires</i> <i>/X=xwaveSpec</i> .
<i>fitFuncSpec</i>	List of fit functions and coefficient waves, with some optional information. Using this format fits a model consisting of the sum of the listed fit functions. Intended for fitting multiple peaks, but probably useful for other applications as well. See Fitting Sums of Fit Functions on page V-173.
<i>/STRC=structureInstance</i>	Used only with Structure Fit Functions on page III-221. When using a structure fit function, you must specify an instance of the structure to FuncFit. This will be an instance that has been initialized by a user-defined function that you write in order to invoke FuncFit.
<i>/X=xwaveSpec</i>	An optional wave containing X values for each of the input data values. If the fitting function has more than one independent variable, <i>xwaveSpec</i> is required and must be either a 2D wave with a column for each independent variable, or a list of waves, one for each independent variable. A list must be in braces: <i>/X={xwave0, xwave1, ...}</i> . There must be exactly one column or wave for each independent variable in the fitting function.

Other parameters are used as for the **CurveFit** operation, with some exceptions for multivariate fits.

Details for Multivariate Fits

The dependent variable data wave, *waveName*, must be a 1D wave even for multivariate fits. For fits to data in a multidimensional wave, see **FuncFitMD**.

For multivariate fits, the auto-residual (*/R* with no wave specified) is calculated and appended to the top graph if the dependent variable data wave is graphed in the top graph as a simple 1D trace. Auto residuals are calculated but not displayed if the data are displayed as a contour plot.

The autodeviate wave (*/D* with no wave specified) for multivariate fits has the same number of points as the data wave, with a model value calculated at the X values contained in the wave or waves specified with */X=xwaveSpec*.

Confidence bands are not supported for multivariate fits.

Wave Subrange Details

Almost any wave you specify to FuncFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-267 for details). See **Wave Subrange Details** on page V-82 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for CurveFit apply to FuncFit as well.

In addition to the waves discussed in the CurveFit documentation, it is possible to use subranges when specifying the coefficient wave and the epsilon wave. Since the coefficient wave and epsilon wave must have the same number of points, it might make sense to make them two columns from a single multicolumn wave. For instance, here is an example in which the first column is used as the coefficient wave, the second is used as the epsilon wave, and the third is used to save a copy of the initial guesses for future reference:

```
Make/D/N=(5, 3) myCoefs
myCoefs[][0] = {1,2,3,4,5}           // hypothetical initial guess
myCoefs[][1] = 1e-6                  // reasonable epsilon values
myCoefs[][2] = myCoefs[p][0]         // save copy of initial guess
FuncFit myFitFunc, myCoefs[][0] myData /E=myCoefs[][1] ...
```

You might have a fit function that uses a subset of the coefficients that are used by another. It might be useful to use a single wave for both. Here is an example in which a function that takes four coefficients is used to fit a subset of the coefficients, and then that solution is used as the initial guess for a function that takes six coefficients:

```
Make/D/N=6 Coefs6={1,2,3,4,5,6}
FuncFit Fit4Coefs, Coefs6[0,3] fitfunc4Coefs ...
FuncFit Fit6Coefs, Coefs6 ...
```

Naturally, the two fit functions must be worked out carefully to allow this.

Fitting Sums of Fit Functions

If Igor encounters a left brace at the beginning of the fit function name, it expects a list of fit functions to be summed during the fit. This is useful for, for instance, fitting several peaks in a data set to a sum of peak functions.

The fit function specification includes at least the name of the fitting function and an associated coefficient wave. A sum of fit functions requires multiple coefficient waves, one for each fit function. Any coefficient wave-related options must be specified in the fit function specification via keyword-value pairs.

The syntax of the sum-of-fit-functions specification is as follows:

```
{func1, coef1, keyword=value},{func2, coef2, keyword=value}, ...}
```

or

```
{string=fitSpecStr}
```

Within outer braces, each fit function specification is enclosed within inner braces. You can use one or more fit function specifications, with no intrinsic limit on the number of fit functions.

The second format is available to overcome limitations on the length of a command line in Igor. This format is just like the first, but everything inside the outer braces is contained in a string expression (which may be just a single string variable).

You can use any fit function that can be used for ordinary fitting, including the built-in functions that are available using the CurveFit operation. If you should write a user-defined fitting function with the same name as a built-in fit function, the user-defined function will be used (this is strongly discouraged).

Every function specification must include an appropriate coefficient wave, pre-loaded with initial guesses.

The comma between each function specification is optional.

The keyword-value pairs are optional, and are used to communicate further options on a function-by-function basis. Available keywords are:

HOLD=holdstr	Indicates that a fit coefficient should be held fixed during fitting. <i>holdstr</i> works just like the hold string specified via the /H flag for normal fitting. If you include HOLD in a string expression, you must escape the quotation marks around the hold string.
CONST={constants}	Sets the values of constants in the fitting function. So far, only two built-in functions take constants: exp_XOffset and dbexp_XOffset. They each take just one constant (the X offset), so you will have a "list" of one number inside the braces.
EPSW=epsilonWave	Specifies a wave holding epsilon values. Use only with a user-defined fitting function to set the differencing interval used to calculate numerical estimates of derivatives of the fitting function.
STRC=structureInstance	Specifies an instance of the structure to FuncFit when using a structure fit function. <i>structureInstance</i> is an instance that was initialized by a user-defined function that invokes FuncFit. This keyword (and structure fitting functions) can be used only when calling FuncFit from within a user-defined function. See Structure Fit Functions on page III-221 for more details.

For more details, and for examples of sums of fit functions in use, **Fitting Sums of Fit Functions** on page III-209.

See Also

The **CurveFit** operation for parameter details. See also **FuncFitMD** for user-defined multivariate fits to data in a multidimensional wave.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-157, especially the section **Fitting to a User-Defined Function** on page III-168.

For details on the form of a user-defined function, see **User-Defined Fitting Function: Detailed Description** on page III-212.

FuncFitMD

FuncFitMD [*flags*] *fitFuncSpec*, *cwaveName*, *waveName* [*parameters*]

The FuncFitMD operation performs a curve fit to the specified multivariate user defined *fitFuncSpec*. FuncFitMD handles gridded data sets in multidimensional waves. Most parameters and flags are the same as for the **CurveFit** and **FuncFit** operations; differences are noted below.

cwaveName is a 1D wave containing the fitting coefficients, and *functionName* is the user-defined fitting function, which has 2 to 4 independent variables.

Flags

/L=dimSize Sets the dimension size of the wave created by the auto-trace feature, that is, */D* without destination wave. The wave *fit_waveName* will be a multidimensional wave of the same dimensionality as *waveName* that has *dimSize* elements in each dimension. That is, if you are fitting to a matrix wave, *fit_waveName* will be a square matrix that has dimensions *dimSize* X *dimSize*. **Beware:** *dimSize* = 100 requires 100 million points for a 4-dimensional wave!

Parameters

Note: As with the **CurveFit** operation, all parameters must follow *waveName*. All flags must appear immediately after the operation name (FuncFitMD).

/E=ewaveName A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.

/T=twaveName Like */X* except for the T independent variable. This is a 1D wave having as many elements as *waveName* has chunks.

/X=xwaveName The X independent variable values for the data to fit come from *xwaveName* instead of from the X scaling of *waveName*. This is a 1D wave having as many elements as *waveName* has rows.

/Y=ywaveName Like */X* except for the Y independent variable. This is a 1D wave having as many elements as *waveName* has columns.

/Z=ywaveName Like */X* except for the Z independent variable. This is a 1D wave having as many elements as *waveName* has layers.

Details

Auto-residual (*/R* with no wave specified) and auto-trace (*/D* with no wave specified) for functions having two independent variables are plotted in a separate graph window if *waveName* is plotted as a contour or image in the top graph. An attempt is made to plot the model values and residuals in the same way as the input data.

By default the auto-trace and auto-residual waves are 50x50 or 25x25x25 or 15x15x15x15. Use */L=dimSize* for other sizes. Make your own wave and use */D=waveName* or */R=waveName* if you want a wave that isn't square. In this case, the wave dimensions must be the same as the dependent data wave.

Confidence bands are not available for multivariate fits.

Wave Subrange Details

Almost any wave you specify to FuncFitMD can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command; see **Subrange Display Syntax** on page II-267 for details. Note that the dependent variable data (*waveName*) must be a multidimensional wave; this requires an extension of the subrange syntax to allow a multidimensional subrange. See **Wave Subrange Details** on page V-173 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for **CurveFit** apply to FuncFitMD as well.

A subrange could be used to pick a plane from a 3D wave for fitting using a fit function taking two independent variables:

```
Make/N=(100,100,3) DepData
FuncFitMD fitfunc2D, myCoefs, DepData[ ] [0] ...
```

See Also

The **CurveFit** operation for parameter details.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-157, especially the section **Fitting to a User-Defined Function** on page III-168.

For details on the form of a user-defined function, see **User-Defined Fitting Function: Detailed Description** on page III-212.

FUNCREF

FUNCREF *protoFunc func* [= *funcSpec*]

Within a user function, FUNCREF is a reference that creates a local reference to a function or a variable containing a function reference.

Function

When passing a function as an input parameter to a user function, the syntax is:

```
FUNCREF protoFunc func
```

In this FUNCREF reference, *protoFunc* is a function that specifies the format of the function that can be passed by the FUNCREF, and *func* is a function reference used as an input parameter.

When you declare a function reference variable within a user function, the syntax is:

```
FUNCREF protoFunc func = funcSpec
```

Here, the local FUNCREF variable, *func*, is assigned a *funcSpec*, which can be a literal function name, a \$ string expression that evaluates at runtime, or another FUNCREF variable.

See Also

Function References on page IV-67 for an example and further usage details.

Function

```
Function [/D[/C]][/S] functionName([parameters])
```

The Function keyword introduces a function definition. The optional flags specify the return value type, if any, for the function.

Flags

/C	Complex function.
/D	Double-precision function. Obsolete, included for backward compatibility.
/D/C	Double-precision complex function.
/S	String function.

See Also

Chapter IV-3, **User-Defined Functions** and **Function Syntax** on page IV-28 for further information.

FunctionInfo

```
FunctionInfo(functionNameStr [, procedureWinTitleStr])
```

The FunctionInfo function returns a keyword-value pair list of information about the user-defined or external function name in *functionNameStr*.

Parameters

functionNameStr a string expression containing the name of a user-defined or external function.

A user-defined function can be specified in `module#function` format (see **The ModuleName Pragma** on page IV-40). This format is required if the function is a static function (unless *procedureWinTitleStr* is specified).

The optional *procedureWinTitleStr* can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf") in which to search for the named user-defined function. The information about the named function in the specified procedure window is returned.

This parameter makes it possible to select one of several static functions with identical names among different procedure windows, even if they do not contain a `#pragma moduleName=myModule` statement.

If `SetIgorOption IndependentModuleDev=1`, *procedureWinTitleStr* can also be a title followed by an independent module name in brackets to return information about the named function in the procedure window of the given title that belongs to named independent module. (See **The IndependentModule Pragma** on page IV-40 about independent modules.)

procedureWinTitleStr can also be just an independent module name in brackets to return information about the named nonstatic function in any procedure window that belongs to named independent module.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

User-Defined and External Functions

Keyword	Information Following Keyword
NAME	The name of the function. Same as contents of <i>functionNameStr</i> in most cases. Just the function name if you use the <code>module#function</code> format.
TYPE	Value is "UserDefined" or "XFunc".
RETURNTYPE	Number giving the return type of the function. See the table Return Type and Parameter Type Codes on page V-178.
N_PARAMS	Number of parameters for this function.
PARAM_n_TYPE	Number encoding the type of each parameter. There will be N of these keywords, one for each parameter. The part shown as <i>n</i> will be a number from 0 to N.

See **Examples** for a method for decoding these keywords.

User-Defined Functions Only

Keyword	Information Following Keyword
PROCWIN	Title of procedure window containing the function definition.
MODULE	Module containing function definition (see The ModuleName Pragma on page IV-40).
INDEPENDENTMODULE	Independent module containing function definition (see The IndependentModule Pragma on page IV-40).
SPECIAL	The value part has one of three values: no: Not a "special" function. static: Is a static function. Use the <code>module#function</code> format to get info about static functions. override: Function is an override function. See Function Overrides on page IV-66.
SUBTYPE	The function subtype, for instance FitFunc . See Procedure Subtypes on page V-8 for others.
PROCLINE	Line number within the procedure window of the function definition.
VISIBLE	Either "Yes" or "No". Set to No in the unlikely event that the function is defined in an invisible file.
N_OPT_PARAMS	Number of optional parameters. Usually zero.

External Functions Only

Keyword	Information Following Keyword
XOP	Name of the XOP module containing the function.

Functions can return either a numeric value or a string. A numeric value is always double precision and may be complex. Thus, the return type will always be one of the values 4 (numeric), 5 (4+1 for complex numeric) or 8192 (string).

Return Type and Parameter Type Codes

Type	Code	Code in Hex
Complex	1	0x1
Variable	4	0x4
Single Precision	2	0x2
Double Precision	4	0x4
Byte	8	0x8
16-bit Integer	16	0x10
32-bit Integer	32	0x20
Unsigned	64	0x40
Structure	512	0x200
Function reference	1024	0x400
Pass by reference parameter	4096	0x1000
String	8192	0x2000
Wave	16384	0x4000

These codes may be combined to indicate combinations of attributes. For instance, the code for a variable is 4 and the code for complex is 1. Consequently, the code for a complex variable is 5. The code for a complex variable passed by reference is $(4+1+4096) = 4101$.

Variables are always double-precision, hence the code of 4.

Waves may have a variety of codes. Numeric waves will combine with one of the number type codes such as 2 or 16. This does not reflect the numeric type of any actual wave, but rather any flag you may have used in the Wave reference. Thus, if the beginning of your function looks like

```
Function myFunc(w)
    Wave w
```

the code for the parameter w will be 16386 ($16384 + 2$) indicating a single-precision wave. You can use a numeric type flag with the Wave reference:

```
Function myFunc(w)
    Wave/I w
```

In this case, the code will be 16416 ($16384 + 32$).

Such codes are not very useful, as it is very rare to use a numeric type flag because the numeric type will be resolved correctly at runtime regardless of the flag.

A text wave has no numeric type, so its code is exactly 16384. Thus, the numeric type part of the code for a numeric wave serves to distinguish a numeric wave from a text wave.

Examples

This function formats function information nicely and prints it in the history window in an organized fashion. You can copy it into the Procedure window to try it out. It uses the function `interpretParamType()` below to print a human-readable version of the parameter and return types. To try `PrintFuncInfo()`, you will need to copy the code for `interpretParamType()` as well.

```
Function PrintFuncInfo(FunctionName)
    String FunctionName
    String infostr = FunctionInfo(FunctionName)
    if (strlen(infostr) == 0)
        print "The function "+FunctionName+" does not exist."
        return -1
    endif
    print "Name: ", StringByKey("NAME", infostr)
```

```

String typeStr = StringByKey("TYPE", infostr)
print "Function type: ", typeStr
Variable IsUserDefined = CmpStr(typeStr, "UserDefined")==0
// It's not really necessary to use an IF statement here;
// it simply prevents lines with blank information being printed for an XFUNC.
if (IsUserDefined)
    print "Module: ", StringByKey("MODULE", infostr)
    print "Procedure window: ", StringByKey("PROCWIN", infostr)
    print "Subtype: ", StringByKey("SUBTYPE", infostr)
    print "Special? ", StringByKey("SPECIAL", infostr)
    // Note use of NumberByKey to get a numeric key value
    print "Line number: ", NumberByKey("PROCLINE", infostr)
endif

// See function interpretParamType() below for example of
// interpreting type information

Variable dummy = NumberByKey("RETURN_TYPE", infostr)
String dummyStr = interpretParamType(dummy)
print "Return type: ", dummy, dummyStr

Variable nparams = NumberByKey("N_PARAMS", infostr)
print "Number of Parameters: ", nparams

Variable nOptParams = 0
if (IsUserDefined)
    nOptParams = NumberByKey("N_OPT_PARAMS", infostr)
    print "Optional Parameters: ", nOptParams
endif

Variable i
for (i = 0; i < nparams; i += 1)
    // Note how the PARAM_n_TYPE keyword string is constructed here
    String paramKeyStr = "PARAM_"+num2istr(i)+"_TYPE"
    Variable ptype = NumberByKey(paramKeyStr, infostr)

    String output = "Parameter "+num2istr(i)+"; "
    output += "type as number: "+num2istr(ptype)+"; "
    output += "type as string: "+interpretParamType(ptype)
    print output
endfor
End

```

Function that creates a human-readable string with information about parameter and return types. Note that various attributes of the type info is tested using the bitwise AND operator (&) to test for individual bits. The constants are expressed as hexadecimal values (prefixed with "0x") to make them more readable (at least to a programmer). Otherwise, 0x4000 would be 16384; at least, 0x4000 is clearly a single-bit constant.

```

Function/S interpretParamType(ptype)
    Variable ptype
    String typeStr = ""
    // flag to tell whether to print out "complex" and "real"
    // We don't want that information on strings and text waves
    Variable wantRC = 1
    if (ptype & 0x4000) // test for WAVE bit set
        typeStr += "Wave "
        // If *only* wave bit set, its a text wave. A numeric
        // wave has some other information causing the value
        // to be different from 0x4000
        if (ptype == 0x4000)
            typeStr += "text "
            // don't want to print "real" and "complex" for text waves
            wantRC = 0
        endif
    elseif (ptype & 0x2000) // test for STRING bit set
        typeStr += "String "
        // don't want to print "real" and "complex" for strings
        wantRC = 0
    elseif (ptype & 4) // test for VARIABLE bit
        typeStr += "Variable "
    elseif (ptype & 0x200) // test for STRUCTURE bit
        typeStr += "Struct "
        wantRC = 0
    endif
    return typeStr
End

```

FunctionList

```
elseif (ptype & 0x400)                // test for FUNCREF bit
    typeStr += "FuncRef "
    wantRC = 0
endif
// print "real" and "complex" for numeric objects only
if (wantRC)
    if (ptype & 1)                    // test for COMPLEX bit
        typeStr += "cmplx "
    else
        typeStr += "real "
    endif
endif
if (ptype & 0x1000)                  // test for PASS BY REFERENCE bit
    typeStr += "reference "
endif
return typeStr
End
```

The **StringByKey** and **NumberByKey** functions.

StringByKey, **NumberByKey**, and **FunctionList** functions.

The **ModuleName Pragma** on page IV-40 and The **IndependentModule Pragma** on page IV-40.

FunctionList

FunctionList(*matchStr*, *separatorStr*, *optionsStr*)

The **FunctionList** function returns a string containing a list of built-in or user-defined function names satisfying certain criteria. This is useful for making a string to list functions in a pop-up menu control. Note that if the procedures need to be compiled, then **FunctionList** will not list user-defined functions.

Parameters

Only functions having names that match *matchStr* string are listed. Use "*" to match all names. See **WaveList** for examples.

The first character of *separatorStr* is appended to each function name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-144 for details on list processing).

Use *optionsStr* to further qualify the list of functions. *optionsStr* is a string containing keyword-value pairs separated by commas. Available options are:

KIND:*nk* *nk*=1: List built-in functions.
 nk=2: List normal and override user-defined functions.
 nk=4: List external functions (defined by an XOP).
 nk=8: List only curve fitting functions; must be summed with 1, 2, 4, or 16. For example, use 10 to list user-defined fitting functions.
 nk=16: Include static user-defined functions.

SUBTYPE:*typeName* Lists functions that have the type *typeName*. That is, you could use **ButtonControl** as *typeName* to list only functions that are action procedures for buttons.

VALTYPE:*nv* Restricts list to functions whose return type is a certain kind.

nv=1: Real-valued functions.
nv=2: Complex-valued functions.
nv=4: String functions.

Use a sum of these values to include more than one type. The return type is not restricted if this option is omitted.

NPARAMS:*np* Restricts the list to functions having exactly *np* parameters. Omitting this option lists functions having any number of parameters.

NINDVARS:*ni* Restricts the list to fitting functions for exactly *ni* independent variables. **NINDVARS** is ignored if you have not elected to list curve fitting functions using the **KIND** option. Functions for any number of independent variables are listed if the **NINDVARS** option is omitted.

- WIN:*windowTitle* Lists functions that are defined in the procedure window with the given title. "Procedure" is the title of the built-in procedure window.
- Note:** Because the *optionsStr* keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN:keyword must be the last one specified.
- WIN:*windowTitle* [*independentModuleName*] Lists functions that are defined in the named procedure window that belongs to the independent module *independentModuleName*. See **The IndependentModule Pragma** on page IV-40 for details. Requires `SetIgorOption IndependentModuleDev=1`, otherwise no functions are listed.
- Note:** The syntax is literal and strict: the window title must be followed by one space and a left bracket, followed directly by the independent module name and a closing right bracket.
- WIN:[*independentModuleName*] Lists functions that are defined in any procedure file that belongs to the named independent module.

Examples

To list user-defined fitting functions for two independent variables:

```
Print FunctionList("*", ";", "KIND:10,NINDVARS:2")
```

To list button-control functions that start with the letter *b* (note that button-control functions are user-defined):

```
Print FunctionList("b*", ";", "KIND:2,SUBTYPE:ButtonControl")
```

The IndependentModule Pragma on page IV-40.

For details on procedure subtypes, see **Procedure Subtypes** on page IV-149, as well as **Button**, **CheckBox**, **SetVariable**, and **PopupMenu**.

The **DisplayProcedure** operation and the **MacroList**, **OperationList**, **StringFromList**, and **WinList** functions.

FunctionPath

FunctionPath(*functionNameStr*)

The FunctionPath function returns a path to the file containing the named function. This is useful in certain specialized cases, such as if a function needs access to a lookup table of a large number of values.

The most likely use for this is to find the path to the file containing the currently running function. This is done by passing "" for *functionNameStr*, as illustrated in the example below.

The returned path uses Macintosh syntax regardless of the current platform. See **Path Separators** on page III-382 for details.

If the procedure file is a normal standalone procedure file, the returned path will be a full path to the file such as "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf".

If the function resides in the built-in procedure window the returned path will be ":Procedure". If the function resides in a packed procedure file, the returned path will be "<packed procedure window title>".

If FunctionPath is called when procedures are in an uncompiled state, it returns ":",.

Parameters

If *functionNameStr* is "", FunctionPath returns the path to the currently executing function or "" if no function is executing.

Otherwise FunctionPath returns the path to the named function or "" if no function by that name exists.

Examples

This example loads a lookup table into memory. The lookup table is stored as a wave in an Igor binary file.

```
Function LoadMyLookupTable()  
    String path
```

```
path = FunctionPath("") // Path to file containing this function.
if (CmpStr(path[0],":") == 0)
    // This is the built-in procedure window or a packed procedure
    // file, not a standalone file. Or procedures are not compiled.
    return -1
endif
// Create path to the lookup table file.
path = ParseFilePath(1, path, ":", 0, 0) + "MyTable.ibw"
String dfSave = GetDataFolder(1)
// A previously-created place to store my private data.
SetDataFolder root:Packages:MyData
// Load the lookup table.
LoadWave/O path
SetDataFolder dfSave
return 0
End
```

See Also

The **FunctionList** function.

gamma

gamma (num)

The gamma function returns the value of the gamma function of *num*. If *num* is complex, it returns a complex result. Note that the return value for *num* close to negative integers is NaN, not ±Inf.

See Also

The **gammln** function.

gammaInc

gammaInc(a, x [, upperTail])

The gammaInc function returns the value of the incomplete gamma function, defined by the integral

$$\Gamma(a, x) = \int_x^{\infty} e^{-t} t^{a-1} dt$$

If *upperTail* is zero, the limits of integration are 0 to x. If *upperTail* is absent, it defaults to 1, and the limits of integration are x to infinity, as shown. Note that **gammaInc(a, x) = gamma(a) - gammaInc(a, x, 0)**.

Defined for $x > 0$, $a \geq 0$ (*upperTail* = zero or absent) or $a > 0$ (*upperTail* = 0).

See Also

The **gamma**, **gammp**, and **gammq** functions.

gammaNoise

gammaNoise(a [, b])

The gammaNoise function returns a pseudo-random value from the gamma distribution

$$f(x) = \frac{x^{a-1} \exp\left(-\frac{x}{b}\right)}{b^a \Gamma(a)}, \quad x > 0, a > 0, b > 0$$

whose mean is ab and variance is ab^2 . For backward compatibility you can omit the parameter *b* in which case its value is set to 1. When $a \rightarrow 1$ gammaNoise reduces to **expnoise**.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

References

Marsaglia, G., and W. W. Tsang, *ACM*, 26, 363-372, 2000.

See Also

SetRandomSeed; Chapter III-12, **Statistics** for a function and operation overview.

gammln

gammln(*num* [, *accuracy*])

The **gammln** function returns the natural log of the gamma function of *num*, where *num* > 0. If *num* is complex, it returns a complex result. Optionally, *accuracy* can be used to specify the desired fractional accuracy. If *num* is complex, it returns a complex result. In this case, *accuracy* is ignored.

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7} , that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}}) / f_{\text{actual}}$ be less than 10^{-7} .

For backward compatibility, if you don't include *accuracy*, Igor uses older code that achieves an accuracy of about 2×10^{-10} .

With *accuracy*, newer code is used that is both faster and more accurate. The output has fractional accuracy better than 1×10^{-15} except for values near zero, where the absolute accuracy $(f_{\text{actual}} - f_{\text{returned}})$ is better than 2×10^{-16} .

The speed of calculation depends only weakly on accuracy. Higher accuracy is significantly slower than lower accuracy only for *num* between 6 and about 10.

See Also

The **gamma** function.

gammp

gammp(*a*, *x* [, *accuracy*])

The **gammp** function returns the regularized incomplete gamma function $P(a, x)$, where $a > 0$, $x \geq 0$. Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as **gammaInc**(*a*, *x*, 0) / **gamma**(*a*).

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7} , that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}}) / f_{\text{actual}}$ be less than 10^{-7} .

For backward compatibility, if you don't include *accuracy*, Igor uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

Igor will attempt to return a value having the full fractional accuracy you ask for, but is limited by double-precision calculations. That means that mostly the **gammp** function will have fractional accuracy better than about 10^{-15} , but this is not guaranteed, especially for extreme values of *a* and *x*.

See Also

The **gammaInc** and **gammq** functions.

gammq

gammq(*a*, *x* [, *accuracy*])

The **gammq** function returns the regularized incomplete gamma function $1 - P(a, x)$, where $a > 0$, $x \geq 0$. Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as **gammaInc**(*a*, *x*) / **gamma**(*a*).

Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to 10^{-7} , that means that you wish that the absolute value of $(f_{\text{actual}} - f_{\text{returned}}) / f_{\text{actual}}$ be less than 10^{-7} .

For backward compatibility, if you don't include *accuracy*, Igor uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

Igor will attempt to return a value having the full fractional accuracy you ask for, but is limited by double-precision calculations. That means that mostly the **gammq** function will have fractional accuracy better than about 10^{-15} , but this is not guaranteed, especially for extreme values of *a* and *x*.

See Also

The **gammaInc** and **gammp** functions.

Gauss

Gauss(x, xc, wx [, y, yc, wy [, z, zc, wz [, t, tc, wt]]])

The Gauss function returns a normalized Gaussian for the specified dimension.

$$\text{Gauss}(r, c, w) = \prod_{i=1}^n \frac{1}{w_i \cdot \sqrt{2\pi}} \exp\left\{-\frac{1}{2}\left(\frac{r_i - c_i}{w_i}\right)^2\right\}, \text{ where } n \text{ is the number of dimensions.}$$

Parameters

xc, *yc*, *zc*, and *tc* are the centers of the Gaussian in the X, Y, Z, and T directions, respectively.

wx, *wy*, *wz*, and *wt* are the widths of the Gaussian in the X, Y, Z, and T directions, respectively.

Note that w_i here is the standard deviation of the Gaussian. This is different from the width parameter in the gauss curve fitting function, which is $\text{sqrt}(2)$ times the standard deviation.

Note also that the Gauss function lacks the cross-correlation parameter that is included in the Gauss2D curve fitting function.

Examples

```
Make/n=100 eee=gauss(x,50,10)
Print area(eee,-inf,inf)
0.999999

Make/n=(100,100) ddd=gauss(x,50,10,y,50,15)
Print area(ddd,-inf,inf)
0.999137
```

Gauss1D

Gauss1D(w, x)

The Gauss1D function returns the value of a Gaussian peak defined by the coefficients in the wave *w*. The equation is the same as the Gauss curve fit:

$$w[0] = w[0] + w[1] \exp\left[-\left(\frac{x - w[2]}{w[3]}\right)^2\right].$$

Examples

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range:

```
Make/O/N=100 junkg // fake data wave
Setscale/I x -1,1,junkg
Display junkg
junkg = 1+2.5*exp(-(x-.5)/.3)^2)+gnoise(.1)
Duplicate/O junkg, junkgfit
junkgfit = NaN
AppendToGraph junkgfit
CurveFit gauss junkg[50,99] /D=junkgfit
// now extend the model trace
junkgfit = Gauss1D(w_coef, x)
```

See Also

The **CurveFit** operation.

Gauss2D

Gauss2D(w, x, y)

The Gauss2D function returns the value of a two-dimensional Gaussian peak defined by the coefficients in the wave *w*. The equation is the same as the Gauss2D curve fit:

$$w[0] + w[1] \exp\left[\frac{-1}{2(1 - w[6]^2)}\left(\left(\frac{x - w[2]}{w[3]}\right)^2 + \left(\frac{y - w[4]}{w[5]}\right)^2 - \frac{2w[6](x - w[2])(y - w[4])}{w[3]w[5]}\right)\right].$$

Examples

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range (watch out for the very long wave assignment to junkg2D):

```
Make/O/N=(100,100) junkg2D // fake data wave
Setscale/I x -1,1,junkg2D
```

```

Setscale/I y -1,1,junkg2D
Display; AppendImage junkg2D
//Caution! Next command wrapped to fit page:
junkg2D = -1 + 2.5*exp((-1/(2*(1-.4^2)))*((x-.1)/.2)^2+((y+.2)/.35)^2+2*.4*
          ((x-.1)/.2)*((y+.2)/.35)))
junkg2D += gnoise(.01)
Duplicate/O junkg2D, junkg2Dfit
junkg2Dfit = NaN
AppendMatrixContour junkg2Dfit
CurveFit gauss2D junkg2D[20,80][10,70] /D=junkg2Dfit[20,80][10,70]
// now extend the model trace
junkg2Dfit = Gauss2D(w_coef, x, y)

```

See Also

The **CurveFit** operation.

gcd

gcd(*A*, *B*)

The gcd function calculates the greatest common divisor of *A* and *B*, which are both assumed to be integers.

Examples

Compute least common multiple (LCM) of two integers:

```

Function LCM(a,b)
  Variable a, b
  return((a*b)/gcd(a,b))
End

```

GetAxis

GetAxis [/W=*winName* /Q] *axisName*

The GetAxis operation determines the axis range and sets the variables V_min and V_max to the minimum and maximum values of the named axis.

Parameters

axisName is usually "left", "right", "top" or "bottom", though it may also be the name of a free axis such as "VertCrossing".

Flags

/Q Prevents values of V_flag, V_min, and V_max from being printed in the history area. The results are still stored in the variables.

/W=*winName* Retrieves axis info from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

GetAxis sets V_min according to the bottom of vertical axes or left of horizontal axes and V_max according to the top of vertical axes or right of horizontal axes. It also sets the variable V_flag to 0 if the specified axis is actually used in the graph, or to 1 if it is not.

GetDataFolder

GetDataFolder(*mode*)

The GetDataFolder function returns a string describing the current data folder.

Details

If *mode*=1, GetDataFolder returns a string containing the full path to the current data folder. If *mode*=0, it returns just the name of the current data folder.

This can be used to save and restore the current data folder in a procedure.

GetDefaultFont

Examples

```
String savedDataFolder = GetDataFolder(1)           // save
SetDataFolder Root;; Variable/G gGlobalRootVar
SetDataFolder savedDataFolder                     // and restore
```

See Also

Chapter II-8, **Data Folders**.

GetDefaultFont

GetDefaultFont(*winName*)

The **GetDefaultFont** function returns a string containing the name of the default font for the named window or subwindow.

Parameters

If *winName* is null (that is, "") returns the default font for the experiment.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Only graph windows and the experiment as a whole have default fonts. If *winName* is the name of a window other than a graph (e.g., a layout), or if *winName* is not the name of any window, **GetDefaultFont** returns the experiment default font.

In user-defined functions, font names are usually evaluated at compile time. To use the output of **GetDefaultFont** in a user-defined function, you will usually need to build a command as a string expression and execute it with the **Execute** operation.

Examples

```
String fontName = GetDefaultFont("Graph0")
String command= "SetDrawEnv fname=\"\" + fontName + "\", save"
Execute command
```

See Also

The **GetDefaultFontSize**, **GetDefaultFontStyle**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

GetDefaultFontSize

GetDefaultFontSize(*graphNameStr*, *axisNameStr*)

The **GetDefaultFontSize** function returns the default font size of the graph or of the graph's axis (in points) in the specified window or subwindow.

Details

If *graphNameStr* is "" the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If *axisNameStr* is "", the font size of the default font for the graph is returned.

If named axis exists, the default font size for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

See Also

The **GetDefaultFont**, **GetDefaultFontStyle**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

GetDefaultFontStyle

GetDefaultFontStyle(*graphNameStr*, *axisNameStr*)

The **GetDefaultFontStyle** function returns the default font style of the graph or of the graph's axis in the specified window or subwindow.

Details

If *graphNameStr* is "" the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If *axisNameStr* is " ", the font style of the default font for the graph is returned.

If named axis exists, the default font style for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

The returned value is a binary coded number with each bit identifying one aspect of the font style as follows:

- bit 0: Bold.
- bit 1: Italic.
- bit 2: Underline.
- bit 3: Outline (*Macintosh only*).
- bit 4: Shadow (*Macintosh only*).
- bit 5: Condensed (*Macintosh only*).
- bit 6: Extended (*Macintosh only*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

See Also

The **GetDefaultFont**, **GetDefaultFontSize**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

GetDimLabel

GetDimLabel(*waveName*, *dimNumber*, *dimIndex*)

The GetDimLabel function returns a string containing the label for the given dimension or dimension element.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it returns the label for the entire dimension. If *dimIndex* is ≥ 0 , it returns the dimension label for that element of the dimension.

See Also

The **SetDimLabel** function. **Dimension Labels** on page II-93 for further usage details and examples.

GetFileFolderInfo

GetFileFolderInfo [*flags*] [*fileOrFolderNameStr*]

The GetFileFolderInfo operation returns information about a file or folder.

Parameters

fileOrFolderNameStr specifies the file (or folder) for which information is returned. It is optional if /P=*pathName* and /D are specified, in which case information about the directory associated with *pathName* is returned.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file from *fileOrFolderNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be examined. Use /D to select a folder.

Flags

- /D Uses the Select Folder dialog rather than Open File dialog when *pathName* and *fileOrFolderNameStr* do not specify an existing file or folder.
- /P=*pathName* Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.
- /Q No information printed to the history window.
- /Z Prevents procedure execution from aborting if the procedure tries to get information about a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

Variables

GetFileFolderInfo returns information in the following variables:

GetFileFolderInfo

V_flag	0: File or folder was found. -1: User cancelled the Open File dialog. >0: An error occurred, such as the specified file or folder does not exist.
S_path	File system path of the selected file.
V_isFile	1: <i>fileOrFolderNameStr</i> is a file.
V_isFolder	1: <i>fileOrFolderNameStr</i> is a folder.
V_isInvisible	1: File is invisible (<i>Macintosh</i>) or Hidden (<i>Windows</i>).
V_isReadOnly	Set if the file is locked (<i>Macintosh</i>) or is read-only (<i>Windows</i>). On <i>Windows</i> , V_isReadOnly is either 0 (unlocked) or 1 (locked). To set this manually, right-click the file and choose "Properties", then select or deselect the "read-only" checkbox. On <i>Macintosh</i> , V_isReadOnly is a bitmap of two settings: 0: Unlocked. 1: "Locked" with the Finder. Only files can be locked this way. You set this kind of locking with the Finder's Get Info window by selecting the "Locked" checkbox. 2: "File Locked" as with ResEdit. You can't set this kind of locking with the Finder, but applications can. See SetFileFolderInfo . 3: Both kinds of locking are set.
V_creationDate	Number of seconds since midnight on January 1, 1904 when the file or folder was first created. Use Secs2Date to get a text format date.
V_modificationDate	Number of seconds since midnight on January 1, 1904 when the file or folder was last modified. Use Secs2Date to get a text format date.
V_isAliasShortcut	1: File is an alias (<i>Macintosh</i>) or a shortcut (<i>Windows</i>) and S_aliasPath is also set.
If <i>fileOrFolderNameStr</i> refers to a file (not a folder), GetFileFolderInfo returns additional information in the following variables:	
S_aliasPath	Full path to the file or folder that is the source for an alias (<i>Macintosh</i>) or a shortcut (<i>Windows</i>). When the source is a folder, S_aliasPath ends with a ":" character.
V_isStationery	1: The stationery bit is set (<i>Macintosh</i>) or (<i>Windows</i>) the file type is one of the stationery file types (.pxt, .uxt, .ift).
S_fileType	Four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). On <i>Windows</i> , these codes are fabricated by translating from the equivalent file name extensions, such as .txt and .pxp.
S_creator	Four-character creator code, such as 'IGR0' (Igor Pro creator code). On <i>Windows</i> , S_creator is set to 'IGR0' if the file name extensions is one of those registered to Igor Pro, such as .pxp or .bwav (but not .txt). For other registered extensions, S_creator is set to the full file path of the registered application. Otherwise it is set to "".
V_logEOF	Number of bytes in the file data fork. For other forks, use Open/F and FStatus .
V_version	Version number of the file. On <i>Macintosh</i> , this is the value in the vers(1) resource. On <i>Windows</i> , a file version such as 3.10.2.1 is returned as 4.021: use S_fileVersion to avoid the problem of the second digit overflowing into the first digit. "0": File version can't be determined, or the file can't be examined because it is already open.
S_fileVersion	The file version as a string, added in Igor 5.02. On <i>Macintosh</i> , this is just a string representation of V_Version. On <i>Windows</i> , a file version such as 3.10.2.1 is returned as "3.10.2.1". "0": (<i>Macintosh</i>) file version can't be determined. "0.0.0.0": (<i>Windows</i>) file version can't be determined.

Details

You can change some of the file information by using **SetFileFolderInfo**.

Examples

Print the modification date of a file:

```
GetFileFolderInfo/Z "Macintosh HD:folder:infile.txt"
if( V_Flag == 0 && V_isFile )           // file exists
    Print Secs2Date(V_modificationDate,0), Secs2Time(V_modificationDate,0)
endif
```

Determine if a folder exists (easier than creating a path with NewPath and then using PathInfo):

```
GetFileFolderInfo/Z "Macintosh HD:folder:subfolder"
if( V_Flag && V_isFolder )
    Print "Folder Exists!"
endif
```

Find the source for a shortcut or alias:

```
GetFileFolderInfo/Z "Macintosh HD:fileThatIsAlias"
if( V_Flag && V_isAliasShortcut )
    Print S_aliasPath
endif
```

See Also

The **SetFileFolderInfo**, **PathInfo**, **ImageFileInfo**, and **FStatus** operations. The **IndexedFile**, **Secs2Date**, and **ParseFilePath** functions.

GetFormula

GetFormula(*objName*)

The GetFormula function returns a string containing the named object's dependency formula. The named object must be a wave, numeric variable or string variable.

Details

Normally an object will have an empty dependency formula and GetFormula will return an empty string (""). If you assign an expression to an object using the := operator or the SetFormula operation, the text on the right side of the := or the parameter to SetFormula is the object's dependency formula and this is what GetFormula will return.

Examples

```
Variable/G dependsOnIt
Make/O wave0 := dependsOnIt*2           //wave0 changes when dependsOnIt does
Print GetFormula(wave0)
```

Prints the following in the history area:

```
dependsOnIt*2
```

See Also

See **Dependency Formulas** on page IV-168, and the **SetFormula** operation.

GetIndependentModuleName

GetIndependentModuleName()

The GetIndependentModuleName function returns the name of the currently running Independent Module. If no Independent Module is running, it returns "ProcGlobal". See **The IndependentModule Pragma** on page IV-40.

GetIndexedObjName

GetIndexedObjName(*sourceFolderStr*, *objectType*, *index*)

The GetIndexedObjName function returns a string containing the name of the indexth object of the specified type in the data folder specified by the string expression.

Parameters

sourceFolderStr can be either ":" or "" to specify the current data folder. You can also use a full or partial data folder path. *index* starts from zero. If no such object exists a zero length string ("") is returned. *objectType* should be one of the following values:

<i>objectType</i>	What You Get
1	Waves
2	Numeric variables
3	String variables
4	Data folders

Examples

```
Function PrintAllWaveNames()  
    String objName  
    Variable index = 0  
    do  
        objName = GetIndexedObjName(":", 1, index)  
        if (strlen(objName) == 0)  
            break  
        endif  
        Print objName  
        index += 1  
    while(1)  
End
```

See Also

The **CountObjects** function, and Chapter II-8, **Data Folders**.

GetKeyState

GetKeyState(*flags*)

The GetKeyState function returns a bitwise numeric value that indicates the state of certain keyboard keys.

GetKeyState is normally called from a procedure that is invoked directly through a user-defined button or user-defined menu item. The procedure tests the state of one or more modifier keys and adjusts its behavior accordingly.

Another use for GetKeyState is to determine if Escape is pressed. This can be used to detect that the user wants to stop a procedure.

GetKeyState tests the keyboard at the time it is called. It does not tell you if keys were pressed between calls to the function. Consequently, when a procedure uses the escape key to break a loop, the user must press Escape until the running procedure gets around to calling the function.

Parameters

flags is reserved for future use and currently must be zero.

Details

When set, the return value is interpreted bitwise as follows:

- Bit 0: Command (*Macintosh*) or Ctrl (*Windows*) pressed.
- Bit 1: Option (*Macintosh*) or Alt (*Windows*) pressed.
- Bit 2: Shift pressed.
- Bit 3: Caps Lock pressed.
- Bit 4: Control pressed (*Macintosh only*).
- Bit 5: Escape pressed.

To test if a particular key is pressed, do a bitwise AND of the return value with the mask value 1, 2, 4, 8, 16, and 32 for bits 0 through 5 respectively. To test if a particular key and only that key is pressed compare the return value with the mask value.

On Macintosh, it is currently possible to define a keyboard shortcut for a user-defined menu item and then, in the procedure invoked by the keyboard shortcut, to use GetKeyState to test for modifier keys. This is not possible on Windows because the keyboard shortcut will not be activated if a modifier key not specified in the keyboard shortcut is pressed. It is also possible that this ability on Macintosh will be compromised by future operating system changes. On both operating systems, however, you can test for a modifier key when the user chooses a user-defined menu item or clicks a user-defined button using the mouse.

Examples

```

Function ShiftKeyExample()
    Variable keys = GetKeyState(0)
    if (keys == 0)
        Print "No modifier keys are pressed."
    endif
    if (keys & 4)
        if (keys == 4)
            Print "The Shift key and only the Shift key is pressed."
        else
            Print "The Shift key is pressed."
        endif
    endif
End
Function EscapeKeyExample()
    Variable keys
    do
        keys = GetKeyState(0)
        if ((keys & 32) != 0)           // User is pressing escape?
            break
        endif
    while(1)
End

```

Keyboard Shortcuts on page IV-99. **Setting Bit Parameters** on page IV-11 for details about bit settings.

GetLastUserMenuInfo**GetLastUserMenuInfo**

The GetLastUserMenuInfo operation sets variables in the local scope to indicate the value of the last selected user-defined menu item.

Details

GetLastUserMenuInfo creates and sets these special variables:

V_flag The kind of menu that was selected:

V_flag	Menu Kind
0	Normal text menu item, including Optional Menu Items (see page IV-92) and Multiple Menu Items (see page IV-93).
3	"*FONT*"
6	"*LINESTYLEPOP*"
7	"*PATTERNPOP*"
8	"*MARKERPOP*"
9	"*CHARACTER*"
10	"*COLORPOP*"
13	"*COLORTABLEPOP*"

See **Specialized Menu Item Definitions** on page IV-94 for details about these special user-defined menus.

V_value Which menu item was selected. The value also depends on the kind of menu the item was selected from:

V_flag	V_value meaning
0	Text menu item number (the first menu item is number 1).
3	Font menu item number (use S_Value, instead).

V_flag	V_value meaning
6	Line style number (0 is solid line)
7	Pattern number (1 is the first selection, a SW-NE light diagonal).
8	Marker number (1 is the first selection, the X marker).
9	Character as an integer, = char2num(S_Value). Use S_Value instead.
10	Color menu item (use V_red, V_green, and V_blue instead).
13	Color table list menu item (use S_Value instead).

S_value The menu item text, depending on the kind of menu it was selected from:

V_flag	S_value meaning
0	Text menu item text.
3	Font name or "default".
6	Name of the line style menu or submenu.
7	Name of the pattern menu or submenu.
8	Name of the marker menu or submenu.
9	Character as string.
10	Name of the color menu or submenu.
13	Color table name.

In the case of **Specialized Menu Item Definitions** (see page IV-94), S_value will be the title of the menu or submenu, etc.

V_red, V_green, V_blue

If a user-defined color menu ("*COLORPOP*" menu item) was chosen then these values hold the red, green, and blue values of the selected color. The values range from 0 to 65535.

Will be 0 if the last user-defined menu selection was not a color menu selection.

S_graphName, S_traceName

These are set only when any user-defined menu is chosen from a graph's trace contextual menu. (Menu "TracePopup" or Menu "AllTracesPopup" definitions).

Initially "" until a user-defined menu selection was made from one of these contextual menus, these are not reset for each user-defined menu selection.

S_graphName is the full host-child specification for the graph. If the graph is embedded into a host window, S_graphName might be something like "Panel0#G0". See **Subwindow Syntax** on page III-92.

S_traceName is name of the trace that was selected by the trace contextual menu, or "" if the AllTracesPopup menu was chosen. See **Subwindow Syntax** on page III-92.

Examples

A Multiple Menu Items menu definition:

```
Menu "Wave List", dynamic
    "Menu Item 1", <some command>
    "Menu Item 2", <some command>
    WaveList(" ", ";", ""), DoSomethingWithWave()
End
```

If the user selects one of the (many) menu items created by the "Wave List" menu item definition, the DoSomethingWithWave user function can call GetLastUserMenuInfo to determine which wave was selected:

```
Function DoSomethingWithWave()
    GetLastUserMenuInfo
    WAVE/Z selectedWave = $$S_value
    ...use selectedWave for something...
End
```

A trivial user-defined color menu definition:

```
Menu "Color"
  "*COLORPOP*", DoSomethingWithColor()
End
Function DoSomethingWithColor()
  GetLastUserMenuInfo
  ...do something with V_red, V_green, V_blue...
End
```

See **Specialized Menu Item Definitions** on page IV-94 for another color menu example.

A Trace contextual menu Items menu definition:

```
Menu "TracePopup", dynamic          // menu when a trace is right-clicked
  "_"                               // separator divides this from built-in menu items
  ExportTraceName(), ExportSelectedTrace()
End
Function/S ExportTraceName()
  GetLastUserMenuInfo              // only S_graphName, S_traceName are set.
  Return "Export "+S_traceName
End
Function ExportSelectedTrace()
  GetLastUserMenuInfo
  ...do something with S_graphName, S_traceName...
End
```

GetMarquee

GetMarquee [/K/W=*winName*/Z] [*axisName* [, *axisName*]]

The GetMarquee operation provides a way for you to use the marquee as an input mechanism in graphs and page layout windows. It puts information about the marquee into variables.

Parameters

If you specify *axisName* (allowed only for graphs) the coordinates are in axis units. If you specify an axis that does not exist, Igor generates an error.

If you specify only one axis then Igor sets only the variables appropriate to that axis. For example, if you execute "GetMarquee left" then Igor sets the V_bottom and V_top variables but does *not* set V_left and V_right.

Flags

/K	Kills the marquee. Usually you will want to kill the marquee when you call GetMarquee, so you should use the /K flag. This is modeled after what happens when you create a marquee in a graph and then choose Expand from the Marquee menu. There may be some situations in which you want the marquee to persist. Igor also automatically kills the marquee anytime the window containing the marquee is deactivated, including when a dialog is summoned.
/W= <i>winName</i>	Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Z	No runtime error generated if the target window isn't a graph or layout, but V_flag will be zero. /Z does not prevent other kinds of problems from generating a runtime error.

Details

GetMarquee is intended to be used in procedures invoked through user menu items added to the graph Marquee menu and the layout Marquee menu.

GetMarquee sets the following variables and strings:

V_flag	0: There was no marquee when GetMarquee was invoked. 1: There was a marquee when GetMarquee was invoked.
V_left	Marquee left coordinate.

GetMarquee

V_right	Marquee right coordinate.
V_top	Marquee top coordinate.
V_bottom	Marquee bottom coordinate.
S_marqueeWin	Name of window containing the marquee, or "" if no marquee. If subwindow, subwindow syntax will be used.

When called from the command line, GetMarquee sets global variables and strings in the current data folder. When called from a procedure, it sets local variables and strings.

In addition, creating, adjusting, or removing a marquee may set additional marquee global variables (see the **Marquee Globals** section, below).

The target window must be a layout or a graph. Use /Z to avoid generating a runtime-error (V_flag will be 0 if the target window was not a layout or graph).

If the target is a layout then Igor sets the variables in units of points relative to the top/left corner of the paper.

If the target is a graph then Igor sets V_left and V_right based on the specified horizontal axis or uses screen units (points, not pixels) relative to the top left of the graph area if no horizontal axis was specified. Similar considerations apply for V_bottom and V_top which are set if a vertical axis was specified.

If there is no marquee when you invoke GetMarquee then Igor sets V_left, V_top, V_right, V_bottom based on the last time the marquee was active.

GetMarquee Example

```
Menu "GraphMarquee"
  "Print Marquee Coordinates", PrintMarqueeCoords()
End
Function PrintMarqueeCoords()
  GetMarquee left, bottom
  if (V_flag == 0)
    Print "There is no marquee"
  else
    printf "marquee left in bottom axis terms: %g\r", V_left
    printf "marquee right in bottom axis terms: %g\r", V_right
    printf "marquee top in left axis terms: %g\r", V_top
    printf "marquee bottom in left axis terms: %g\r", V_bottom
  endif
End
```

You can run this procedure by putting it into the procedure window, making a marquee in a graph, clicking in the marquee and choosing Print Marquee Coordinates:

The procedure calls GetMarquee to set the local marquee variables and then prints their values in the history area:

```
•PrintMarqueeCoords()
  marquee left in bottom axis terms: 32.1149
  marquee right in bottom axis terms: 64.7165
  marquee top in left axis terms: 0.724075
  marquee bottom in left axis terms: -0.131061
```

Marquee Globals

You can cause Igor to update global marquee variables whenever the user adjusts the marquee (without the need for you to invoke GetMarquee) by creating a global variable named V_marquee in the root data folder:

Variable/G root:V_marquee = 1 //Creates V_marquee and sets bit 0 only

When the user adjusts the marquee Igor checks to see if root:V_marquee exists and which bits are set, and updates (and creates if necessary) these globals:

Variable/G root:V_left	Marquee left coordinate.
Variable/G root:V_right	Marquee right coordinate.
Variable/G root:V_top	Marquee top coordinate.
Variable/G root:V_bottom	Marquee bottom coordinate.
String/G root:S_marqueeWin	Name of window that contains marquee, or "" if no marquee. Set only if root:V_Marquee has bit 15 (0x8000) set.

Unlike the local variables, for graphs these global variables are never in points. Root:V_left and V_right will be axis coordinates based on the first bottom axis created for the graph (if none, then for the first top axis). The axis creation order is the same as is returned by **AxisList**. Similarly, root:V_top and root:V_bottom will be axis coordinates based on the first left axis or the first right axis.

Igor examines the global root:V_marquee for bitwise flags to decide which globals to update, and when:

root:V_marquee Bit Meaning	Bit Number	Bit Value
Update global variables for graph marquees	0	1
Update global variables for layout marquees	2	4
Update S_marqueeWin when updating global variables	15	0x8000

Marquee Globals Example

By creating the global variable root:V_marquee this way:

```
Variable/G root:V_marquee = 1 + 4 + 0x8000
```

whenever the user creates, adjusts, or removes a marquee in any graph or layout Igor will create and update the global root:V_left, etc. coordinate variables and set the global string root:S_marqueeWin to the name of the window which has the marquee in it. When the marquee is removed, root:S_marqueeWin will be set to "".

This mechanism does neat things by making a **ValDisplay** or **SetVariable** control depend on any of the globals. See the Marquee Demo experiment in the Examples:Feature Demos folder for an example.

You can also cause a function to run whenever the user creates, adjusts, or removes a marquee by setting up a dependency formula using **SetFormula** to bind one of the marquee globals to one of the function's input arguments:

```
Variable/G root:dependencyTarget
SetFormula root:dependencyTarget, "MyMarqueeFunction(root:S_marqueeWin)"
Function MyMarqueeFunction(marqueeWindow)
    String marqueeWindow          // this will be root:S_marqueeWin
    if( strlen(marqueeWindow) )
        NVAR V_left= root:V_left, V_right= root:V_right
        NVAR V_top= root:V_top, V_bottom= root:V_bottom
        Printf marqueeWindow + " has a marquee at: "
        Printf "%d, %d, %d, %d\r", V_left, V_right, V_top, V_bottom
    else
        Print "The marquee has disappeared."
    endif
    return 0                      // return value doesn't really matter
End
```

The **SetMarquee** and **SetFormula** operations. **Setting Bit Parameters** on page IV-11 for information about bit settings.

GetRTErrors

GetRTErrors(clearitFlag)

The GetRTErrors function helps with debugging user-defined functions. It returns a nonzero number if an error has occurred during execution of a user-defined function. A message with information about the error can be retrieved using **GetRTErrMessage**.

GetRTErrorMessage

If *clearitFlag* is nonzero, the error is cleared, allowing execution of the function to continue. This is useful if you wish to attempt to recover from the error. GetRTErrorMessage must be called before calling GetRTErrror with nonzero *clearitFlag*.

An important use for GetRTErrror is to track down the cause and the point of occurrence of an error that produces an error alert during function execution. This might be done as follows:

```
... some function code
if (GetRTErrror(0))
    print "Error in function MyFunc"
    print GetRTErrorMessage()
endif
```

GetRTErrorMessage

GetRTErrorMessage()

In a user function, GetRTErrorMessage returns a string containing the name of the operation that caused the error, a semicolon, and an error message explaining the cause of the error. This is the same information that appears in the alert dialog displayed. If no error has occurred, the string will be of zero length. GetRTErrorMessage must be called before the error is cleared by calling GetRTErrror with a nonzero argument.

See also

The **GetRTErrror** function.

GetRTStackInfo

GetRTStackInfo(*selector*)

The GetRTStackInfo function returns information about “runtime stack” (the chain of macros and functions that are executing).

Details

If *selector* is 0, GetRTStackInfo returns a semicolon-separated list of the macros and procedures that are executing. This list is the same you would see in the debugger’s stack list.

The currently executing macro or function is the last item in the list, the macro or function that started execution is the first item in the list.

If *selector* is 1, it returns the name of the currently executing function or macro.

If *selector* is 2, it returns the name of the calling function or macro.

If *selector* is 3, GetRTStackInfo returns a semicolon-separated list of routine names, procedure file names and line numbers. This is intended for advanced debugging by advanced programmers only.

For example, if RoutineA in procedure file ProcA.ipf calls RoutineB in procedure file ProcB.ipf, and RoutineB calls GetRTStackInfo(3), it will return:

```
RoutineA,ProcA.ipf,7;RoutineB,ProcB.ipf,12;
```

The numbers 7 and 12 would be the actual numbers of the lines that were executing in each routine. Line numbers are zero-based.

GetRTStackInfo does not work correctly with string macros executed via the Execute operation.

In future versions of Igor, *selector* may request other kinds of information.

Examples

```
Function Called()
    Print "Called by " + GetRTStackInfo(2) + "()"
    Print "Routines in calling chain: " + GetRTStackInfo(0)
End
Function Calling()
    Called()
End
Macro StartItUp()
    Calling()
End
```

Executing on the Command line:

```
·StartItUp()
  Called by Calling()
  Routines in calling chain: StartItUp;Calling;Called;
```

See Also

StringFromList, **ItemsInList**, and **GetRTError** functions. **The Stack and Variables Lists** on page IV-157.

GetScrapText

GetScrapText ()

The **GetScrapText** function returns a string containing any plain text on the Clipboard (aka “scrap”). This is the text that would be pasted into a text document if you used Paste in the Edit menu.

See Also

The **PutScrapText** and **LoadPICT** operations.

GetSelection

GetSelection winType, winName, bitflags

The **GetSelection** operation returns information about the current selection in the specified window.

Parameters

winType is one of the following keywords:

graph, *panel*, *table*, *layout*, *notebook*

winName is the name of a window of the specified type.

bitflags is a bitwise parameter that is used in different ways for different window types, as described in **Details**. You should use 0 for undefined bits. **Setting Bit Parameters** on page IV-11 for further details about bit settings.

Details

For all window types, **GetSelection** sets *V_flag*:

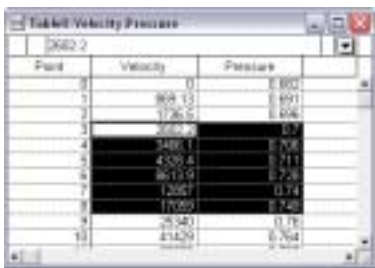

- | | | |
|---------------|----|---|
| <i>V_flag</i> | 0: | No selection when GetSelection was invoked. |
| | 1: | There was a selection when GetSelection was invoked. |

Here is a description of what **GetSelection** does for each window type:

<i>winType</i>	<i>bitFlags</i>	Action
graph		Does nothing.
panel		Does nothing.
table	1	Sets <i>V_startRow</i> , <i>V_startCol</i> , <i>V_endRow</i> , and <i>V_endCol</i> based on the selected cells in the table. The top/left cell, not including the Point column, is (0, 0).
	2	Sets <i>S_selection</i> to a semicolon-separated list of column names.
	4	Sets <i>S_dataFolder</i> to a semicolon-separated list of data folders, one for each column.
layout	2	Sets <i>S_selection</i> to a semicolon separated list of selected objects in the layout layer (not any drawing layers). <i>S_selection</i> will be "" if no objects are selected.
notebook	1	Sets <i>V_startParagraph</i> , <i>V_startPos</i> , <i>V_endParagraph</i> , and <i>V_endPos</i> based on the selected text in the notebook.
	2	Sets <i>S_selection</i> to the selected text.

Examples

Make a table named “Table0” with some columns, and select some combination of rows and columns:

Point	Velocity	Pressure
0	0	0.890
1	868.13	0.891
2	1736.5	0.896
3	2604.9	0.9
4	3486.1	0.906
5	4369.4	0.911
6	5251.9	0.926
7	6135.7	0.94
8	7020	0.949
9	7905.1	0.96
10	8790.5	0.968

and execute these commands in a procedure or in the command line:

```
GetSelection table, Table0, 3
Print V_flag, V_startRow, V_startCol, V_endRow, V_endCol
Print S_selection
```

This will print the following in the history area:

```
1 3 0 8 1
Velocity.d;Pressure.d;
```

GetUserData

GetUserData(winName, objID, userdataName)

The GetUserData function returns a string containing the user data for a window or subwindow. The return string will be empty if no user data exists.

Parameters

winName may specify a window or subwindow name. Use "" for the top window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

objID is a string specifying the name of a control. Use "" for a window or subwindow.

userdataName is the name of the user data or "" for the default unnamed user data.

See Also

The **ControlInfo**, **GetWindow**, and **SetWindow** operations.

GetWavesDataFolder

GetWavesDataFolder(waveName, kind)

The GetWavesDataFolder function returns a string containing the name of a data folder containing the wave named by *waveName*. Variations on the theme are selected by *kind*.

The most common use for this is in a procedure, when you want to create a wave or a global variable in the data folder containing a wave passed as a parameter.

Details

<i>kind</i>	GetWavesDataFolder Returns
0	Only the name of the data folder containing <i>waveName</i> .
1	Full path of data folder containing <i>waveName</i> , without wave name.
2	Full path of data folder containing <i>waveName</i> , including possibly quoted wave name.
3	Partial path from current data folder to the data folder containing <i>waveName</i> .
4	Partial path including possibly quoted wave name.

Kinds 2 and 4 are especially useful in creating command strings to be passed to **Execute**.

Examples

```
Function DuplicateWaveInDataFolder(w)
    Wave w
    String dfSav = GetDataFolder(1)
    SetDataFolder GetWavesDataFolder(w,1)
```

```

Duplicate/O w, $(NameOfWave(w) + "_2")
SetDataFolder dfSav
End

```

See Also

Chapter II-8, **Data Folders**.

GetWindow

GetWindow *winName*, *keyword*

The GetWindow operation provides information about the named window or subwindow. Information is returned in variables, strings, and waves.

Parameters

winName can be the name of graph, table, panel, page layout, notebook, or any subwindow. It can also be the title of a procedure window or one of these four special keywords:

kwTopWin	Specifies the topmost graph, table, panel, page layout, or notebook window.
kwCmdHist	Specifies the command history window.
kwFrameOuter	Specifies the “frame” or “application” window that Igor Pro has only under Windows. This is the window that contains Igor’s menus and status bar.
kwFrameInner	Specifies the inside of the same “frame” window under Windows. This is the window that all other Igor windows are inside.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Only one of the following keywords may follow *winName*. The keyword chosen determines the information stored in the output variables:

activeSW	Stores the window “path” of currently active subwindow in S_Value. See Subwindow Syntax on page III-92 for details on the window hierarchy.
gsize	Reads graph outer dimensions into V_left, V_right, V_top, and V_bottom in local coordinates. This includes axes but not the tool bar, control bar, or info panel. Dimensions are in points.
gsizeDC	Same as gsize but dimensions are in device coordinates (pixels).
hide	Sets V_Value bit 0 if window or subwindow is hidden. Sets bit 1 if the host window is minimized.
hook	Copies name of window hook function to S_value. See SetWindow and the Unnamed Hooks section.
hook(<i>hName</i>)	For the given named hook <i>hName</i> , copies name of window hook function to S_value. See SetWindow and the Named Hooks section.
logicalpapersize	Returns logical paper size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points. If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page. V_left and V_top are 0 and correspond to the left top corner of the physical page. On the Macintosh, using a Scale of 50% multiplies all of these dimensions by 2.
logicalprintablesizesize	Returns logical printable size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points. If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page minus the margins. V_left and V_top are the number of points from the left top corner of the physical page to the left top corner of the printable area of page. On the Macintosh, using a page setup scale of 50% multiplies all of these dimensions by 2.
needUpdate	Sets V_Value to 1 if window or subwindow is marked as needing an update.
note	Copies window note to S_value.
psize	Reads graph plot area dimensions (where the traces are) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.
psizeDC	Same as psize but dimensions are in device coordinates (pixels).

GetWindow

title	Gets the title (set by as <i>titleStr</i> with NewPanel, Display, etc., or by the Window Control dialog) and puts it into S_value.
userdata	Returns the primary (unnamed) user data for a window in S_value. Use GetUserData to obtain any named user data.
wavelist	Creates a three-column text wave called W_WaveList containing a list of waves used in the graph in <i>winName</i> . Each wave occupies one row in W_WaveList. This list includes all waves that can be in a graph, including the data waves for contour plots and images.
wsiz	Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. For subwindows, values are local coordinates in the host.
wsizDC	Same as wsiz but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle.
wsizOuter	Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. Dimensions are for the entire window including any frame and title bar. For subwindows, values are for the host window.
wsizOuterDC	Same as wsizOuter but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle, so V_top will be negative for a window with a title bar. V_left will be negative for windows with a frame; windows on Macintosh OS X have no frame, so V_left will be zero.

Details

The wsiz parameter is appropriate for all windows.

The gsize, psize, and wavelist parameters are appropriate only for graph windows.

The logicalpapersize and logicalprintablesiz parameters are appropriate for all printable windows (not panels).

kwCmdHist, kwFrameInner, and kwFrameOuter may be used with only the wsiz keyword.

On Windows computers, kwFrameInner and kwFrameOuter return coordinates into V_left, V_right, V_top, and V_bottom. On the Macintosh, they always return 0 (because Igor has no frame on the Macintosh).

kwFrameOuter coordinates are the location of the outer edges of Igor's application window, expressed in screen (pixel) coordinates suitable for use with **MoveWindow/F** to restore, minimize, or maximize the Igor application window.

If Igor is currently minimized, kwFrameOuter returns 0 for all values. If maximized, it returns 2 for all values. Otherwise, the screen (pixel) coordinates of the frame are returned in V_left, V_right, V_top, and V_bottom. This is consistent with **MoveWindow/F**.

kwFrameInner coordinates, however, are the location of the inner edges of the application window, expressed in Igor window coordinates (points) suitable for positioning graphs and other windows with **MoveWindow**.

If Igor is currently minimized, `kwFrameInner` returns the inner frame coordinates Igor would have if Igor were “restored” with `MoveWindow/F 1,1,1,1`.

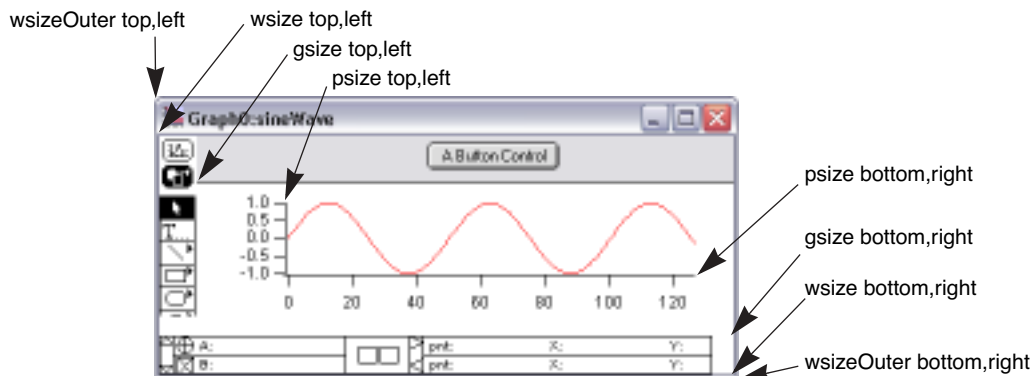

`V_left` and `V_top` will always both be 0, and `V_Bottom` and `V_Right` will be the maximum visible (or potentially visible) window (not screen) coordinates in points.

`winName` can be the title of a procedure window. If the title contains spaces, use:

`GetWindow $"Title With Spaces" wsize`

However, if another window has a name which matches the given procedure window title, that window’s properties are returned instead of the procedure window.

“Local coordinates” are relative to the top left of the graph area, regardless of where that is on the screen or within the graph window. All dimensions are reported in units of points (1/72 inch) regardless of screen resolution. On the Macintosh, this is the same as screen pixels.

The format of `W_WaveList`, created with the `wavelist` keyword, is as follows:

Column 1	Column 2	Column 3
Wave name	partial path to the wave	special ID number

The wave name in column 1 is simply the name of the wave with no path. It may be the same as other waves in the list, if there are waves from different data folders.

The partial path in column 2 includes the wave name and can be used with the `$` operator to get access to the wave.

The special ID number in column 3 has the format `##<number>##`. A version of the recreation macro for the graph can be generated that uses these ID numbers instead of wave names (see the **WinRecreation** function). This makes it relatively easy to find every occurrence of a particular wave using a function like **strsearch**.

For instance, executing these commands:

```
NewDataFolder/S Folder1
Make/N=10 Wave1=x
SetDataFolder ::
NewDataFolder/S Folder2
Make/N=10 Wave1=sqrt(x)
SetDataFolder ::
Display :Folder1:wave1 vs :Folder2:wave1
```

Makes a graph similar to this:

Executing these commands:

```
GetWindow kwTopWin, wavelist
Edit W_WaveList
```

makes a table similar to this:

Examples

These commands draw a red foreground rectangle framing the printable area of a page layout window:

```
GetWindow Layout0 logicalpapersize
DoWindow/F Layout0
SetDrawLayer/K userFront
SetDrawEnv linefgc=(65535,0,0), fillpat=0           // transparent fill
DrawRect V_left+1, V_top+1, V_right-1, V_bottom-1
```

See Also

The **SetWindow**, **GetUserData**, and **MoveWindow** operations.

hnoise

hnoise(num [, RNG])

The hnoise function returns a random value from a Gaussian distribution such that the standard deviation of an infinite number of such values would be *num*.

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never get the same sequence twice. If you want repeatable “random” numbers, use **SetRandomSeed**.

The Gaussian distribution is achieved using a Box-Muller transformation of uniform random numbers.

The optional parameter *RNG* selects one of two different pseudo-random number generators used to create the uniformly-distributed random numbers used as the input to the Box-Muller transformation. If omitted, the default is 1. The *RNG*’s are:

<i>RNG</i>	Description
1	Linear Congruential generator by L’Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <i>Numerical Recipes</i> (2nd edition) as the function <code>ran2 ()</code> . This RNG has nearly 2^{32} distinct values and the sequence of random numbers has a period in excess of 10^{18} .
2	Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of $2^{19937}-1$.

See Also

The **SetRandomSeed** operation and the **hnoise** function.

Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

Details about the Mersene Twister are in:

Matsumoto, M., and T. Nishimura, Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator, *ACM Trans. on Modeling and Computer Simulation*, 8, 3-30, 1998.

More information is available online at: <<http://www.math.keio.ac.jp/~matumoto/emt.html>>

Graph

Graph

Graph is a procedure subtype keyword that identifies a macro as being a graph recreation macro. It is automatically used when Igor creates a window recreation macro for a graph. See **Procedure Subtypes** on page IV-149 and **Saving and Recreating Graphs** on page II-279 for details.

GraphMarquee

GraphMarquee

GraphMarquee is a procedure subtype keyword that puts the name of the procedure in the graph Marquee menu. See **Marquee Menu as Input Device** on page IV-115 for details.

GraphNormal

GraphNormal [/W=*winName*]

The GraphNormal operation returns the target or named graph to the normal mode, exiting any drawing mode that it may be in.

You would usually enter normal mode by choosing ShowTools from the Graph menu and clicking the crosshair tool.

Flags

/W=winName Reverts the named graph window. This must be the first flag specified when used in a Proc or Macro or on the command line.

See Also

The **GraphWaveDraw** and **GraphWaveEdit** operations.

GraphStyle

GraphStyle

GraphStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Graph dialog and in the Graph Macros menu. See **Graph Style Macros** on page II-280 for details.

GraphWaveDraw

GraphWaveDraw [*flags*] [*yWaveName*, *xWaveName*]

The GraphWaveDraw operation initiates drawing a curve composed of *yWaveName* vs *xWaveName* in the target or named graph. The user draws the curve using the mouse, and the values are stored in a pair of waves as XY data.

Normally, you would initiate drawing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveDraw.

Parameters

yWaveName and *xWaveName* will contain the y and x values of the curve drawn by the user with the mouse.

If *yWaveName* and *xWaveName* do not already exist, they are created with two points which are initially set to NaN (Not a Number) and appended to the target.

If *yWaveName* and *xWaveName* already exist, an error is generated unless the */O* (overwrite) flag is present. If */O* is present, the waves are re-created — with two points which are initially set to NaN — and appended to the target if they are not already in it.

If *yWaveName* and *xWaveName* are omitted then waves called *W_YPolyn* and *W_XPolyn* are created with two points set to NaN and appended to the target (*n* is some digit, so Igor might create a wave named *W_YPoly0*, for example).

Flags

<i>/F[=f]</i>	Initiates freehand drawing. In normal drawing, you click where you want a data point. In freehand drawing, you click once and then draw with the mouse button held down. If present, <i>f</i> specifies the smoothing factor. Max value is 8 (which is really slow), min value is 0 (default). The drawing tools use a value of 3 which is the recommended value.
<i>/L/R/B/T</i>	Specifies which axes to use (Left, Right, Bottom, Top). Bottom and Left axes are used by default. Can specify free axes using <i>/L=axis name</i> type notation. See AppendToGraph for details. If necessary, the specified axes will be created. If an axis is created its range is set to -1 to 1.
<i>/M</i>	Specifies that the curve being edited must be monotonic in the X dimension. The user is not allowed drag points so that they cross horizontally.
<i>/O</i>	Overwrites <i>yWaveName</i> and <i>xWaveName</i> if they already exist.

GraphWaveEdit

/W=winName Draws in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Once drawing starts no other user actions are allowed.

In normal mode, drawing stops when you double-click or when you click the first point (in which case the last point is set equal to the first point). When drawing finishes, the edit mode is entered.

In freehand mode, drawing stops when the mouse is released or when 10000 points have been drawn.

If */O* is used and the waves are already on the graph then the first instance on the graph will be used even if they use a different pair of axes than specified.

See Also

The **GraphNormal** and **GraphWaveEdit** operations.

GraphWaveEdit

GraphWaveEdit [*flags*] *traceName*

The GraphWaveEdit operation initiates editing a wave trace in a graph. The wave trace must already be in the graph.

Normally, you would initiate editing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveEdit.

Parameters

traceName is a wave name, optionally followed by the # character and an instance number: "myWave#1" is the *second* instance of myWave appended to the graph ("myWave" is the first).

If *traceName* is omitted then you get to pick the wave trace to edit by clicking it.

Flags

/M Specifies that the edited trace must be monotonic in the X dimension. You cannot drag points so that they cross horizontally.

/NI Suppresses automatic new point insertion when clicking between points.

/T=t Sets the trace mode.

t=0: Lines and small square markers (default).

t=1: User settings unchanged.

/W=winName Edits traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The GraphWaveEdit operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **GraphNormal** and **GraphWaveDraw** operations.

Grep

Grep [*flags*][*srcFileStr*][*srcTextWaveName*][*as* [*destFileOrFolderStr*]
[*destTextWaveName*]]

The Grep operation copies lines matching a search expression from a file on disk, the Clipboard, or rows from a text wave to a new or existing file, an existing text wave, the History area, the Clipboard, or to S_value as a string list.

Source Parameters

The optional *srcFileStr* can be

- The full path to the file to copy lines from (in which case /P is not needed).
- The partial path relative to the folder associated with *pathName*.
- The name of a file in the folder associated with *pathName*.
- “Clipboard” to read lines of text from the Clipboard (in which case /P is ignored).

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

The optional *srcTextWaveName* is the name or path to a text wave.

Only one of *srcFileStr* or *srcTextWaveName* may be specified. If neither is specified then an Open File dialog is presented allowing you to specify a source file.

Destination Parameters

The optional *destFileOrFolderStr* can be

- The name of (or path to) an existing folder when /D is specified.
- The name of (or path to) a possibly existing file.
- “Clipboard”, in which case the matching lines are copied to the Clipboard (and /P and /D are ignored). The text can be retrieved with the **GetScrapText** function.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If /D is specified, the source file is created inside the folder using the source file name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

The optional *destTextWaveName* is the name or path to an existing text wave. It may be the same wave as *srcTextWaveName*.

Only one of *destFileOrFolderStr* or *destTextWaveName* may be specified.

If no destination file or text wave is specified then matching lines are printed in the history area, unless the /Q flag is specified, in which case the matching lines aren't printed or copied anywhere (though the output variables are still set).

Use /LIST to set S_value to a string list containing the matching lines or rows.

Use /INDX to create a wave W_index containing the zero-based row or line number where matches were found.

Parameter Details

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single path separators. See **MoveFolder's** Details section.

Flags

- | | |
|----------------|---|
| /A | Appends matching lines to the destination file, creating it if necessary, appends text to the Clipboard if the <i>destFileOrFolderStr</i> is “Clipboard”, or appends rows to the destination text wave. Has no effect on output to the History area. |
| /D | Interprets <i>destFileOrFolderStr</i> as the name of (or path to) an existing folder (or directory). Without /D, <i>destFileOrFolderStr</i> is the name of (or path to) a file. It is ignored if the destination is a text wave, the Clipboard, or the History area.
If <i>destFileOrFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> . |
| /DCOL={colNum} | Useful only when the destination is <i>destTextWaveName</i> .
Copies matching lines of text from the source file, Clipboard, or <i>srcTextWaveName</i> to column <i>colNum</i> of <i>destTextWaveName</i> , with any terminator characters removed.
The default when the source is a file or the Clipboard is /DCOL={0}, which copies matching lines into the first column of <i>destTextWaveName</i> . |

	<p>The default when the source is <i>srcTextWaveName</i> is to copy each column of a matched row to the corresponding column in <i>destTextWaveName</i>.</p> <p>/DCOL must be used with the /A flag, otherwise the destination wave will have only 1 column.</p>
/DCOL={ <i>colNum</i> [<i>delimStr</i> , ...]}	<p>Useful only when the source is <i>srcTextWaveName</i> and the destination is a file, the Clipboard, History area, or S_value.</p> <p>Copies multiple columns in any order from matching rows of <i>srcTextWaveName</i> to the destination file, Clipboard, History area, or S_value.</p> <p>Construct the line by appending the contents of the numbered column and the <i>delimStr</i> parameters in the order specified. The output line is terminated as described in Line Termination.</p>
/E= <i>regExprStr</i>	<p>Specifies the Perl-compatible regular expression string. A line must match the regular expression to be copied to the output file. See Regular Expressions.</p> <p><i>Multiple /E flags may be specified</i>, in which case a line is copied only if it matches every regular expression.</p>
/E={ <i>regExprStr</i> , <i>reverse</i> }	<p>Specifies the Perl-compatible regular expression string, <i>regExprStr</i>, for which the sense of the match can be changed by <i>reverse</i>.</p> <p><i>reverse</i>=1: Matching expressions are taken to not match, and vice versa. For example, use /E={ "CheckBox" , 1 } to list all lines that do not contain "CheckBox".</p> <p><i>reverse</i>=0: Same as /E=<i>regExprStr</i>.</p>
/GCOL= <i>grepCol</i>	<p>Greps the specified column of <i>srcTextWaveName</i>, which is a two-dimensional text wave. The default search is on the first column (<i>grepCol</i>=0). Use <i>grepCol</i>=-1 to match against any column of <i>srcTextWaveName</i>.</p> <p>Does not apply if the source is a file or Clipboard.</p>
/I	<p>Requires interactive searching even if <i>srcFileStr</i> and <i>destFileOrFolderStr</i> are specified and if the source file exists. Same as /I=3.</p>
/I= <i>i</i>	<p>Specifies the degree of file search interactivity with the user.</p> <p><i>i</i> =0: Default; interactive only if <i>srcFileStr</i> is not specified or if the source file is missing. Same as if /I were not specified.</p> <p>Note: This is different behavior than other commands such as CopyFile.</p> <p><i>i</i> =1: Interactive even if <i>srcFileStr</i> is specified and the source file exists.</p> <p><i>i</i> =2: Interactive even if <i>destFileOrFolderStr</i> is specified.</p> <p><i>i</i> =3: Interactive even if <i>srcFileStr</i> is specified, the source file exists, and <i>destFileOrFolderStr</i> is specified.</p>
/INDX	<p>Creates in the current data folder an output wave W_Index containing the line numbers (or row numbers) where matching lines were found. If this is the only output you need, also use the /Q flag.</p>
/LIST[= <i>listSepStr</i>]	<p>Creates in the current data folder an output string variable S_value containing a semicolon-separated list of the matching lines. If <i>listSepStr</i> is specified, then it is used to separate the list items. See StringFromList for details on string lists. If this is the only output you need, also use the /Q flag.</p>
/M= <i>messageStr</i>	<p>Specifies the prompt message in any Open File dialog. If /S is not specified, then <i>messageStr</i> will be used for both the Open File and Save File dialogs.</p>
/O	<p>Overwrites any existing destination file.</p>
/P= <i>pathName</i>	<p>Specifies the folder containing the source file or the folder into which the file is copied. <i>pathName</i> is the name of an existing symbolic path.</p> <p>Both <i>srcFileStr</i> and <i>destFileOrFolderStr</i> must be either simple file or folder names, or paths relative to the folder specified by <i>pathName</i>.</p>
/Q	<p>Prevents printing results to an output file, text wave, History, or Clipboard. Use /Q to check for a match to <i>regExprStr</i> by testing the value of V_flag, V_value, S_value (/LIST), or W_Index (/INDX) without generating any other matching line output.</p> <p>Note: When using /Q neither <i>destFileOrFolderStr</i> nor <i>destTextWaveName</i> may be specified.</p>

/S=saveMessageStr Specifies the prompt message in any Save File dialog.

/T=termcharStr Specifies the terminator character.

<i>termcharStr</i>	Terminator
<i>/T=(num2char(13))</i>	Carriage return (CR, ASCII code 13).
<i>/T=(num2char(10))</i>	Linefeed (LF, ASCII code 10).
<i>/T=" ; "</i>	Semicolon.
<i>/T=" "</i>	Null (ASCII code 0).

See **Line Termination** for the default behavior of the terminator character.

/Z[=z] Prevents aborting of procedure execution when attempting to copy to a nonexistent file. Use */Z* if you want to handle this case in your procedures rather than having execution abort.

z=0: Same as no */Z* at all.

z=1: Copy file only if it exists. */z* alone is the same as */z=1*.

z=2: Copy file if it exists and display a dialog if it does not exist.

Line Termination

Line termination applies mostly to source and destination files. (The Clipboard and history area delimit lines with CR, and text waves have no line terminators.)

If */T* is omitted, Grep will break file lines on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.)

Grep reads whichever of these terminator(s) appear in the source file and use them to write lines to any output file.

The terminator(s) are removed before the line is matched against the regular expression.

For lines that match *regExprStr*, terminator(s) in the input file are transferred to the output file unless the output is the Clipboard or history area, in which case the output terminator is always only CR (like **LoadWave**). This means you can transparently handle files that use CR, LF, CRLF, or LFCR as the terminator, and omitting */T* will be suitable for most cases.

If you use the */T* flag, then Grep will terminate line-from-file reads on the specified character only and will output the specified character into any output file.

"Lines" in One-dimensional Text Waves

Grep considers each row of *srcTextWaveName* or *destTextWaveName* to be a "line" of input or output.

When the destination is a file, the Clipboard, or the History area, Grep copies all of the text in a matching row of *srcTextWaveName* to the file and terminates the line. See **Line Termination** for the rules on line terminators.

When the destination is a *destTextWaveName*, Grep simply copies all the text in a matching row to a row in *destTextWaveName*, without adding or omitting any terminators.

"Lines" and Columns in Two-Dimensional Text Waves

Grep by default *matches* against only the first column (column 0) of each row of *srcTextWaveName*. You can use the */GCOL=grepCol* flag to specify a different column to match against. Use */GCOL=-1* to match against any column of *srcTextWaveName*.

When the source is a text wave and the destination is a file, the Clipboard, or the History area, Grep by default *copies* only the first column (column 0) to the destination.

Use the */DCOL={colNum1, delimStr1, colNum2, delimStr2, ... colNumN}* to print multiple columns (in any order) with delimiters after each column (the last column number need not be followed by a delimiter string). The output line is terminated with CR or *termcharStr* as described in **Line Termination**.

When both the source and destination are text waves and append (*/A*) is *not* specified, the destination text wave is redimensioned to have the same number of columns as the source text wave, and all columns of matching rows of *srcTextWaveName* are copied to *destTextWaveName*.

When both the source and destination are text waves and append /A is specified, then the number of columns in *destTextWaveName* is left unchanged, and each column of *srcTextWaveName* is copied to the corresponding column of *destTextWaveName*.

If the destination is a text wave and the source is a file or the Clipboard, each line (without the terminator) is copied to the first column of the destination text wave, or use /DCOL={*destColNum*} to put the text into a different column.

Variables

The Grep operation returns information in the following variables:

V_flag	0: Output successfully generated. -1: User cancelled either the Open File or Save File dialogs. >1: An error occurred, such as the specified file does not exist.
V_value	The number of input lines that matched the regular expression.
V_startParagraph	Zero-based line number into the file or Clipboard (or the row number of a source text wave) where the first regular expression was matched. Also see the /INDX flag.
S_fileName	Full path to the source file, the source text wave, or "Clipboard". If an error occurred or if the user cancelled, it is an empty string.
S_path	Full path to the destination file or destination text wave. "Clipboard": If <i>destFileOrFolderStr</i> was the Clipboard. "History": If the output was printed to the History window. "": If an error occurred, if the user cancelled, or if /Q was specified.
S_value	Contains matching lines as a string list only if /LIST is specified.

Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the "subject".

In the case of Grep, the "subject" is each line of the source file or Clipboard, or each row in the source text wave.

The regular expression syntax supported by Grep, **GrepList**, and **GrepString** is based on the "Perl-Compatible Regular Expression" (PCRE) library.

The syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. See **Regular Expressions** on page IV-126 for more details. Igor's implementation does not support the Unicode (UTF-8) portion of PCRE.

As a trivial example, the pattern "Fred" as specified here:

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
```

matches lines that contain the string "Fred" anywhere on the line.

Character matching is *case-sensitive* by default, similar to `strsearch`. Prepend the Perl 5 modifier `(?i)` to match upper and lower-case versions of "Fred":

```
// Copy lines that contain "Fred", "fred", "FRED", "fRED", etc  
Grep/P=myPath/E="(?)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do *not* match the regular expression, set the /E flag's reverse parameter:

```
// Copy lines that do NOT contain "Fred", "fred", "fRED", etc.  
Grep/P=myPath/E="{(?)fred",1} "afile.txt" as "NotFredFile.txt"
```

Note: Igor doesn't use the opening and closing regular expression delimiters that UNIX `grep` or Perl use: they would have used `"/Fred/"` and `"/(?)fred/"`.

Regular expressions in Igor support the expected metacharacters and character classes that make the whole `grep` paradigm so useful. For example:

```
// Copy lines that START with a space or tab character  
Grep/P=myPath/E="^[ \t]" "afile.txt" as "LeadingTabsFile.txt"
```

For a complete description of regular expressions, see **Regular Expressions** on page IV-126, especially for a description of the many uses of the regular expression backslash character (see **Backslash in Regular Expressions** on page IV-127).

Note: Because Igor Pro also has special uses for backslash (see **Escape Characters in Strings** on page IV-13), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes identifies a single backslash for the Grep command.

For example, to copy lines that contain "\z", the Perl pattern would be \\z, but the equivalent Grep expression would be /E="\\\\z".

See **Backslash in Regular Expressions** on page IV-127 for a more complete description of backslash behavior in Igor Pro.

Examples

```
// Copy lines in afile.txt containing "Fred" (case sensitive)
// to an output file named "AnyFredFile.txt" in the same directory.
Grep/P=myPath/E="Fred" "afile.txt" as "AnyFredFile.txt"

// Copy lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to a text wave (which must exist and is overwritten):
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="( ?i)fred"/E="( ?i)wilma" "afile.txt" as outputTextWave

// Print lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to the history area
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="( ?i)fred"/E="( ?i)wilma" "afile.txt"

// Test whether afile.txt contains the word "boondoggle", and if so,
// on which line the first occurrence was found, WITHOUT creating any output.
//
// Note: the \\b sequences limit matches to a word boundary before and after
// "boondoggle", so "boondoggles" and "aboondoggle" won't match.
//
Grep/P=myPath/Q/E="( ?i)\\bBoondoggle\\b" "afile.txt"
if( V_value ) // at least one instance was found
    Print "First instance of \"boondoggle\" was found on line", V_startParagraph
endif

// Create in S_value a string list of the lines as \r - separated list items:
Grep/P=myPath/LIST="\r"/Q/E="( ?i)\\bBoondoggle\\b" "afile.txt"
if( V_value ) // some were found
    Print S_value
endif

// Create in W_index a list of the 0-based line numbers where "boondoggle"
// or "boondoggles", etc was found in afile.txt.
Grep/P=myPath/INDX/Q/E="( ?i)boondoggle" "afile.txt"
if( V_flag ) // grep succeeded, perhaps none were found; let's see where
    WAVE W_index // needed if in a function
    Edit W_index // show line numbers in a table.
endif

// (Create a string list and text wave for the following examples.)
String list= CTabList() // "Grays;Rainbow;YellowHot;..."
Variable items= ItemsInList(list)
Make/O/T/N=(items) textWave= StringFromList(p,list)

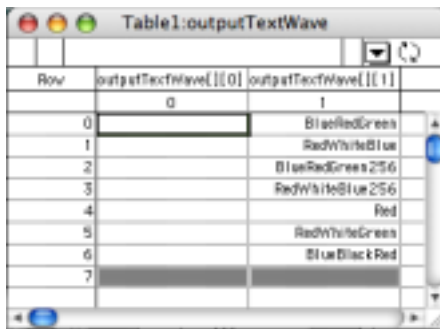

// Copy rows of textWave that contain "Red" (case sensitive)
// to the Clipboard as carriage-return separated lines.
Grep/E="Red" textWave as "Clipboard"

// Copy lines of the Clipboard that do NOT contain "Blue"
// (case in-sensitive) back to the Clipboard, overwriting what was there:
Grep/E="{( ?i)blue",1} "Clipboard" as "Clipboard"

// Format matching text wave row to the history area
Grep/E=("Red")/DCOL={"prefix text --- ", 0, " --- suffix text"} textWave

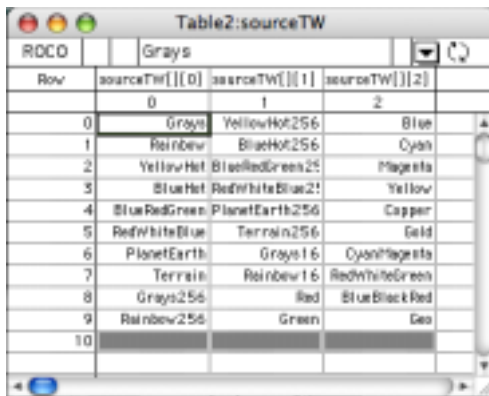

// Printed output:
prefix text --- BlueRedGreen --- suffix text
prefix text --- RedWhiteBlue --- suffix text
prefix text --- BlueRedGreen256 --- suffix text
prefix text --- RedWhiteBlue256 --- suffix text
prefix text --- Red --- suffix text
prefix text --- RedWhiteGreen --- suffix text
prefix text --- BlueBlackRed --- suffix text

// Create a 2-column text wave whose column 1 (the second column)
// contains the matching text from the Clipboard
Make/O/N=(0,2)/T outputTextWave
// Grep with /A to preserve 2 columns of outputTextWave
Grep/A/E="Red"/GCOL=1/DCOL={1} "Clipboard" as outputTextWave
```

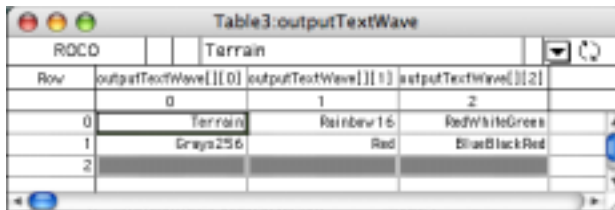

Row	outputTextWave[[0]]	outputTextWave[[1]]
	0	1
0		BlackRedGreen
1		RedWhiteBlue
2		BlueRedGreen256
3		RedWhiteBlue256
4		Red
5		RedWhiteGreen
6		BlueBlackRed
7		

```
// Examples with two-dimensional source text waves
Make/O/T/N=(10, 3) sourceTW= StringFromList(p+10*q,list)
Edit sourceTW
```

Row	sourceTW[[0]]	sourceTW[[1]]	sourceTW[[2]]
	0	1	2
0	Grays	YellowHot256	Blue
1	Rainbow	BlueHot256	Cyan
2	YellowHot	BlackRedGreen25	Magenta
3	BlueHot	RedWhiteBlue256	Yellow
4	BlueRedGreen	PlanetEarth256	Copper
5	RedWhiteBlue	Terrain256	Gold
6	PlanetEarth	Grays16	CyanMagenta
7	Terrain	Rainbow16	RedWhiteGreen
8	Grays256	Red	BlueBlackRed
9	Rainbow256	Green	Geo
10			

```
// Copy rows of textWave that contain "Red" in column 2 to outputTextWave.
Make/O/N=0/T outputTextWave
Grep/E="Red"/GCOL=2 sourceTW as outputTextWave
Edit outputTextWave
```

Row	outputTextWave[[0]]	outputTextWave[[1]]	outputTextWave[[2]]
	0	1	2
0	Terrain	Rainbow16	RedWhiteGreen
1	Grays256	Red	BlueBlackRed
2			

```
// Format matching text wave columns to the history area.
// Match lines that contain "Red" in any column of sourceTW:
Grep/E=("Red")/GCOL=-1/DCOL={0,"", "1"," ", "2} sourceTW
// Printed output:
YellowHot, BlueRedGreen256, Magenta
BlueHot, RedWhiteBlue256, Yellow
BlueRedGreen, PlanetEarth256, Copper
RedWhiteBlue, Terrain256, Gold
Terrain, Rainbow16, RedWhiteGreen
Grays256, Red, BlueBlackRed
```

References

The regular expression syntax supported by Grep, **GrepString**, and **GrepList** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <http://pcre.org/> for more information about the PCRE library, and <http://www.perldoc.com/> for more about Perl regular expressions. The description of regular expressions above is taken from the PCRE documentation.

A good book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

See Also

Regular Expressions on page IV-126 and **Symbolic Paths** on page II-30.

SplitString, **CopyFile**, **PutScrapText**, **LoadWave** operations. The **GrepString**, **GrepList**, **stringmatch**, and **cmpstr** functions.

GrepList

GrepList(listStr, regExprStr [,reverse [, listSepStr]])

The GrepList function returns each list item in *listStr* that matches the regular expression *regExprStr*.

ListStr should contain items separated by the *listSepStr* character, such as in "abc;def;".

regExprStr is a regular expressions such as is used by the UNIX **grep**(1) command. It is much more powerful than the wildcard syntax used for **ListMatch**. See **Regular Expressions** on page IV-126 for *regExprStr* details.

reverse is optional. If missing, it is taken to be 0. If *reverse* is nonzero then the sense of the match is reversed. For example, if *regExprStr* is "^abc" and *reverse* is 1, then all list items that do not start with "abc" are returned.

listSepStr is optional; the default is ";". In order to specify *listSepStr*, you must precede it with *reverse*.

Examples

To list ColorTables containing "Red", "red", or "RED" (etc.):

```
Print GrepList(CTabList(), "(?i)red")           // case-insensitive matching
```

To list window recreation commands starting with "\tCursor":

```
Print GrepList(WinRecreation("Graph0", 0), "^\\tCursor", 0, "\\r")
```

See Also

Regular Expressions on page IV-126.

ListMatch, **StringFromList**, and **WhichListItem** functions and the **Grep** operation.

GrepString

GrepString(string, regExprStr)

The GrepString function tests *string* for a match to the regular expression *regExprStr*. Returns 1 to indicate a match, or 0 for no match.

Details

regExprStr is a regular expressions such as is used by the UNIX **grep**(1) command. It is much more powerful than the wildcard syntax used for **stringmatch**. See **Regular Expressions** on page IV-126 for *regExprStr* details.

Character matching is case-sensitive by default, similar to **strsearch**. Prepend the Perl 5 modifier "(?i)" to match upper and lower-case text

Examples

Test for truth that the string contains at least one digit:

```
if( GrepString(str, "[0-9]+") )
```

Test for truth that the string contains at least one "abc", "Abc", "ABC", etc.:

```
if( GrepString(str, "(?i)abc") )           // case-insensitive test
```

Regular Expressions on page IV-126.

The **stringmatch**, **cmpstr**, **strsearch**, **ListMatch**, and **ReplaceString** functions and the **SplitString** and **sscanf** operations.

GroupBox

GroupBox [/Z] ctrlName [key [= value]][, key [= value]]...

The GroupBox operation creates a box to surround and group related controls.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the GroupBox control to be created or changed.

key is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of `default`, `native`, or `os9`.

platform can be one of `Mac`, `Win`, or `All`.

See **DefaultGuiControls Default Fonts and Sizes** for how enclosed controls are affected by native groupbox appearance.

See **Button** for more appearance details.

disable=*d*

Sets user editability of the control.

d=0: Normal.

d=1: Hide.

d=2: Draw in gray state.

fColor=(*r,g,b*)

Sets color of the title text. *r*, *g*, and *b* are integers from 0 to 65535.

font="*fontName*"

Sets font used for the box title, e.g., font="Helvetica".

frame=*f*

Sets frame mode. If 1 (default), the frame has a 3D look. If 0, then a simple gray line is used. Generally, you should not use frame=0 with a title if you want to be in accordance with human interface guidelines.

fsize=*s*

Sets font size for box title.

fstyle=*fs*

Sets the font style of the title text. *fs* is a binary coded number with each bit controlling one aspect of the font style for the tick mark labels as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

labelBack=(*r,g,b*) or 0

Sets fill color for the interior. *r*, *g*, and *b* are integers from 0 to 65535. If not set, then interior is transparent. Note that if a fill color is used, draw objects can not be used because they will be covered up. Also, you will have to make sure the GroupBox is drawn before any interior controls.

pos={*left,top*}

Sets absolute location of box in pixels.

size={*width,height*}

Sets box size in pixels.

userdata(*UDName*)=*UDStr*

Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

userdata(*UDName*)+=*UDStr*

Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

title=*titleStr*

Sets title to *titleStr*. Use "" for no title.

win=*winName*

Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

If no title is given and the width is less than 11 or height is specified as less than 6, then a vertical or horizontal separator line will be drawn rather than a box.

Note: Like TabControls, you need to click near the top of a GroupBox to select it.

See Also

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

GuideInfo

GuideInfo(*winNameStr*, *guideNameStr*)

The GuideInfo function returns a string containing a semicolon-separated list of information about the named subwindow guide line in the named host window or subwindow.

Parameters

winNameStr can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

guideNameStr is the name of the guide line for which you want information.

Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
NAME	Name of the guide.
WIN	Name of the window or subwindow containing the guide.
TYPE	The value associated with this keyword is either <i>User</i> or <i>Builtin</i> . A <i>User</i> type denotes a guide created by the DefineGuide operation, equivalent to dragging a new guide from an existing one.
HORIZONTAL	Either 0 for a vertical guide, or 1 for a horizontal guide.
POSITION	The position of the guide. This is the actual position relative to the left or bottom edge of the window, not the relative position specified to DefineGuide.

The following keywords will be present only for user-defined guides:

Keyword	Information Following Keyword
GUIDE1	The guide is positioned relative to GUIDE1.
GUIDE2	In some cases, the guide is positioned at a fractional position between GUIDE1 and GUIDE2. If the guide does not use GUIDE2, the value will be "".
RELPOSITION	The position relative to GUIDE1 (and GUIDE2 if applicable). This is the same as the <i>val</i> parameter in DefineGuide. May be a number of pixels if only GUIDE1 is used, or a fractional value if both GUIDE1 and GUIDE2 are used.

See Also

The **StringByKey** and **NumberByKey** functions; the **DefineGuide** operation.

Hanning

Hanning *waveName* [, *waveName*]...

Note: The **WindowFunction** operation has replaced the Hanning operation.

The Hanning operation multiplies the named waves by a Hanning window (which is a raised cosine function).

You can use Hanning in preparation for performing an FFT on a wave if the wave is not an integral number of cycles long.

The Hanning operation is not multidimensional aware. See Chapter II-6, **Multidimensional Waves**, particularly **Analysis on Multidimensional Waves** on page II-94 for details.

Hash

See Also

The **WindowFunction** operation implements the Hanning window as well as other forms such as Hamming, Parzen, and Bartlet (triangle).

The **ImageWindow** operation for windowing of images.

Hash

Hash(inputStr, method)

The Hash function returns a message digest string for *inputStr*. The length of the resulting hash string is fixed for each algorithm.

Parameters

inputStr is a string of arbitrary length.

method is 1 to use Secure Hash Algorithm-256.

See Also

For more about the SHA-256 algorithm see: <<http://en.wikipedia.org/wiki/SHA-1>>.

hcsr

hcsr(cursorName [, graphNameStr])

The hcsr function returns the horizontal coordinate of the named cursor (A through J) in the coordinate system of the top (or named) graph's X axis.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The X axis used is the one that controls the trace on which the cursor is placed.

Examples

```
Variable xAxisValueAtCursorA = hcsr(A)           // not hcsr("A")
String str="A"
Variable xA= hcsr($str,"Graph0")                 // $str is a name, too
```

See Also

The **Cursor** operation and the **CsrInfo**, **pcsr**, **qcsr**, **vcsr**, **xcsr**, and **zcsr** functions.

hermite

hermite(n, x)

The hermite function returns the Hermite polynomial of order *n*:

$$H_n(x) = (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

The first few polynomials are:

$$\begin{aligned} &1 \\ &2x \\ &4x^2 - 2 \\ &8x^3 - 12x \end{aligned}$$

See Also

The **hermiteGauss** function.

hermiteGauss

hermiteGauss(*n*, *x*)

The hermiteGauss function returns the normalized Hermite polynomial of order *n*:

$$H_n(x) = \frac{1}{\sqrt{\sqrt{\pi} 2^n n!}} (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

Here the normalization was chosen such that $\int_{-\infty}^{\infty} H_n(x) H_m(x) dx = \delta_{nm}$ where δ_{nm} is the Kronecker symbol.

See Also

The **hermite** function.

HideIgorMenus

HideIgorMenus [*MenuNameStr* [, *MenuNameStr*]...

The HideIgorMenus operation hides the named built-in menus or, if none are explicitly named, hides all built-in menus in the menu bar.

The effect of HideIgorMenus is lost when a new experiment is opened. The state of HideIgorMenus is saved with the experiment.

User-defined menus are not hidden by HideIgorMenus unless attached to built-in menus and the menu definition uses the hideable keyword.

Parameters

MenuNameStr The name of an Igor menu, like "File", "Data", or "Graph".

Details

The optional menu names are in English and not abbreviated. This ensures that code developed for a localized version of Igor will run on all versions.

The built-in menus that can be shown or hidden (the Help menu can be hidden only on Windows) are those that appear in the menu bar:

File	Edit	Data	Analysis	Macros	Windows	Graph
Layout	Notebook	Panel	Procedure	Table	Misc	Help

Hiding a built-in menu to which a user-defined menu is attached results in a built-in menu with only the user-defined items. For example, if this menu definition attaches items to the built-in Graph menu:

```
Menu "Graph"
  "Do My Graph Thing", ThingFunction()
End
```

Calling HideIgorMenus "Graph" will still leave a Graph menu showing (when a Graph is the top-most target window) with only the user-defined menu(s) in it: in this example the one "Do My Graph Thing" item.

Hiding the Macros menu hides menus created from Macro definitions like:

```
Macro MyMacro()
  Print "Hello, world."
End
```

but does not hide normal user-defined "Macros" definitions like:

```
Menu "Macros"
  "Macro 1", MyMacro(1)
End
```

You can set user-defined menus to hide and show along with built-in menus by adding the optional hideable keyword to the menu definition:

```
Menu "Graph", hideable
  "Do My Graph Thing", ThingFunction()
End
```

Then HideIgorMenus "Graph" will hide those items, too. If all user-defined Graph menu definitions use the hideable keyword, then no Graph menu will appear in the menu bar.

HideInfo

Some WaveMetrics procedures use the `hideable` keyword so that only customer-defined menus remain when `HideIgorMenus` is executed.

See Also

Chapter IV-5, **User-Defined Menus**.

The **ShowIgorMenus**, **DoIgorMenu**, and **SetIgorMenuMode** operations.

HideInfo

HideInfo [/W=*winName*]

The `HideInfo` operation removes the info box from a graph if it was previously shown by the **ShowInfo** operation.

Flags

/W=*winName* Hides the info box in the named window.

See Also

The **ShowInfo** operation.

HideProcedures

HideProcedures

The `HideProcedures` operation hides all procedure windows without closing or killing them.

See Also

The **DisplayProcedure** and **DoWindow** operations.

HideTools

HideTools [/A/W=*winName*]

The `HideTools` operation hides the tool bar in the top graph or control panel if it was previously shown by the **ShowTools** operation.

Flags

/A Sizes the window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=*winName* Hides the tool bar in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

See Also

The **ShowTools** operation.

HilbertTransform

HilbertTransform [/Z] [/O] [/DEST=*destWave*] *srcWave*

The `HilbertTransform` operation computes the Hilbert transformation of *srcWave*, which is a real or complex (single or double precision) wave of 1-3 dimensions. The result of the `HilbertTransform` is stored in *destWave*, or in the wave `W_Hilbert` (1D) or `M_Hilbert` in the current data folder.

Flags

/DEST=*destWave* Creates a real wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-53 for details.

/O Overwrites *srcWave* with the transform.

/Z No error reporting.

Details

The Hilbert transform of a function $f(x)$ is defined by:

$$F(t) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{f(x)}{t-x} dx .$$

Theoretically, the integral is evaluated as a Cauchy principal value. Computationally one can write the Hilbert transform as the convolution:

$$F(t) = \frac{1}{\pi t} \cdot f(t),$$

which by the convolution theorem of Fourier transforms, may be evaluated as the product of the transform of $f(x)$ with $-i \cdot \text{sgn}(x)$ where:

$$\text{sgn}(x) = \begin{cases} -1 & x < 0 \\ 0 & x = 0 \\ 1 & x > 0 \end{cases}.$$

Note that the Hilbert transform of a constant is zero. If you compute the Hilbert transform in more than one dimension and one of the dimensions does not vary (is a constant), the transform will be zero (or at least numerically close to zero).

Examples

Extract the instantaneous amplitude and frequency of a narrow-band signal.

```
Make /o/n=1000 w0,amp,phase
SetScale/I x 0,50,"", w0,amp,phase
w0 = exp(-x/10)*cos(2*pi*x)
HilbertTransform /DEST=w0h w0 // w0+i*w0h is the "analytic signal", i=cplx(0,1)
amp = sqrt(w0^2 + w0h^2) // extract the envelope
phase = atan2(-w0h,w0) // extract the phase [SIGN CONVENTION?]
Unwrap 2*pi, phase // eliminate the 2*pi phase jumps
Differentiate phase /D=freq // would have less noise if fit to a line
// over interior points
freq /= 2*pi // phase = 2*pi*freq*time
Display w0,amp // original waveform and its envelope; note boundary effects
Display freq // instantaneous frequency estimate, with boundary effects
```

Histogram

Histogram [*flags*] *srcWaveName*, *destWaveName*

The Histogram operation generates a histogram of the data in *srcWaveName* and puts the result in *destWaveName*.

Flags

/A Accumulates the histogram result with the existing values in *destWaveName* instead of replacing the existing values with the result. Assumes /B=2 unless the /B flag is present.

Note: The result will be incorrect if you also use /P.

/B=mode *mode*=1: Semiauto mode that sets the bin range based on the range of the Y values in *srcWaveName*. The number of bins is determined by the number of points in *destWaveName*.

mode=2: Uses the bin range and number of bins determined by the X scaling and number of points in *destWaveName*.

mode=3: Uses Sturges' method to determine optimal number of bins and to redimension *destWaveName* as necessary. By this method $\text{numBins} = 1 + \log_2(N)$, where N is the number of data points in *srcWaveName*. The bins will be distributed so that they include the minimum and maximum values.

mode=4: Uses a method due to Scott, which determines the optimal bin width as $\text{binWidth} = 3.49 * s * N^{-1/3}$, where N is the number of data points in *srcWaveName* and s is the standard deviation of the distribution. The bins will be distributed so that they include the minimum and maximum values.

/B={*binStart*,*binWidth*,*numBins*}

Sets the histogram bins from these parameters rather than from *destWaveName*.
Changes the X scaling and length of *destWaveName*.

Histogram

/C	Sets the X scaling so that X values are in the centers of the bins, which is required when you do a curve fit to the histogram output. Ordinarily, wave scaling of the output wave is set with X values at the left bin edges.
/CUM	Requests a cumulative histogram in which each bin is the sum of bins to the left. The last bin will contain the total number of input data points, or, with /P, 1.0. When used with /A, the destination wave must be the result of a histogram created with /CUM.
/N	Creates a wave (W_SqrtN) containing the square root of the number of counts in each bin. This is an appropriate wave to use as a weighting wave when doing a curve fit to the histogram results.
/P	Normalizes the histogram as a probability distribution function, and shifts wave scaling so that data correspond to the bin centers. When using the results with Integrate , you must use /METH=0 or 1 because the trapezoidal approximation will give an error whose magnitude depends on the distribution function starting value.
/R=(startX,endX)	Specifies the range of X values of <i>srcWaveName</i> over which the histogram is to be computed.
/R=[startP,endP]	Specifies the range of points of <i>srcWaveName</i> over which the histogram is to be computed.
/W=weightWave	Creates a “weighted” histogram. In this case, instead of adding a single count to the appropriate bin, the corresponding value from <i>weightWave</i> is added to the bin. <i>weightWave</i> may be any number type, and it may be complex. If it is complex, then the destination wave will be complex.

Details

You must create a destination wave before doing the histogram. If you use /B={*binStart*, *binWidth*, *numBins*}, then the initial number of data points in the wave is unimportant since the Histogram operation changes the number of points.

Only one /B and only one /R flag is allowed.

If both /A and /B flags are missing, the bin range and number of bins is calculated as if /B=1 (auto-set) had been specified.

Typically, you will want to use /B={*binStart*, *binWidth*, *numBins*} for the first histogram, and /A for successive accumulations into the histogram.

The Histogram operation works on single precision floating point destination waves. If necessary, Histogram redimensions *destWaveName* to be single precision floating point. However, Histogram/A requires that *destWaveName* already be single precision floating point.

For a weighted histogram, the destination wave will be double-precision.

If you specify the range as /R=(*start*), then the end of the range is taken as the end of *srcWaveName*.

In an ordinary histogram, input data is examined one data point at a time. The operation determines which bin a data value falls into and a single count is added to that bin. A weighted histogram works similarly, except that it adds to the bin a value from another wave in which each row corresponds to the same row in the input wave.

The Histogram operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details. In fact, the Histogram operation can be usefully applied to multidimensional waves, such as those that represent images. The /R flag will not work as expected, however.

Examples

```
// Create histogram of two sets of data.
Make/N=1000 data1=gnoise(1), data2=gnoise(1)
Make/N=1 histResult

// Sets bins, does histogram.
Histogram/B={-5,1,10} data1, histResult
Display histResult; ModifyGraph mode=5

// Accumulates into existing bins.
Histogram/A data2, histResult
```

The **hyperG0F1**, **hyperG1F1**, and **hyperGPFQ** functions.

References

The PFQ algorithm was developed by Warren F. Perger, Atul Bhalla, and Mark Nardin.

hyperGNoise

hyperGNoise(*m*, *n*, *k*)

The hyperGNoise function returns a pseudo-random value from the hypergeometric distribution whose probability distribution function is

$$f(x, m, n, k) = \frac{\binom{n}{x} \binom{m-n}{k-x}}{\binom{m}{k}}$$

where *m* is the total number of items, *n* is the number of marked items, and *k* is the number of items in a sample.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

i

i

The i function returns the loop index of the inner most iterate loop in a macro. Not to be used in a function. iterate loops are archaic and should not be used.

if-elseif-endif

```

if ( <expression1> )
    <TRUE part 1>
elseif ( <expression2> )
    <TRUE part 2>
[... ]
[else
    <FALSE part>]
endif

```

In an if-elseif-endif conditional statement, when an expression first evaluates as TRUE (nonzero), then only code corresponding to the TRUE part of that expression is executed, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is executed when present. After executing code in any TRUE part or the FALSE part, execution will next continue with any code following the if-elseif-endif statement.

See Also

If-Elseif-Endif on page IV-31 for more usage details.

if-endif

```

if ( <expression> )
    <TRUE part>
[else
    <FALSE part>]
endif

```

An if-endif conditional statement evaluates *expression*. If *expression* is TRUE (nonzero) then the code in *TRUE part* is executed, or if FALSE (zero) then the optional *FALSE part* is executed.

See Also

If-Else-Endif on page IV-30 for more usage details.

IFFT

IFFT [*flags*] *waveName*

The IFFT operation calculates the Inverse Discrete Fourier Transform of *waveName* using a multidimensional fast prime factor decomposition algorithm. This operation is the inverse of the FFT operation.

Unless the /DEST flag is used, it replaces *waveName* with the IFFT.

Parameters

waveName is the name of a complex wave. The IFFT of *waveName* is either a real or complex wave, according to the length and flags.

Flags

- /C Forces the result of the IFFT to be complex. Normally, the IFFT produces a real result unless certain special conditions are detected as described in **Details**.
- /COLS Computes the 1D IFFT of 2D *srcWave* one column at a time, storing the results in the destination wave. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /ROWS flag and corresponding flags of the FFT operation.
- /DEST=*dataFolderAndName* Saves the IFFT result in a wave specified by *dataFolderAndName*. The destination wave will be created or overwritten if it already exists. *dataFolderAndName* can include a full or partial path with the wave name (/DEST=root:bar:destWave).
In a function, IFFT by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-53 for details.
- /R Forces real output when, due to a power of 2 number of points, IFFT would otherwise automatically produce a complex result.
- /ROWS Calculates the IFFT of only the first dimension of 2D *srcWave*. It computes the 1D FFT one row at a time. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /COLS flag and corresponding flags of the FFT operation.

/Z Will not rotate *waveName* when computing the IDFT of a complex wave whose length is an integral power of 2.

This length indicates that the Inverse DFT result will also be a complex wave. When the result is complex, *and* the x scaling of *waveName* is such that the first point is *not* x=0, it normally rotates *waveName* by -N/2 points before performing the IFFT. This inverts the process of performing an FFT on a complex wave. However when */Z* is specified, it does not perform this rotation.

Details

The data type of *waveName* must be complex and must not be an integer type. You should be aware that an IFFT on a number of points that is prime can be slow.

By default, IFFT assumes you are performing an inverse transform on data that was originally real and therefore it produces a real result. However, for historical and compatibility reasons, IFFT detects the special conditions of a one-dimensional wave containing an integral power of 2 data points and automatically creates a complex result.

When the result is complex, the number of points (N) in the resulting wave will be of the same length. Otherwise the resulting wave will be real and of length (N-1)*2.

In either the complex or real case the X units of the output wave are changed to "s". The X scaling also is changed appropriately, cancelling out the adjustments made by the FFT operation. When the data is multidimensional, the same considerations apply to the additional dimensions. The scaling description and IDFT equation below pretend that the IFFT is not performed in-place. After computing the IFFT values, the X scaling of *waveOut* is changed as if Igor had executed these commands:

```
Variable points // time-domain points, NtimeDomain
if( waveIn was complex wave )
    points= numpnts(waveIn)
else // waveIn was real wave
    points= (numpnts(waveIn) - 1) * 2
endif
Variable deltaT= 1 / (points*deltaX(waveIn)) // 1/(NtimeDomainΔx)
SetScale/P waveOut 0,deltaT,"s"
```

The IDFT equation is:

$$waveOut[n] = \frac{1}{N} \cdot \sum_{k=0}^{N-1} waveIn[k] \cdot e^{-2\pi \cdot i \cdot k \cdot n / N}, \text{ where } i = \sqrt{-1}.$$

See Also

The **FFT**, **DSPPeriodogram**, and **MatrixOP** operations.

IgorInfo

IgorInfo(*selector*)

The IgorInfo function returns information about the Igor application and the environment in which it is running.

Details

If *selector* is 0, IgorInfo returns a collection of assorted information. The result string contains five kinds of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are IGORVERS, IGORKIND, FREEMEM, NSCREENS, and SCREEN*n* where *n* varies from 1 to the number of screens (monitors) currently attached to the computer and used for the desktop.

Keyword	Information Following Keyword
FREEMEM	The amount of free memory available to Igor. When running under virtual memory, such as on Windows, this is the amount of free virtual memory.
IGORKIND	The type of Igor application; "pro" means the full (nondemo) version of Igor Pro. "pro demo" is the demo version of Igor Pro. Currently there are no other values for this keyword.
IGORVERS	The version number of the Igor application. Also see IGORFILEVERSION returned by IgorInfo(3).
NSCREENS	Number of screens (monitors) currently attached to the computer and used for the desktop. In Igor Pro 4 this was erroneously " NSCREENS" (with a leading space).

Keyword	Information Following Keyword
SCREEN1	<p>Description of the characteristics of screen 1.</p> <p>On Macintosh, the screen number corresponds to the number in the Monitors Control Panel; use the Identify button there to show the monitor (screen) numbers. SCREEN1 is not necessarily the monitor with the menu bar.</p> <p>On Windows, SCREEN1 is the main monitor (whose top left corner screen coordinate is 0, 0).</p> <p>Format of the SCREEN description is:</p> <p>SCREENn:DEPTH=<i>bitsPerPixel</i>,RECT=<i>left,top,right,bottom</i>; <i>left, top, right</i>, and <i>bottom</i> are all in pixels.</p>
SCREEN n	Description of the characteristics of the last screen. See NSCREENS, above.

If *selector* is 1, IgorInfo returns the name of the current Igor experiment.

If *selector* is 2, IgorInfo returns the name of the current platform: "Macintosh" or "Windows".

If *selector* is 3, IgorInfo returns a collection of more detailed information about the operating system, localization information, and the actual file version of the Igor executable. The keywords are OS, OSVERSION, LOCALE, and IGORFILEVERSION.

If *selector* is 4, IgorInfo returns the name of the current processor architecture: "PowerPC" or "Intel".

Keyword	Information Following Keyword
IGORFILEVERSION	<p>The actual version number of the Igor application file.</p> <p>On the Macintosh, the version number is a floating point number with a possible suffix. Igor Pro 5.00, for example, returns "5.00". Igor Pro 5.02A returns "5.02A".</p> <p>As of Igor Pro 5.02, the Windows version format is a period-separated list of four numbers. Igor Pro 5.02 returns "5.0.2.0". A revision to Igor Pro 5.02 would be indicated in the last digit, such as "5.0.2.12".</p> <p>(For versions older than 5.02, the Windows version format is a floating point number similar to the Macintosh. For example, Igor 4.09A returns "4.091". We abandoned this representation because it limits each of the digits to 0-9.)</p>
LOCALE	Country for which this version of Igor Pro is localized. "US" for most versions, "Japan" for the Japanese versions.
OS	<p>Description of operating system.</p> <p>On Macintosh, OS value is "Macintosh Classic", "Macintosh Carbon", or "Macintosh OS X".</p> <p>On Windows, this might be "Windows 95 OSR2", "Windows 98 SE", "Windows Me", "Windows NT Personal (Build 1234)", "Windows 2000 (Build 1234)", "Windows XP (Build 1234)". Of course, the actual build number and format of the text will vary with the operating system.</p>
OSVERSION	<p>Operating system number.</p> <p>On Macintosh, this might be "9.1.0", "10.1.2" etc.</p> <p>On Windows, this might be "4,0,0,1998".</p>

Always pass 0, 1, 2, 3, or 4 as the input parameter. In future versions of Igor Pro, this parameter may request other kinds of information.

Examples

```
Print NumberByKey("IGORVERS", IgorInfo(0))
```

IgorVersion

#pragma IgorVersion = versNum

When a procedure file contains the directive, `#pragma IgorVersion=versNum`, an error will be generated if *versNum* is greater than the current Igor Pro version number. It prevents procedures that use new features added in later versions from running under older versions of Igor in which these features are missing. However, this version check is limited because it does not work with versions of Igor older than 4.0.

See Also

The **The IgorVersion Pragma** on page IV-40 and **#pragma**.

ilim

ilim

The `ilim` function returns the ending loop count for the inner most iterate loop. Not to be used in a function. Iterate loops are archaic and should not be used.

imag

imag(z)

The `imag` function returns the imaginary component of the complex number *z* as a real (not complex) number.

See Also

The **cmplx**, **conj**, **p2rect**, **r2polar**, and **real** functions.

ImageAnalyzeParticles

ImageAnalyzeParticles [flags] keyword imageMatrix

The `ImageAnalyzeParticles` operation performs one of two particle analysis operations on a 2D or 3D source wave *imageMatrix*. The source image wave must be binary, i.e., an unsigned char format where the particles are designated by 0 and the background by 255 (the operation will produce erroneous results if your data uses the opposite designation). Note that all nonzero values in the source image will be considered part of the background. Grayscale images must be thresholded before invoking this operation (you may need to use the `/I` flag with the **ImageThreshold** operation).

Note: `ImageAnalyzeParticles` does not take into account wave scaling. All image metrics are in pixels and all pixels are assumed to be square.

Parameters

keyword is one of the following names:

mark	Creates a masking image for a single particle, which is specified by an internal (seed) pixel using the <code>/L</code> flag. The masking image is stored in the wave <code>M_ParticleMarker</code> , which is an unsigned char wave. All points in <code>M_ParticleMarker</code> are set to 64 (image operations on binary waves use the value 64 to designate the equivalent of NaN) except points in the particle which are set to the 0. This wave is designed to be used as an overlay on the original image (using the <code>explicit=1</code> mode of <code>ModifyImage</code>). This keyword is superseded by the ImageSeedFill operation.												
stats	Measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the <i>minArea</i> specified by the <code>/A</code> flag. The results of the measurements are: <table> <tr> <td>V_NumParticles</td><td>Number of particles that exceed the <i>minArea</i> limit.</td></tr> <tr> <td>W_ImageObjArea</td><td>Area (in pixels) for each particle.</td></tr> <tr> <td>W_ImageObjPerimeter</td><td>Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.</td></tr> <tr> <td>W_circularity</td><td>Ratio of the square of the perimeter to ($4*\pi*\text{objectArea}$). This value approaches 1 for a perfect circle.</td></tr> <tr> <td>W_rectangularity</td><td>Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.</td></tr> <tr> <td>W_SpotX and W_SpotY</td><td>Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used</td></tr> </table>	V_NumParticles	Number of particles that exceed the <i>minArea</i> limit.	W_ImageObjArea	Area (in pixels) for each particle.	W_ImageObjPerimeter	Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.	W_circularity	Ratio of the square of the perimeter to ($4*\pi*\text{objectArea}$). This value approaches 1 for a perfect circle.	W_rectangularity	Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.	W_SpotX and W_SpotY	Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used
V_NumParticles	Number of particles that exceed the <i>minArea</i> limit.												
W_ImageObjArea	Area (in pixels) for each particle.												
W_ImageObjPerimeter	Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.												
W_circularity	Ratio of the square of the perimeter to ($4*\pi*\text{objectArea}$). This value approaches 1 for a perfect circle.												
W_rectangularity	Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.												
W_SpotX and W_SpotY	Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used												

to define the position of a tag or annotation for a particle. Points can also be used as seed pixels for the associated *mark* method or for the ImageSeedFill operation.

W_xmin, W_xmax, W_ymin, W_ymax

Contain a single point for each particle defining an inscribing rectangular box with axes along the X and Y directions.

One of the following waves can be created depending on the /M specification. The waves are designed to be used as an overlay on the original image (using the explicit=1 mode of **ModifyImage**). **Note:** the additional time required to create these waves is negligible compared with the time it takes to generate the stats data.

M_ParticlePerimeter Masking image of particle boundaries. It is an unsigned char wave that contains 0 values for the object boundaries and 64 (i.e., NaN) for all other points.

M_ParticleArea Masking image of the area occupied by the particles. It is an unsigned char wave containing 0 values for the object boundaries and 64(=NaN) for all other points. It is also different from the input image in that particles smaller than the minimum size, specified by /A, are absent.

M_Particle Image of both the area and the boundary of the particles. It is an unsigned char wave that contains the value 16 for object area, the value 18 for the object boundaries and the value 64(=NaN) for all other points.

M_rawMoments Contains five columns. The first column is the raw sum of the x values for each particle, and the second column contains the sum of the y values. To obtain the average or “center” of a particle divide these values by the corresponding area. The third column contains the sum of x^2 , the fourth column the sum of y^2 , and the fifth column the sum of $x*y$. The entries of this wave are used in calculating a fit to an ellipse (using the /E flag).

When *imageMatrix* is a 3D wave, the different results are packed into a single 2D wave M_3DParticleInfo, which consists of one row and 11 columns for each particle. Columns are arranged in the following order: minRow, maxRow, minCol, maxCol, minLayer, maxLayer, xSeed, ySeed, zSeed, volume, and area. Use `Edit M_3DParticleInfo.1d` to display the results in a table with dimension labels describing the different columns.

Flags

- /A=*minArea* Specifies a minimum area as a threshold that must be exceeded for a particle to be counted (e.g., use *minArea*=0 to find single pixel particles). The minimum area is measured in pixels; its default value is *minArea*=5.
- /D=*dataWave* Has no effect when used with the *mark* method.
- /E Specify a wave from which the minimum, maximum, and total particle intensity are sampled when used with the stats keyword. *dataWave* must be of the same dimensions as the input binary image *imageMatrix*. It can be of any real numeric type. Results are returned in the waves W_IntMax, W_IntMin, and W_IntAvg.
- /F Calculates an ellipse that best fits each particle. The equivalent ellipse is calculated by first finding the moments of the particle (i.e., average x-value, average y-value, average x^2 , average y^2 , and average $x*y$), and then requiring that the area of the ellipse be equal to that of the particle. The resulting ellipses are saved in the wave M_Moments. When *imageMatrix* is a 2D wave, the results returned in M_Moments are the columns: the X-center of the ellipse, the Y-center of the ellipse, the major axis, the minor axis, and the angle (radians) that the major axis makes with the X-direction. When *imageMatrix* is a 3D wave, the results in M_Moments include the sum of the X, Y, and Z components as well as all second order permutations of their products. They are arranged in the order: sumX, sumY, sumZ, sumXX, sumYY, sumZZ, sumXY, sumXZ, and sumYZ.
- /F Fills 2D particles having internal holes and adjusts their area measure for the removal of holes. Internal boundaries around the holes are also eliminated. When the boundary of the particle consists of thin elements that cannot be traversed as a single closed path which passes each boundary pixel only once, the particle will not be filled. Note that filling particles may increase execution time considerably and on some images it may require large amount of memory. It is likely that a more efficient approach would be

	to preprocess the binary image and remove holes using morphology operations. This flag is not supported when <i>imageMatrix</i> is a 3D wave.
/L=(row,col)	Specifies a 2D particle location in connection with the mark method. (row, col) is a seed value corresponding to any pixel inside the particle. If the seed belongs to the particle boundary, the particle will not be filled. This flag is not supported when <i>imageMatrix</i> is a 3D wave.
/M=markerVal	Use this flag with the stats mode for 2D images. See stats keyword for a full description of the following waves: markerVal=0: No marker waves. markerVal=1: M_ParticlePerimeter. markerVal=2: M_ParticleArea. markerVal=3: M_Particle. This flag does not apply to 3D waves.
/MAXA=maxArea	Specifies an upper limit of the area of an acceptable particle when used with the stats keyword. The area is measured in pixels and the default value of <i>maxArea</i> is the number of pixels in the image. In 3D the maximum value applies to the number of voxels.
/NSW	Creates the marker wave (see /M flag) but not the particle statistics waves when used with the stats keyword. This should reduce execution time in images containing many particles.
/P=plane	Specifies the plane when operating on a single layer of a 3D wave.
/Q	Quiet flag, does not report the number of particles to the history window.
/R=roiWave	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as <i>imageMatrix</i> . The ROI itself is defined by the entries or pixels in the <i>roiWave</i> with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When <i>imageMatrix</i> is a 3D wave, <i>roiWave</i> can be either a 2D wave (matching the number of rows and columns in <i>imageMatrix</i>) or it can be a 3D wave that must have the same number of rows, columns and layers as <i>imageMatrix</i> . When using a 2D <i>roiWave</i> with a 3D <i>imageMatrix</i> the ROI is understood to be defined by <i>roiWave</i> for each layer in the 3D wave. See ImageGenerateROIMask for more information on creating 2D ROI waves.
/U	Saves the wave M_ParticleMarker as an 8-bit unsigned instead of the default 16-bit when used with the mark keyword.
/W	Creates boundary waves W_BoundaryX, W_BoundaryY, and W_BoundaryIndex for a 2D <i>imageMatrix</i> wave. W_BoundaryX and W_BoundaryY contain the pixels along the particle boundaries. The boundary of each particle ends with a NaN entry in both waves. Each entry in W_BoundaryIndex is the index to the start of a new particle in W_BoundaryX and W_BoundaryY, so that you can quickly locate the boundary of each particle. When there are holes in particles, the entries in W_BoundaryX and W_BoundaryY start with the external boundary followed by all the internal boundaries for that particle. There are no index entries for internal boundaries. This flag is not supported when <i>imageMatrix</i> is a 3D wave.

Details

Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the **ImageSeedFill** operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. ImageSeedFill also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in ImageAnalyzeParticles.

Examples

Convert a grayscale image (blobs) into a proper binary input:

```
ImageThreshold/M=4/Q/I blobs
```

Get the statistics on the thresholded image of blobs and create an image mask output wave for the perimeter of the particles:

```
ImageAnalyzeParticles/M=1 stats M_ImageThresh
```

Display an image of the blobs with a red overlay of the perimeter image:

```
NewImage/F blobs; AppendImage M_ParticlePerimeter
ModifyImage M_ParticlePerimeter explicit=1, eval={0,65000,0,0}
```

See Also

The **ImageThreshold**, **ImageGenerateROIMask**, **ImageSeedFill**, and **ModifyImage** operations. For more usage details see **Particle Analysis** on page III-310.

ImageBlend

ImageBlend [/A=*alpha* /W=*alphaWave*] *srcWaveA*, *srcWaveB* [, *destWave*]

The ImageBlend operation takes two RGB images (3D waves) in *srcWaveA* and *srcWaveB* and computes the alpha blending so that

$$destWave = srcWaveA * (1 - alpha) + srcWaveB * alpha$$

for each color component. If *destWave* is not specified, the result is saved in the current data folder in the wave M_alphaBlend.

The source and destination waves must be of the same data types and the same dimensions. The *alphaWave*, if used, must be a single precision (SP) float wave and it must have the same number of rows and columns as the source waves.

Flags

/A= <i>alpha</i>	Specifies a single alpha value for the whole image
/W= <i>alphaWave</i>	Single precision wave that specifies an alpha value for each pixel.

ImageBoundaryToMask

ImageBoundaryToMask width=*w*, height=*h*, xwave=*xwavename*, ywave=*ywavename* [, *scalingWave=scalingWaveName*, [*seedX=xVal*, *seedY=yVal*]]

The ImageBoundaryToMask operation scan-converts a pair of XY waves into an ROI mask wave.

Parameters

height = <i>h</i>	Specifies the mask height in pixels.
scalingWave = <i>scalingWaveName</i>	2D or 3D wave that provides scaling for the mask. If specified, the scaling of the first two dimensions of <i>scalingWave</i> are copied to M_ROIMask, and both the X and Y waves are assumed to describe pixels in the scaled domain.
seedX = <i>xVal</i>	Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedY.
seedY = <i>yVal</i>	Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedX.
width = <i>w</i>	Specifies the mask width in pixels.
xwave = <i>xwavename</i>	Name of X wave for mask region.
ywave = <i>ywavename</i>	Name of Y wave for mask region.

Details

ImageBoundaryToMask generates an unsigned char 2D wave named M_ROIMask, of dimensions specified by width and height. The wave consists of a background value of zero and 255 where the x, y waves have been scan converted.

The x and y waves can be of any type. However, if the waves describe disjoint regions there must be at least one NaN entry in each wave corresponding to the discontinuity, which requires that you use either single or double precision waves. The values stored in the waves must correspond to zero-based integer pixel values.

If the x and y waves include a vertex that lies outside the mask rectangle, the offending vertex is moved to the boundary before the associated line segment is scan converted.

ImageEdgeDetection

If you want to obtain a true ROI mask in which closed regions are filled, you can specify the seedX and seedY keywords. The ROI mask is set with zero outside the boundary of the domain and 1 everywhere inside the domain.

Examples

```
Make/O/N=(100,200) src=gnoise(5)           // create a test image
SetScale/P x 500,1,"", src;DelayUpdate    // give it some funny scaling
SetScale/P y 600,1,"", src
Display; AppendImage src
Make/O/N=201 xxx,yyy                      // create boundary waves
xxx=550+25*sin(p*pi/100)                  // representing a close ellipse
yyy=700+35*cos(p*pi/100)
AppendToGraph yyy vs xxx
```

Now create a mask from the ellipse and scale it so that it will be appropriate for src:

```
ImageBoundaryToMask ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src
```

To generate an ROI masked filled with 1 in a region defined by a seed value and the boundary curves:

```
ImageBoundaryToMask
ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src,seedx=550,seedy=700
```

ImageEdgeDetection

ImageEdgeDetection [flags] Method imageMatrix

The ImageEdgeDetection operation performs one of several standard image edge detection operations on the source wave *imageMatrix*. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageEdges. The edge detection methods produce binary images on output (the background is set to 0 and the edges to 255). This is due, in most cases to a thresholding performed in the final stage. Except for the case of marr and shen detectors, you can use the /M flag to specify a method for automatic thresholding (see **ImageThreshold** /M flag).

Parameters

Method selects type of edge detection. *Method* is one of the following names:

canny	Canny edge detector uses smoothing before edge detection and thresholding. You can optionally specify the threshold using the /T flag and the smoothing factor using /S.
frei	Calculates the Frei-Chen edge operator (see Pratt p. 503) using only the row and column filters.
kirsch	Kirsch edge detector (see Pratt p. 509). Performs convolution with 8 masks calculating gradients.
marr	Marr-Hildreth edge detector. Performs two convolutions with Laplacian of Gaussian and then detects zero crossings. Use the /S flag to define the width of the convolution kernel.
prewitt	Calculates the Prewitt compass gradient filters. Returns the result for the largest filter response.
roberts	Calculates the square root of the magnitude squared of the convolution with the Robert's row and column edge detectors.
shen	Shen-Castan optimized edge detector. Supposed to be effective in the presence of noise. The flags that modify this operation are: /F for the threshold ratio (0.9 by default), /S for smoothness factor (0.9 by default), /W for window width (default is 10), /H for thinning factor which by default is 1.
sobel	Sobel edge detector using convolutions with row and column edge gradient masks (see Pratt p. 501).

Flags

/F=fraction	Determines the threshold value for the shen algorithm by starting from the histogram of the image and choosing a threshold such that <i>fraction</i> specifies the portion of the image pixels whose values are below the threshold. Valid values are in the interval ($0 < fraction < 1$).
/H=thinning	Thins edges when used with shen edge detector. By default the thinning value is 1. Higher values produce thinner edges.
/I	Inverts the output, i.e., sets the edges to 255 and the background to 0.
/M=threshMethod	See the ImageThreshold automatic methods for obtaining a threshold value. Methods 1, 2, 4 and 5 are supported in this operation. If you use <i>threshMethod</i> = -1, threshold is not applied.

	If you want to apply your own thresholding algorithm, use /M=6 to bypass the thresholding completely. The wave M_RawCanny contains the result regardless of any other flags you may have used.
/N	Sets the background level to 64 (i.e., NaN)
/O	Overwrites the source image with the output image.
/R= <i>roiSpec</i>	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by entries/pixels whose values are 0. Pixels outside the ROI can be any nonzero value. The ROI does not have to be contiguous and can be any arbitrary shape. See ImageGenerateROIMask for more information on creating ROI waves. In general, the <i>roiSpec</i> has the form { <i>roiWaveName</i> , <i>roiFlag</i> }, where <i>roiFlag</i> can take the following values: <i>roiFlag</i> =0: Set pixels outside the ROI to 0. <i>roiFlag</i> =1: Set pixels outside the ROI as in original image. <i>roiFlag</i> =2: Set pixels outside the ROI to NaN (=64). By default <i>roiFlag</i> is set to 1 and it is then possible to use the /R flag using the abbreviated form /R= <i>roiWave</i> .
/S= <i>smoothVal</i>	Specifies the standard deviation or the width of the smoothing filter. By default the operation uses 1. Larger values require longer computation time. In the shen operation the default value is 0.9 and the valid range is (0 < <i>smoothVal</i> < 1).
/T= <i>thresh</i>	Sets a manual threshold for any method above that uses a single threshold. This is faster than using /M.
/W= <i>width</i>	Specifies window width when used in the shen operation. By default width is set to 10 and it is clipped to 49.

References

Pratt, William K., *Digital Image Processing*, John Wiley, New York, 1991.

ImageFileInfo

ImageFileInfo [/P=*pathName*] *fileNameStr*

The ImageFileInfo operation supplies information about an image file without having to open the file and load the data into Igor.

ImageFileInfo works with the following file types: PICT, TIFF, GIF, JPEG, PNG, Targa, QuickTime, and BMP.

ImageFileInfo requires QuickTime. The operation will fail (V_flag=0) if you request information for a file format that is not supported by QuickTime.

Parameters

fileNameStr specifies the image file for which information is needed.

The file of interest is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

Flags

/P=*pathName* Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.

Variables

ImageFileInfo returns information in the following variables:

ImageFilter

S_path	File system path to the selected file.
V_BPP	Number of bits per pixel. A value of 40 means 8-bit grayscale; all other values are bits per pixel.
V_flag	1 if operation was successful, 0 otherwise.
V_frameCount	Number of movie frames.
V_numCols	Height of the image.
V_numImages	Number of images in the file. Only supports TIFF files that contain multiple images.
V_numRows	Width of the image.
V_quality	Image compression quality in hexadecimal: codecLosslessQuality = 0x00000400 codecMaxQuality = 0x000003FF codecMinQuality = 0x00000000 codecLowQuality = 0x00000100 codecNormalQuality = 0x00000200 codecHighQuality = 0x00000300

ImageFilter

ImageFilter [*flags*] **Method** *dataMatrix*

The ImageFilter operation is identical to **MatrixFilter**, accepting the same parameters and flags, with the exception of the additional features described below.

Parameters

Method selects the filter type. *Method* is one of the following names:

avg3d	<i>nxn</i> <i>nxn</i> average filter for 3D waves.
gauss3d	<i>nxn</i> <i>nxn</i> gaussian filter for 3D waves.
hybridmedian	Implements ranking pixel values between two groups of pixels in a 5x5 neighborhood. The first group includes horizontal and vertical lines through the center, the second group includes diagonal lines through the center, and both groups include the center pixel itself. The resulting median value is the ranked median of both groups and the center pixel.
max3d	<i>nxn</i> <i>nxn</i> maximum rank filter for 3D waves.
median3d	<i>nxn</i> <i>nxn</i> median filter for 3D waves where <i>n</i> must be of the form 3^r (integer <i>r</i>), e.g., 3x3x3, 9x9x9 etc. The filter does not change the value of the voxel it is centered on if any of the filter voxels lies outside the domain of the data.
min3d	<i>nxn</i> <i>nxn</i> minimum rank filter for 3D waves.
point3d	<i>nxn</i> <i>nxn</i> point finding filter using normalized $(n^3 - 1) * \text{center-outer}$ for 3D waves.

Flags

/N= <i>n</i>	Specifies the filter size. By default <i>n</i> = 3. In most situations it will be useful to set <i>n</i> to an odd number in order to preserve the symmetry in the filters.
/O	Overwrites the source image with the output image. Used only with the hybridmedian filter, which does not automatically overwrite the source wave.

Details

You can operate on 3D waves using the 3D filters listed above. These filters are extensions of the 2D filters available under **MatrixFilter**. The avg3d, gauss3d, and point3d filters are implemented by a 3D convolution that uses an averaging compensation at the edges.

MatrixConvolve for information about convolving your own 3D kernels.

References

Russ, J., *Image Processing Handbook*, CRC Press, 1998.

ImageFocus

ImageFocus [*flags*] *stackWave*

The ImageFocus operation creates in focus image(s) from a stack of images that contain in and out of focus regions. It computes the variance in a small neighborhood around each pixel and then takes the pixel value from the plane in which the highest variance is found.

Flags

/ED= <i>edpth</i>	Sets the effective depth in planes. For example, an effective depth of one means that it computes the best focus for each plane using a stack of three planes, which includes the current plane and any one adjacent plane above and below it. Does not affect the default method (/METH=0).
/METH= <i>method</i>	Specifies the calculation method. <i>method</i> =0: Computes a single plane output for the stack (default). <i>method</i> =1: Computes the best image for each plane using /ED.
/Q	Quiet mode; no output to history window.
/Z	No error reporting.

See Also

Chapter III-11, **Image Processing** contains links to and descriptions of other image operations.

ImageGenerateROIMask

ImageGenerateROIMask [/W=*winName*/E=*e*/I=*i*] *imageInstance*

The ImageGenerateROIMask operation creates a Region Of Interest (ROI) mask for use with other ImageXXX commands. It assumes the top (or /W specified) graph contains an image and that the user has drawn shapes using Igor's drawing tools in a specific manner.

ImageGenerateROIMask creates an unsigned byte mask matrix with the same x and y dimensions and scaling as the specified image. The mask is initially filled with zeros. Then the drawing layer, progFront, in the graph is scanned for suitable fillable draw objects. The area inside each shape is filled with ones unless the fill mode for the shape is set to erase in which case the area is filled with zeros.

Flags

/E= <i>e</i>	Changes value used for the exterior from the default zero values to <i>e</i> .
/I= <i>i</i>	Changes value used for the interior from the default one values to <i>i</i> .
/W= <i>winName</i>	Looks for the named graph window or subwindow containing appropriate image masks drawn by the user. If /W is omitted, ImageGenerateROIMask uses the top graph window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Suitable objects are those that can be filled (rectangles, ovals, etc.) and which are plotted in axis coordinate mode specified using the same axes by which the specified image instance is displayed. Objects plotted in plot relative mode are also used. However, this is not recommended because it will give correct results only if the image exactly fills the plot rectangle. If you use axis coordinate mode then you can zoom in or out as desired and the resulting mask will still be correct.

Note that the shapes can have their fill mode set to none. This still results in a fill of ones. This is to allow the drawn ROI to be visible on the graph without obscuring the image. However cutouts (fills with erase mode) will obscure the image.

Note also that nonfill drawing objects are ignored. You can use this fact to create callouts and other annotations.

In a future version of Igor, we may create a new drawing layer in graphs dedicated to ROIs.

The mask generated is named M_ROIMask and is generated in the current data folder.

Variable V_flag is set to 1 if the top graph contained draw objects in the correct layer and 0 if not. If 0 then the M_ROIMask wave was not generated.

Examples

```
Make/O/N=(200,400) jack=x*y; NewImage jack; ShowTools
SetDrawLayer ProgFront
SetDrawEnv linefgc=(65535,65535,0),fillpat=0,xcoord=top,ycoord=left,save
DrawRect 63.5,79.5,140.5,191.5
DrawRRect 61.5,206.5,141.5,280.5
SetDrawEnv fillpat=-1
DrawOval 80.5,169.5,126.5,226.5
ImageGenerateROIMask jack
NewImage M_ROIMask
AutoPositionWindow/E
```

See Also

For another example see **Generating ROI Mask** on page III-313.

ImageHistModification

ImageHistModification [*flags*] *imageMatrix*

The ImageHistModification operation performs a modification of the image histogram and saves the results in the wave M_ImageHistEq. If /H is not specified, the operation is a simple histogram equalization of *imageMatrix*. If /H is specified, the operation attempts to produce an image with a histogram close to *waveName*. If /A is specified, the operation performs an adaptive histogram equalization. *imageMatrix* is a wave of any noncomplex numeric type. Adaptive histogram equalization applies only to 2D waves and the other parts apply to both 2D and 3D waves.

Flags

- /A Performs an adaptive histogram equalization by subdividing the image into a minimum of 4 rectangular domains and using interpolation to account for the boundaries between adjacent domains. When the /C flag is specified with contrast factor greater than 1, this operation amounts to contrast-limited adaptive histogram equalization. By default the operation divides the image into 8 horizontal and 8 vertical regions. See /H and /V.
- /B=*bins* Specifies the number of *bins* used with the /A flag. If not specified, this value defaults to 128.
- /C=*cFactor* Specifies a contrast factor (or clipping value) above which pixels are equally distributed over the whole range. *cFactor* must be greater than 1, in the limit as *cFactor* approaches 1 the operation is a regular adaptive histogram equalization. **Note:** this flag is used only with the /A flag.
- /H=*hRegions* Specifies the number of horizontal subdivisions to be used with the /A feature. Note, the number of image pixels in the horizontal direction must be an integer multiple of *hRegions*.
- /I Extends the standard histogram equalization by using 2^{16} bins instead of 2^8 when calculating histogram equalization. This feature does not apply to the adaptive histogram equalization (/A flag).
- /O Overwrites the source image. If this flag is not specified, the resulting image is saved in the wave M_ImageHistEq.
- /R=*roiSpec* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries whose values are 0. Regions outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape.
- In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:
- roiFlag*=0: Set pixels outside the ROI to 0.
 - roiFlag*=1: Set pixels outside the ROI as in original image (default).
 - roiFlag*=2: Set pixels outside the ROI to NaN (=64).
- By default *roiFlag* is set to 1 and it is then possible to use the /R flag with the abbreviated form /R=*roiWave*. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave which must have the same number of rows, columns, and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix*, the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.

- See **ImageGenerateROIMask** for more information on creating ROI waves.
- /V=vRegions* Specifies the number of vertical subdivisions to be used with the */A* flag. The number of image pixels in the horizontal direction must be an integer multiple of *vRegions*. If the image dimensions are not divisible by the number of regions that you want, you can pad the image using **ImageTransform padImage**.
- /W=waveName* Specifies a 256-point wave that provides the desired histogram. The operation will attempt to produce an image having approximately the desired histogram values. This flag does not apply to the adaptive histogram equalization (*/A* flag)

See Also

The **ImageGenerateROIMask** and **ImageTransform** operations for creating ROIs. For examples see **Histograms** on page III-307 and **Adaptive Histogram Equalization** on page III-291.

ImageHistogram

ImageHistogram [*flags*] *imageMatrix*

The ImageHistogram operation calculates the histogram of *imageMatrix*. The results are saved in the wave *W_ImageHist*. If *imageMatrix* is an RGB image stored as a 3D wave, the resulting histograms for each color plane are saved in *W_ImageHistR*, *W_ImageHistG*, *W_ImageHistB*. There are no restrictions on data type of *imageMatrix*.

Flags

- /I* Calculates a histogram with 65536 bins evenly distributed between the minimum and maximum data values. The operation first finds the extrema and then calculates the bins and the resulting histogram. Data can be a 2D wave of any type including float or double.
- /P=plane* Restricts the calculation of the histogram to a specific plane when *imageMatrix* is a non RGB 3D wave.
- /R=roiWave* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (*/b/u*) that has the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries of pixels in the *roiWave* with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave that must have the same number of rows, columns and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix* the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.
- See **ImageGenerateROIMask** for more information on creating 2D ROI waves.
- /S* Computes the histogram for a whole 3D wave possibly subject to 2D or 3D ROI masking. The */S* and */P* flags are mutually exclusive.

Details

The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or */P* or */I*) you could alternatively use the **Histogram** operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of *imageMatrix* is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the */I* flag to increase the number of bins to 65536, which may be useful for unsigned short (*/W/U*) data.

See Also

The **ImageHistModification** and **ImageGenerateROIMask** operations. For examples see **Histograms** on page III-307.

ImageInfo

ImageInfo(*graphNameStr*, *imageWaveNameStr*, *instanceNumber*)

The ImageInfo function returns a string containing a semicolon-separated list of information about the specified image in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

imageWaveNameStr contains either the name of a wave displayed as an image in the named graph, or an image instance name (wave name with “#n” appended to distinguish the nth image of the wave in the graph). You might get an image instance name from the **ImageNameList** function.

If *imageWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as an image in a graph. Set *instanceNumber* to 1 for information about the second image of the wave, etc. If *imageWaveNameStr* is “”, then information is returned on the *instanceNumber*th image in the graph.

If *imageWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *imageWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *imageWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
RECREATION	List of keyword commands as used by ModifyImage command. The format of these keyword commands is: <i>keyword (x)=modifyParameters;</i>
XAXIS	X axis name.
XWAVE	X wave name if any, else blank.
XWAVEDF	The full path to the data folder containing the X wave or blank if there is no X wave.
YAXIS	Y axis name.
YWAVE	Y wave name if any, else blank.
YWAVEDF	The full path to the data folder containing the Y wave or blank if there is no Y wave.
ZWAVE	Name of wave containing Z data used to calculate the image plot.
ZWAVEDF	The full path to the data folder containing the Z data wave.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyImage ”, replace the “x” with the name of a image plot (“data#1” for instance) and then **Execute** the resultant string as a command.

Examples

The following command lines create a very unlikely image display. If you did this, you would most likely want to put each image plot on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack=sin(x/5)+cos(y/4)
Display;AppendImage jack
AppendImage/T/R jack
```

This example shows the image information for the second image plot of the wave “jack” (which has an instance number of 1) displayed in the top graph:

```
Print ImageInfo("", "jack", 1)[0,64]           // error if you print all
```

Prints something like the following in the history area:

```
XAXIS:top;YAXIS:right;XWAVE:;XWAVEDF:;YWAVE:;YWAVEDF:;ZWAVE:jack;
```

ImageInterpolate

ImageInterpolate [*flags*] *Method* *srcwave*

The ImageInterpolate operation interpolates the source *srcWave* and stores the results in the wave M_InterpolatedImage in the current data folder.

Parameters

Method selects type of interpolation. *Method* is one of the following names:

Affine2D Performs an affine transformation on *srcWave* using parameters specified by the /APRM flag. The transformation applies to a general combination of rotation, scaling, and translation represented by a 3x3 matrix

$$M = \begin{bmatrix} r_{11} & r_{12} & tx \\ r_{21} & r_{22} & ty \\ 0 & 0 & w \end{bmatrix}$$

The upper 2x2 matrix is a composite of rotation and scaling, *tx* and *ty* are composite translations and *w* is usually 1. It computes the dimensions of the output wave and then uses the inverse transformation and bilinear interpolation to compute the value of each output pixel. When an output pixel does not map back into the source domain it is set to the user-specified background value. It supports 2D and 3D input waves. If *srcWave* is a 3D wave it applies on a layer by layer basis.

Bilinear Performs a bilinear interpolation subject to the specified flag. You can use either the /F or /S flag, but not both.

Kriging Uses Kriging to generate an interpolated matrix from a sparse data set. Kriging calculates interpolated values for a rectangular domain specified by the /S flag. The Kriging parameters are specified via the /K flag.

Kriging is computed globally for a single user-selected variogram model. If there are significant spatial variances within the domain occupied by the data, you should consider subdividing the domain along natural boundaries and use a single variogram model in each subdivision.

If there are N data points, the algorithm first computes the NxN matrix containing the distances between the data and then inverts an associated matrix of similar size to compute the result for the selected variogram model. Because inversion of an NxN matrix can be computationally expensive, you should consider restricting the calculation to regions that are similar to the range implied by the variogram. Such an approach can also be justified in the sense that the local interpolation should not be affected by a remote datum.

Note: Kriging does not support data containing NaNs or INFs. Wave scaling has no effect.

Pixelate Creates a lower resolution (pixelated image) of *srcWave* by averaging the pixels inside rectangles specified by /PXSZ flag. The results are saved in the wave M_PixelatedImage in the current data folder. The computed wave has the same numeric type as *srcWave* and the same number of layers. The number of rows and the number of columns of the new image are obtained by integer division of the original number by the respective size of the averaging rectangle and adding one more pixel for any remainder.

Resample Computes a new image based on the selected interpolation function and transformation parameters. Set the interpolation function with the /FUNC flag. Use the /TRNS flag to specify transformation parameters for grayscale images, or /TRNR, /TRNG, and /TRNB for the red, green, and blue components, respectively, of RGB images. M_InterpolatedImage contains the output image in the current data folder.

There are currently two transformation functions: the first magnifies an image and the second applies a radial polynomial sampling. The radial polynomial affects pixels based on their position relative to the image center. A linear polynomial reproduces the same image. Any nonlinear terms contribute to distortion (or correction thereof).

Spline Computes a 2D spline interpolation for 2D matrix data. The degree of the spline is specified by the /D flag.

Voronoi Generates an interpolated matrix from a sparse data set (*srcWave* must be a triplet wave) using Voronoi polygons. It calculates interpolated values for a rectangular domain as specified by the /S flag. It first computes the Delaunay triangulation of X, Y locations in the Z=0 plane (assuming that X, Y positions occupy a convex domain in the plane). It then uses the Voronoi dual to interpolate the Z values for X and Y pairs from the grid defined by the /S flag. The

computed grid may exceed the bounds of the convex domain defined by the triangulation. Interpolated values for points outside the convex domain are set to NaN or the value specified by the /E flag. Use the /I flag to iterate to finer triangulation by subdividing the original triangles into smaller domains. Each iteration increases computation time by approximately a factor of two, but improves the smoothness of the interpolation.

If you have multiple sets of data in which X,Y locations are unchanged, you can use the /STW flag to store one triangulation and then use the /PTW flag to apply the precomputed triangulation to a new interpolation. To use this option you should use the Voronoi keyword first with a triplet wave for *srcWave* and set *xn = x0* and *yn = y0*. The operation creates the wave *W_TriangulationData* that you use in the next triangulation with a 1D wave as *srcWave*. For example:

```
ImageInterpolate/STW/S={0,1,0,1,1,1} Voronoi myTripletWave
ImageInterpolate/PTW=W_TriangulationData Voronoi my1DZWave
```

Voronoi interpolation is similar to what can be accomplished with the **ContourZ** function except that it does not require an existing contour plot, it computes the whole output matrix in one call, and it has the option of controlling the subdivision iterations.

XYWaves Performs bilinear interpolation on a matrix scaled using two X and Y 1D waves (specified by /W). The interpolation range is defined by /S. The data domain is defined between the centers of the first and last pixels (X in this example):

```
xmin=(xWave[0]+xWave[1])/2
xmax=(xWave[last]+xWave[last-1])/2
```

Values outside the domain of the data are set to NaN. The interpolation is contained in the *M_InterpolatedImage* wave, which is single precision floating point or double precision if *srcWave* is double precision.

Warp Performs image warping interpolation using a two step algorithm. Warps the image based on the relative positions of source and destination grids. The warped image has the same size as the source image. The source and destination grids are each specified by a pair of X and Y waves. All grid waves must have the same number of points and correspond to pixel positions within the image. Grid waves must not include any NaNs or INFs. Wave scaling is ignored.

Flags

/APRM={*r11,r12,tx,r21,r22,ty,w,background*}

Sets elements of the affine transformation matrix and the background value.

/D=*splineDeg*

Specifies the spline degree with the Spline method. The default spline degree is 2. Supported values are 2, 3, 4, and 5.

/E=*outerValue*

Assigns *outerValue* to all points outside the convex domain of the Delaunay triangulation. By default *outerValue* = NaN.

/F={*fx,fy*}

Calculates a bilinear interpolation of all the source data. Here *fx* is the sampling factor for the X-direction and *fy* is the sampling factor in the Y-direction. The output number of points in a dimension is *factor*(number of data intervals) + 1*. The number of data intervals is one less than the number of points in that dimension.

For example, if *srcWave* is a 2x2 matrix (you have a single data interval in each direction) and you use /F={2,2}, then the output wave is a 3x3 matrix (i.e., 2x2 intervals) which is a factor of 2 of the input. Sampling factors can be noninteger values.

/FUNC=*funcName* Specifies the interpolation function. *funcName* can be:

nn Nearest neighbor interpolation uses the value of the nearest neighbor without interpolation. This is the fastest function.

bilinear Bilinear interpolation uses the immediately surrounding pixels and computes a linear interpolation in each dimension. This is the second fastest function.

cubic Cubic polynomial (photoshop-like) uses a 4x4 neighborhood value to compute the sampled pixel value.

spline Spline smoothed sampled value uses a 4x4 neighborhood around the pixel.

sinc Slowest function using a 16x16 neighborhood.

/I=*iterations*

Specifies the number of times the original triangulation is subdivided with the Voronoi interpolation method. By default the Voronoi interpolation computes the original triangulation without subdivision.

/K={*model*, *nugget*, *sill*, *range*}

Specifies the variogram parameters for kriging using standard notation, models are expressed in terms of the nugget value C_0 , sill value C_0+C_1 , and range a .

model Selects the variogram model. Values and models are:

- 1: Spherical. $\gamma(h) = C_0 + C_1 \cdot (3h \llbracket a - 0.5 \cdot h^2 \rrbracket^2)$
- 2: Exponential. $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot h \llbracket a \rrbracket])$
- 3: Gaussian. $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot (h \llbracket a \rrbracket)^2])$

nugget Specifies the lowest value in the variogram.

sill Specifies the maximum (plateau) value in the variogram range the characteristic length of the different variogram models.

Wave scaling has no effect on kriging calculations.

/PTW=*tWave*

Uses a previous triangulation wave with Voronoi interpolation. *tWave* will be the wave saved by the /STW flag. You can't use a triangulation wave that was computed and saved on a different computer platform.

/PXSZ={*nx*, *ny*}

Specifies the size of the averaging rectangle in pixels. Here *nx* is the number of rows and *ny* is the number of columns that are averaged to yield a single output pixel.

/S={*x0,dx,xn,y0,dy,yn*}

Calculates a bilinear interpolation of a subset of the source data. Here *x0* is the starting point in the X-direction, *dx* is the sampling increment, *xn* is the end point in the X-direction and the corresponding values for the Y-direction. If you can set *x0* equal to *xn* the operation will compute the triangulation but not the interpolation

/STW

Saves the triangulation information in the wave W_TriangulationData in the current data folder. W_TriangulationData can only be used on the computer platform where it was created.

/SV

Saves the Voronoi interpolation in the 2D wave M_VoronoiEdges, which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle containing the convex domain.

/TRNS={*transformFunc*,*p1*,*p2*,*p3*,*p4*}

Determines the mapping between a pixel in the destination image and the source pixel. *transformFunc* can be:

scaleShift Sets image scaling which could be anamorphic if the X and Y scaling are different.

radialPoly Corrects both color as well as barrel and pincushion distortion. In *radialPoly* the mapping from a destination pixel to a source pixel is a polynomial in the pixel's radius relative to the center of the image.

A source pixel, *sr*, satisfies the equation: $sr = a \cdot r + b \cdot r^2 + c \cdot r^3 + d \cdot r^4$, where *r* is the radius of a destination pixel having an origin at the center of the destination image.

The corresponding parameters are:

<i>transformFunc</i>	<i>p1</i>	<i>p2</i>	<i>p3</i>	<i>p4</i>
scaleShift	xOffset	xScale	yOffset	yScale
radialPoly	a	b	c	d

/U=uniformScale Calculates a bilinear interpolation of all the source data as with the */F* flag but with two exceptions: A single uniform scale factor applies in both dimensions, and the scale factor applies to the number of points — not the intervals of the data.

/W={xWave, yWave} Provides the scaling waves for XYWaves interpolation. Both waves must be monotonic and must have one more point than the corresponding dimension in *srcWave*. The waves contain values corresponding to the edges of data points in *srcWave*, so that the X value at the first data point is equal to $(xWave[0] + xWave[1]) / 2$.

Flags for Warp

/dgrx=wave Sets the wave containing the destination grid X data.
/dgry=wave Sets the wave containing the destination grid Y data.
/sgrx=wave Sets the wave containing the source grid X data.
/sgry=wave Sets the wave containing the source grid Y data.
/WM=im Sets the interpolation method for warping an image.

<i>I</i>	Method
1	Fast selection of original data values.
2	Linear interpolation.
3	Smoothing interpolation (slow)

Details

When computing Bilinear or Spline interpolation *srcWave* can be a 2D or a 3D wave. When *srcWave* is a 3D wave the interpolation is computed on a layer by layer basis and the result is stored in a corresponding 3D wave. When the interpolation method is Kriging or Voronoi, *srcWave* is a 2D triplet wave (3-column wave) where each row specifies the X, Y, Z values of a datum. *srcWave* can be of any real data type. Results are stored in the wave *M_InterpolatedImage*. If *srcWave* is double precision so is *M_InterpolatedImage*; otherwise *M_InterpolatedImage* is a single precision wave.

ImageLineProfile

ImageLineProfile [*flags*] *xWave*=*xwave*, *yWave*=*ywave*, *srcwave*=*srcwave* [, *width*=*value*, *widthWave*=*wWave*]

The ImageLineProfile operation provides sampling of a source image along an arbitrary path specified by the two waves: *xWave* and *yWave*. The arbitrary path is made of line segments between every two consecutive vertices of *xWave* and *yWave*. In each segment the profile is calculated at a number of points (profile points) equivalent to the sampling density of the original image (unless the */V* flag is used). Both *xWave* and *yWave* should have the same scaling as *srcWave*. If *srcWave* does not have the same scaling in both dimensions you should remove the scaling to compute an accurate profile.

At each profile point, the profile value is calculated by averaging samples along the normal to the profile line segment. The number of samples in the average is determined by the keyword *width*. The operation actually averages the interpolated values at *N* equidistant points on the normal to profile line segment, with $N = 2(\text{width} + 0.5)$. Samples outside the domain of the source image do not contribute to the profile value.

The profile values are stored in the wave `W_ImageLineProfile`. The actual locations of the profile points are stored in the waves `W_LineProfileX` and `W_LineProfileY`. When the averaging width is greater than zero, the operation can also calculate at each profile point the standard deviation of the values sampled for that point (see `/S` flag). The results are then stored in the wave `W_LineProfileStdv`. When using this operation on 3D RGB images, the profile values are stored in the three-column waves `M_ImageLineProfile` and `M_LineProfileStdv` respectively.

Parameters

`srcwave=srcwave` Specifies the image for which the line profile is evaluated. The image may be a 2D wave of any type or a 3D wave or RGB data.

`xWave=xwave` Specifies the wave containing the x coordinate of the line segments along the path.

`yWave=ywave` Specifies the wave containing the y coordinate of the line segments along the path.

`width=value` Specifies the width (diameter) in pixels (need not be an integer value) in a direction perpendicular to the path over which the data is interpolated and averaged for each path point. If you do not specify width or use `width=0`, only the interpolated value at the path point is used.

`widthWave=wWave` Specifies the width of the profile (see definition above) on a segment by segment basis. `wWave` should be a 1D wave that has the same number of entries as `xWave` and `yWave`. If you provide a `widthWave` any value assigned with the `width` keyword is ignored. All values in the wave must be positive and finite.

Flags

`/P=plane` Specifies which plane (layer) of a 3D wave is to be profiled. By default `plane=-1` and the profiles are of either the single layer of a 2D wave or all three layers of a 3D RGB wave. Use `plane=-2` if you want to profile all layers of a 3D wave.

`/S` Calculates standard deviations for each profile point.

`/SC` Saves `W_LineProfileX` and `W_LineProfileY` using the X and Y scaling of `srcWave`.

`/V` Calculate profile points only at the vertices of `xWave` and `yWave`.

Examples

```
Make/N=(50, 50) sampleData
sampleData = sin((x-25) / 10) * cos((y-25) / 10)
NewImage sampleData
Make/n=2 xTrace={0,50} ,yTrace={20,20}
ImageLineProfile srcWave=sampleData, xWave=xTrace, yWave=yTrace
AppendtoGraph/T yTrace vs xTrace
Display W_ImageLineProfile
```

See Also

For additional examples see **ImageLineProfile** on page III-307.

ImageLoad

ImageLoad [*flags*] [*fileNameStr*]

The **ImageLoad** operation loads an image file into an Igor matrix wave. See the `/T` flag for a list of supported image file types.

ImageLoad requires QuickTime to load certain types of images. QuickTime 4.x or newer is recommended.

Parameters

The file to be loaded is specified by *fileNameStr* and `/P=pathName` where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

ImageLoad

Flags

/C=count	Specifies which images to load from a multi-image TIFF file. It loads and stores images as individual waves in the current data folder. By default, it loads only a single image (i.e., /C=1). Use /C=-1 to load all images into a single 3D wave (images must be either 8-, 16-, or 32-bits/pixel for this option). If you specify a <i>count</i> that exceeds the number of images in the file, it will load all images beginning with the starting image. See also the /S flag and examples.
/G	Displays the loaded image.
/LR3D	Loads a partial range of a TIFF stack into a 3D wave (see also /C and /S).
/N=baseName	Stores the waves using <i>baseName</i> identically for the wave name. Only when <i>baseName</i> conflicts with an existing wave name will a numeric suffix be appended to the new wave names. If you do not specify <i>baseName</i> , ImageLoad will use the name of the file as a base name.
/O	Overwrites an existing wave with the same name. If /O is omitted and there is an existing wave with the same name, a numerical suffix will be appended to the image name.
/P=pathName	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/Q	Quiet mode; suppresses insertion of loading info into the history area.
/RAT	Read All Tags reads all of the tags in a TIFF file into one or more waves. It creates a data folder named "Tag <i>n</i> " (with a numeric suffix, <i>n</i> , starting from zero) for each loaded image. When reading multiple images from a stack TIFF file it will create a corresponding number of data folders. Each data folder contains a Text wave named T_Tags, which contains 5 columns and as many rows as there are TIFF tags associated with the specified Image File Directory (IFD). The first column contains the tag number, the second contains the tag description, the third contains the tag type, the fourth contains the tag length, and the fifth contains either the value of the tag or a statement identifying the name of the wave in which the data was stored. For example, a simple tag that contains a single value has the form:

Num	Desc	Type	Length	Value
256	IMAGEWIDTH	4	1	2560

A tag that contains more data, such as an array of values has the form:

Num	Desc	Type	Length	Value
273	STRIPOFFSETS	4	-120	tifTag273

Here the Length field is negative (-1*realLength) and the Value field contains the name of the wave tifTag273 which contains the array of strip offsets.

When the Value field consists of ASCII characters it is stored in the T_Tags wave itself. All other types are stored in a wave in the same Tag data folder.

Private tags are usually designated by negative tag numbers. If their data type is anything other than ASCII, they are saved in separate waves.

/RTIO	Reads tag information only from a TIFF file. (This flag is similar to the /RAT flag but it does not load the images.) If you are loading a stack of images you can use the /C and /S flags to obtain tags from a specific range of images.
/T=type	Identifies what kind of image file to load. <i>type</i> is one of the following image file formats:

<i>type</i>	Loads this Image Format
any	Any graphic file type.
bmp	PC bitmap file.
gif	GIF file.
jpeg	JPEG file.
photoshop	PhotoShop file.

	<i>type</i>	Loads this Image Format
	pict	Macintosh picture file.
	png	PNG file.
	rpng	Raw PNG file (see Details).
	sgi	Silicon Graphics file.
	sunraster	Sun Raster file.
	targa	Targa file.
	tiff	Any TIFF file (see also Special Notes Regarding TIFF Files).
	If you do not specify <i>type</i> , Igor will make a guess based on the file type (<i>Macintosh</i>) or file name extension (<i>Windows</i>). An error will be reported if Igor is unable to guess the image type.	
/S=start	Specifies the starting image in TIFF files that contain multiple images. By default, /S=0, so if you want to load all images just use /C=-1.	
/Z	no error reporting.	

Details

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

ImageLoad sets the following variables:

V_flag	Set to 1 if the image was successfully loaded or to 0 otherwise.
S_fileName	Set to the name of the file that was loaded.
V_numImages	Set to the number of images in the file. Use this variable only with TIFF files.
S_path	Set to the file system path to the folder containing the file.
S_waveNames	Set to a semicolon-separated list of the names of loaded waves.

S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When loading a rpng format PNG image, the wave will be either 8- or 16-bit unsigned integer format with 1 to 4 planes. PNG images with physical units will produce waves with X and Y units of meters. If a PNG image has a color table, ImageLoad will create two waves: a main image wave with 1 plane and a color table wave of the same name but with a "_pal" suffix (if the name is too long, it will create a wave named *PNG_pal* instead).

Special Notes Regarding TIFF Files

The ImageLoad operation reads data from the named TIFF file into waves. The operation supports 1-, 8-, 16- and 24-bit TIFF files. In case of 1-bit/pixel the data is converted into a 1 byte/pixel (/B/U wave). Images of 16-bits/pixel are read into /W/U waves. We note that 16-bit format is not part of the TIFF 6.0 specification but it is used extensively by scientific camera manufacturers. Images of 24-bits/pixel are read into 3D RGB waves.

When a TIFF file contains multiple images (stack), you can read all images into waves or you can specify a particular image or a range of images that you would like to read. To read the complete stack specify -1 as the image count and all images will be saved into a single 3D wave where each image is a sequential plane. This is appropriate only for images that are 8- or 16-bits/pixel deep. If the depth of the image is other than 8- or 16-bits/pixel you should read the images into separate waves.

If you have a TIFF file that is not read correctly by this operation (e.g., 4-bits/pixel), you may be able to read the file using QuickTime. To do so, make sure that the file name does not contain ".tif" or ".tiff" suffix (and on the Macintosh change its file type from 'TIFF' to '????'). You can then load the file using the "Any" file designation and the file will be read by QuickTime resulting in an RGB image wave.

Examples

Reading TIFF files containing a stack of images:

```
ImageLoad /C=8/S=10/T=Tiff // Creates 8 waves starting from image #10 (zero based)
ImageLoad/C=-1/S=10/T=TIFF // Loads all the images ignoring the /S flag.
                          // The images are stored in a single 3D wave.
ImageLoad/C=-1/T=TIFF/RTIO // Does not load the images but reads all tags.
NewDataFolder/O/S tmp      // Gets the number of images and cleans up
ImageLoad/C=-1/T=TIFF/RTIO
```

Print V_numImages
KillDataFolder :

For loading graphic objects, see **Pictures** on page III-405. The **ImageSave** operation for saving waves as image files.

ImageMorphology

ImageMorphology [*flags*] Method *imageMatrix*

The ImageMorphology operation performs one of several standard image morphology operations on the source *imageMatrix*. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageMorph. The operation applies only to waves of type unsigned byte. All ImageMorphology methods except for watershed use a structure element. The structure element may be one of the built-in elements (see /E flag) or a user specified element.

Erosion, Dilation, Opening, and Closing are the only methods supported for a 3D *imageMatrix*.

Parameters

Method is one of the following names:

BinaryErosion	Erodes the source binary image using a built-in or user specified structure element (see /E and /S flags).
BinaryDilation	Dilates the source binary image using a built-in or user specified structure element (see /E and /S flags).
Closing	Performs the closing operation (dilation followed by erosion). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent, which means that there is no point of executing it more than once.
Dilation	Performs a dilation of the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
Erosion	Erodes the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
Opening	Performs an opening operation (erosion followed by dilation). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent which means that there is no point of executing it more than once.
TopHat	Calculates the difference between the eroded image and dilated image using the same structure element.
Watershed	Calculates the watershed regions for grayscale or binary image. Use the /N flag to mark all nonwatershed lines as NaNs. The /L flag switches from using 4 neighboring pixels (default) to 8 neighboring pixels.

Flags

/E=*id* Uses a particular built in structure element. The following are the built-in structure element. The following are the built-in structure elements; make sure to use the appropriate id for the dimensionality of *imageMatrix*:

<i>id</i>	Element	Origin	Shape
1	2x2	(0,0)	square (default)
2	1x3	(1,1)	row (in 3x3 square)
3	3x1	(1,1)	column (in 3x3 square)
4	3x3	(1,1)	cross (in 3x3 square)
5	5x5	(2,2)	circle (in 5x5 square)
6	3x3	(1,1)	full 3x3 square
200	2x2x2	(1,1,1)	symmetric cube
202	2x2x2	(1,1,1)	2 voxel column in Y direction

<i>id</i>	Element	Origin	Shape
203	2x2x2	(1,1,1)	2 voxel column in X direction
204	2x2x2	(1,1,1)	2 voxel column in Z direction
205	2x2x2	(1,1,1)	XY plane
206	2x2x2	(1,1,1)	YZ plane
207	2x2x2	(1,1,1)	XZ plane
300	3x3x3	(1,1,1)	symmetric cube
301	3x3x3	(1,1,1)	symmetric ball
302	3x3x3	(1,1,1)	3 voxel column in Y direction
303	3x3x3	(1,1,1)	3 voxel column in X direction
304	3x3x3	(1,1,1)	3 voxel column in Z direction
305	3x3x3	(1,1,1)	XY plane
306	3x3x3	(1,1,1)	YZ plane
307	3x3x3	(1,1,1)	XY plane
500	5x5x5	(2,2,2)	symmetric cube
501	5x5x5	(2,2,2)	symmetric ball
700	7x7x7	(3,3,3)	symmetric cube
701	7x7x7	(3,3,3)	symmetric ball

Note that this flag has no effect on watershed calculations.

/I= *iterations*

Repeats the operation the specified number of *iterations*.

/L

Uses 8-connected neighbors instead of 4.

/N

Sets the background level to 64 (= NaN).

/O

Overwrites the source wave with the output.

/R=*roiSpec*

Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape. See **ImageGenerateROIMask** for more information on creating ROI waves.

In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.

roiFlag=1: Set pixels outside the ROI as in original image.

roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default *roiFlag* is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=*roiWave*.

/S= *seWave*

Specifies your own structure element. There are no limitations on the size of the structure element and you can use the /X and /Y flags to specify the origin of your structure element.

/W= *whiteVal*

Sets the white value in the binary image if it is different than 255. The black level is assumed to be zero.

/X= *xOrigin*

Specifies the X-origin of a user-defined structure element starting at 0. If you do not use this flag Igor sets the origin to the center of the specified structure element.

/Y= *yOrigin*

Specifies the Y-origin of a user defined structure element starting at 0. If you do not use this flag Igor sets the origin to the center of the specified structure element.

/Z= *zOrigin*

Specifies the Z-origin of the element for 3D structure elements. If you do not use this flag Igor sets the origin to the center of the specified structure element.

ImageNameList

Examples

If you would like to apply a morphological operation to a wave whose data type is not an unsigned byte and you wish to retain the wave's dynamic range, you can use the following approach:

```
Function scaledErosion(inWave)
    Wave inWave
    WaveStats/Q inWave
    Variable nor=255/(V_max-V_min)
    Duplicate/O inWave,tmp
    Redimension/b/u tmp
    tmp=nor*(inWave-V_min)
    ImageMorphology/E=5 Erosion tmp
    Wave M_ImageMorph
    inWave=M_ImageMorph/nor
    KillWaves/Z tmp,M_ImageMorph
End
```

The **ImageGenerateROIMask** operation for creating ROIs. For details and usage examples see **Morphological Operations** on page III-303 and **Particle Analysis** on page III-310.

ImageNameList

ImageNameList(*graphNameStr*, *separatorStr*)

The ImageNameList function returns a string containing a list of image names in the graph window or subwindow identified by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

separatorStr should contain a single character such as "," or ";" to separate the names.

An image name is defined as the name of the 2D wave that defines the image with an optional #ddd suffix that distinguishes between two or more images that have the same wave name. Since the image name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely image display. If you did this, you would want to put each image on different axes, and arrange the axes such that they don't overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,'jack # 2';
Display;AppendImage jack
AppendImage/T/R jack
AppendImage 'jack # 2'
AppendImage/T/R 'jack # 2'
Print ImageNameList("",";")
prints jack;jack#1;jack # 2;jack # 2#1;
```

Another command related to images and waves: **ImageNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

ImageNameToWaveRef

ImageNameToWaveRef(*graphNameStr*, *imageNameStr*)

The ImageNameToWaveRef function returns a wave reference to the 2D wave corresponding to the given image name in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The image is identified by the string in *imageNameStr*, which could be a string determined using **ImageNameList**. Note that the same image name can refer to different waves in different graphs.

ImageRegistration

ImageRegistration [*flags*][*testMask=testMaskWave*] [*refMask=refMaskWave*]
testWave=imageWave1, *refWave=imageWave2*

The ImageRegistration operation adjusts the test image wave, *testWave*, to match the reference image wave, *refWave*, possibly subject to auxiliary mask waves. The registration may involve offset, rotation, scaling or skewing. Image data may be in two or three dimensions. ImageRegistration is designed to find accurate registration for relatively small variation on the order of a few degrees of rotation and a few pixels offset between the reference and test images. All the input waves are expected to be single precision float (SP) so you may have to redimension your images before using ImageRegistration.

Parameters

- refMask=refMaskWave* Specifies an optional ROI wave used to mask *refWave*. Omit *refMask* to use all of the *refWave*.
 The wave must have the same dimensions as *refWave*. *refMask* is a single precision floating point wave with nonzero entries marking the "ON" state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.
- refWave=imageWave2* Specifies the name of the reference image wave used to adjust *testWave*.
- testMask=testMaskWave* Specifies an optional ROI wave used to mask *testWave*. Omit *testMask* to use all of the *testWave*.
 The wave must have the same dimensions as *refWave*. *testMask* is a single precision floating point wave with nonzero entries marking the "ON" state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.
- testWave=imageWave1* Specifies the name of the image wave that will be adjusted to match *refWave*.
testMaskWave and *refMaskWave* are optional ROI waves. The waves must have the same dimensions as *testWave* and *refWave* respectively. They must be single precision floating point waves with nonzero entries marking the "ON" state. If you need to include the whole region described by *testWave* or the whole region described by *refWave* you can omit the respective mask wave

Flags

- /ASTP=val* Sets the adaptation step for the Levenberg-Marquardt algorithm. Default value is 4.
- /BVAL=val* Enables clipping and sets the background values to which masked out voxels of the test data will be set.
- /CONV=val* Sets the convergence method.
val=0: Gravity, use if the difference between the images is only in translation. This option is frequently useful as a first step when the test and reference data are too far apart for accurate registration. The result of this registration is then passed to a subsequent ImageRegistration with */CONV=1*.
val=1: Marquardt.
- /FLVL=val* Specifies the finest level on which the optimization is to be performed.
 If this is the same as */PRDL*, then only the coarsest registration calculation is done.
 If */FLVL=1* (default), then the full multiresolution pyramid is processed. You can use this flag to terminate the computation at a specified coarseness level greater than 1.
- /GRYM* Optimizes the gray level scaling factor.
 It is sometimes dangerous to let the program adjust for gray levels because in some situations it might result in a null image.

/GRYR	Renders output using the gray scaling parameter. This is more meaningful if the operation computes the optimal gray scaling (see /GRYM).
/GWDT={sx,sy,sz}	Sets the three fields to the half-width of a Gaussian window that is used to smooth the data when computing the default masks. Defaults are {1,1,1}. See /REFM and /TSTM for more details.
/INTR=val	Sets the interpolation method. val=0: Nearest neighbor. Used when registering the center of gravity of the test and reference images. val=1: Trilinear. val=2: Tricubic (default).
/ISOS	Optimizes the isometric scaling. This option is inappropriate if voxels are not cubic.
/ISR	Computes the multiresolution pyramid with isotropic size reduction. If the flag is not specified, the size reduction is in the XY plane only.
/MING=val	Sets the minimum gain at which the computations will stop. Default value is zero, but you can use a slightly larger value to stop the iterations earlier.
/MSKC=val	Sets mask combination value. During computation the masks for the test data and the mask for the reference data are also transformed. This flag determines how the two masks are to be combined. The registration criteria are computed for the combination of the two masks. val=0: or. val=1: nor. val=2: and (default). val=3: nand. val=4: xor. val=5: nxor.
/PRDL=depth	Specifies the depth of the multiresolution pyramid. The finest level is <i>depth</i> =1. Each level of the pyramid decreases the resolution by a factor of 2. By default, the pyramid <i>depth</i> =4, which corresponds to a resolution reduction by a factor of $2^{(depth-1)}=8$. The algorithm starts by computing the first registration on large scale features in the image (deepest level of the pyramid). It then makes small corrections to the registration at each consecutive pyramid level. For best results, the coarsest representation the data should be between 30 and 60 pixels on a side. For example, for an image that is <i>H</i> by <i>V</i> pixels, you should choose the depth such that $H/2^{(depth-1)} \approx 30$.
/Q	Quiet mode; no messages printed in the history window.
/REFM=val	Sets the reference mask. val=0: To leave blank and then every pixel is taken into account. val=1: Value will be set if a valid reference mask is provided. val=2: The reference mask is computed (default). When computing the reference mask it is assumed that brighter features are more important. This is done by using a low pass filter on the data (using the parameters in /GWDT) which is then converted into a binary mask. Note that you do not need to specify /REFM=1 if you are providing a reference mask wave. See also /TSTM.
/ROT={rotX,rotY,rotZ}	Determines if optimization will take into account rotation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding rotation parameter. Defaults are {0,0,1}, which are the appropriate for rotating images.
/SKEW={skewX,skewY,skewZ}	Determines if optimization will take into account skewness about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding skewness parameter. Defaults are {0,0,0}. Note that skewing and rotation or isometric scaling are mutually exclusive operations.

/STRT= <i>val</i>	Sets the first value of the adaptation parameter in the Levenberg-Marquardt algorithm. The default value of this parameter is 1.
/TRNS={ <i>transX,transY,transZ</i> }	Determines if optimization will take into account translation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding translation parameter. Defaults are {1,1,0}, which are appropriate for finding the X and Y translations of an image.
/TSTM= <i>val</i>	Sets the test mask. <i>val</i> =0: To leave blank and then every pixel is taken into account. <i>val</i> =1: This value will be set if a valid reference mask is provided. <i>val</i> =2: The reference mask is computed. This is the default value. The test image mask is computed in the same way as the reference image mask (see /REFM) using the same set of smoothing parameters. Note that you do not need to specify /TSTM=1 if you are providing a test mask wave.
/ZMAN	Modifies the test and reference data by subtracting their mean values prior to optimization.

Details

ImageRegistration will register images that have sufficiently similar features. It will not work if key features are too different. For example, ImageRegistration can handle two images that are rotated relative to each other by a few degrees, but cannot register images if the relative rotation is as large as 45 degrees. The algorithm is capable of subpixel resolution but it does not handle large variations between the test image and the reference image. If the centers of the two images are too far from each other, you should first try ImageRegistration using /CON=0 to remove the translation offset before proceeding with a finer registration of details.

The algorithm is based on an iterative processing that proceeds from coarse to fine detail. Optimization uses a modified Levenberg-Marquardt algorithm and produces an affine transformation for the relative rotation and translation as well as for isometric scaling and contrast adjustment. The algorithm is most effective with square images where the center of rotation is not far from the center of the image.

When using gravity for convergence, skew parameters can't be evaluated (only translation is supported). Skew and isoscaling are mutually exclusive options. Mask waves are defined to have zero entries for pixels outside the region of interest and nonzero entries otherwise. If a mask is not provided, every pixel is used.

ImageRegistration creates the waves M_RegOut and M_RegMaskOut, which are both single precision waves. In addition, the operation creates the wave W_RegParams which stores 20 double precision registration parameters. M_RegOut contains the transformed (registered) test image and M_RegMaskOut contains the transformed mask (which is not affected by mask combination). ImageRegistration ignores wave scaling; images are compared and registered based on pixel values only.

The results printed in the history include:

dx, dy, dz	translation offsets measured in pixels.
<i>aij</i>	Elements in the skewing transformation matrix.
phi	Rotation angle in degrees about the X-axis. Zero for 2D waves.
tht	Rotation angle in degrees about the Y-axis. Zero for 2D waves.
psi	Rotation angle in degrees about the Z-axis.
det	Absolute value of determinant of the skewing matrix (<i>aij</i>).
err	Mean square error defined as

$$\frac{1}{N} \sum (x_i - y_i)^2,$$

where x_i is the original pixel value, y_i the computed value, and N is the number of pixels.

snr	Signal to noise ratio in dB. It is given by:
-----	--

$$10 \cdot \log \left(\frac{\sum inVal^2}{\sum (x_i - y_i)^2} \right).$$

Some of these parameters are stored in the wave W_RegParams in the following order: dx, dy, dz, all 9 elements of *aij*, Phi, tht, psi, originX, originY, and originZ. The last three elements correspond to the center of image which accounts for translation offsets and possible skewing.

References

The ImageRegistration operation is based on an algorithm described by:

Thévenaz, P., and M. Unser, A Pyramid Approach to Subpixel Registration Based on Intensity, *IEEE Transactions on Image Processing*, 7, 27-41, 1998.

ImageRemoveBackground

ImageRemoveBackground /R=roiWave [flags] srcWave

The ImageRemoveBackground operation removes a general background level, described by a polynomial of a specified order, from the image in *srcWave*. The result of the operation are stored in the wave *M_RemovedBackground*.

Flags

- /F Computes only the background surface fit. Will only store the resulting fit in *M_RemovedBackground*. This will not subtract the fit from the image.
- /O overwrites the original wave.
- /P=*polynomial order* Specifies the order of the polynomial fit to the background surface. If omitted, the order is assumed to be 1.
- /R=*roiWave* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u), which has the same number of rows and columns as the image wave. The ROI itself is defined by the entries / pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See **ImageGenerateROIMask** for more information on creating ROI waves.
- /W Specifies that polynomial coefficients are to be saved in the wave *W_BackgroundCoeff*.

Details

The identification of the background is done via the ROI wave. The ROI waves should consist of the value 1 where the user wants to designate a pixel as a background and 0 otherwise.

The operation first performs a polynomial fit to the points designated by the ROI wave using the specified polynomial order. A polynomial of order N corresponds to the function:

$$F_N(x,y) = \sum_{m=0}^N \sum_{n=0}^m c_{nm} x^{m-n} y^n.$$

Using the polynomial fit, a surface corresponding to the polynomial is subtracted from the source wave and the result is saved in *M_RemovedBackground*, unless the /O flag is used, in which case the original wave is overwritten.

Use the /W flag if you want polynomial coefficients to be saved in the *W_BackgroundCoeff* wave. Coefficients are stored in the same order as the terms in the sums above.

If you do not specify the polynomial order using the /P flag, the default order is 1, which means that the operation subtracts a plane (fitted to the ROI data) from the source image.

Note, if the image is stored as a wave of unsigned byte, short, or long, you might consider converting it into single precision (using **Redimension/S**) before removing the background. To see why this is important, consider an image containing a region of pixels equal to zero and subtracting a background plane corresponding to a nonconstant value. After subtraction, at least some of the pixels in the zero region should become negative, but because they are stored as unsigned quantities, they appear incorrectly as large values.

The **ImageGenerateROIMask** operation for creating ROIs. For examples see **Background Removal** on page III-314.

ImageRotate

ImageRotate [*flags*] *imageMatrix*

The ImageRotate operation rotates the image clockwise by *angle* (degrees). The resulting image is saved in the wave M_RotatedImage unless the /O flag is specified. The size of the resulting image depends on the angle of rotation. The portions of the image corresponding to points outside the domain of the original image are set to the default value 64 or the value specified by the /E flag. Note, you can also apply this operation to 3D waves of any data type.

Flags

- /A=*angle* Specifies the rotation angle measured in degrees in a clockwise direction. For rotations by exactly 90 degrees use /C or /W instead.
- /E= *val* Specifies the value for pixels that are outside the domain of the original image. By default pixels are set to 64. If you specify /E= (NaN) and your data is of type char, short, or long, the operation sets the external values to 64.
- /F Rotates image by 180 degrees.
- /H Flip the image horizontally.
- /O Overwrites the original image with the rotated image.
- /Q Quiet mode. Without this flag the operation writes warnings in the history window.
- /S Uses source image wave scaling to preserve scaling and relative locations of objects in the image for rotation angles that are multiples of 90 degrees.
- /V Flip the image vertically.
- /Z Ignore errors.

See Also

The **MatrixTranspose** operation.

ImageSave

ImageSave [*flags*] *waveName* [[*as*] *fileNameStr*]

The ImageSave operation saves the named wave as an image file.

ImageSave requires that QuickTime be installed on your computer, unless /D=16 and /T="tiff".

Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter or specify " " for *fileNameStr* or use the /I flag. The "as" keyword before *fileNameStr* is optional.

Flags

- /D=*depth* Specifies color depth in bits-per-pixel. Integer values of 1, 8, 16, 24, 32, and 40 are supported. A *depth* of 40 specifies 8-bit grayscale; a *depth* of 8 saves the file as 8-bits/pixel with a color lookup table.
- /F Saves the wave as single precision float. The image is not scaled. Applies only to TIFF files.
- /I Interactive mode. Forces ImageSave to display a Save File dialog, even if the file and folder location are fully specified.
- /O Overwrites the specified file if it exists. If /O is omitted and the file exists, ImageSave displays a Save File dialog.
- /P=*pathName* Specifies the folder in which to save the image file. *pathName* is the name of an existing symbolic path.

ImageSeedFill

/Q= <i>quality</i>	Specifies the quality of the compressed image. It is a number between 0 and 1, with 1 being the highest quality. This is only applicable when saving in formats with lossy compression. By default <i>quality</i> =1 for nonlossy image compression.
/S	Saves as stack. Applies only to 3D or 4D source waves saved as TIFF files.
/T= <i>fileType</i>	Specifies the type of file to be saved using Apple's file type codes.

<i>fileType</i>	Saved Image Format
8BPS	PhotoShop file.
BMPf	PC bitmap file.
JPEG	JPEG file.
PICT	Macintosh picture file.
PNGf	PNG file.
rpng	raw PNG file (see Details).
qtif	QuickTime file.
.SGI	Silicon Graphics file.
TPIC	Targa file.
TIFF	TIFF file.

	The character string is case sensitive. The default file types, used if /T is omitted, are 'pict' on the Macintosh and 'bmpf' on Windows.
/WT= <i>tagWave</i>	Saves TIFF files with file tags as specified by <i>tagWave</i> , which is a text wave containing of a row and 5 columns for each tag (see description of the /RAT flag under ImageLoad). It ignores any information in the second column but will write the tags sequentially (only in the first Image File Directory (IFD) if there is more than one image). If the fourth column contains a negative number, there must be a wave, whose name is given in the fifth column of <i>tagWave</i> , in the same data folder as <i>tagWave</i> . You must make sure that: (1) tag numbers are legal and do not conflict with any existing tags; (2) the data type and data size are consistent with the amount of data saved in external waves.
/Z	No error reporting.

Details

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

The rpng image format requires a wave in 8- or 16-bit unsigned integer format with 1 to 4 planes. Use one plane for grayscale, 3 planes for rgb color, and the extra plane for an alpha channel. If X or Y scaling is not unity, they both must be valid and must be either inches per pixel or meters per pixel. If the units are not inches they are taken to be meters.

If you are saving a wave in TIFF format and there is a mismatch between the specified saving depth (/D or /F flags) and the number type of the wave, the operation will normalize the data. For example, if you are saving an 8-bit image of a floating point wave, the operation will scale the data so it is in the range [0,255].

See Also

The **ImageLoad** operation for loading image files into waves.

ImageSeedFill

ImageSeedFill [*flags*] [*keyword*], seedX=*xLoc*, seedY=*yLoc*, target=*setValue*, srcWave=*srcImage*

The ImageSeedFill operation takes a seed pixel and fills a contiguous region with the target value, storing the result in the wave M_SeedFill. The filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). ImageSeedFill works on 2D and 3D waves.

Parameters

keyword is one of the following names:

<i>adaptive=</i> <i>factor</i>	<p>Invokes the adaptive algorithm where a pixel or voxel is accepted if, in addition, its value satisfies: $val - avg < factor \cdot stdv$.</p> <p>Here <i>val</i> is the value of the pixel or voxel in question, <i>avg</i> is the average value of the pixels or voxels in the neighborhood and <i>stdv</i> is the standard deviation of these values. By choosing a small <i>factor</i> you can constrain the acceptable values to be very close to the neighborhood average. A large <i>factor</i> allows for more deviation assuming that the <i>stdv</i> is greater than zero.</p> <p>This requirement means that a connected pixel has to be between the specified minimum and maximum value and satisfy the adaptive relationship. In most situations it is best to set wide limits on the minimum and maximum values and allow the adaptive parameter to control the local connectivity.</p>
<i>fillNumber=</i> <i>num</i>	Specifies the number, in the range 1 to 26, of voxels in each 3x3x3 cube that belong to the set. If <i>fillNumber</i> is exceeded, the operation fills the remaining members of the cube. If you do not specify this keyword, the operation does not fill the cube. Used only in the fuzzy algorithm.
<i>fuzzyCenter=</i> <i>fcVal</i>	Specifies the center value for the fuzzy probability with the fuzzy algorithm (see Details). The default value is 0.25. Its standard range is 0 to 0.5, although interesting results might be obtained outside this range.
<i>fuzzyProb=</i> <i>fpVal</i>	Specifies a probability threshold that must be met by a voxel to be accepted to the seeded set. The value must be in the range 0 to 1. The default value is 0.75.
<i>fuzzyScale=</i> <i>fsVal</i>	Determines if a voxel is to be considered in a second stage using fuzzy probability. <i>fsVal</i> must be nonzero in order to invoke the fuzzy algorithm. The scale is used in comparing the value of the voxel to the value of the seed voxel. The scale should normally be in the range 0.5 to 2.0.
<i>fuzzyWidth=</i> <i>fwVal</i>	Defines the width of the fuzzy probability distribution with the fuzzy algorithm (see Details). In most situations you should not need to specify this parameter. The default value is 1.
<i>min=</i> <i>minval</i>	Specifies the minimum value that is accepted in the seeded set. Not needed when using fuzzy algorithm.
<i>max=</i> <i>maxval</i>	Specifies the maximum value that is accepted to the seeded set. Not needed when using the fuzzy algorithm.
<i>seedP=</i> <i>row</i>	Specifies the integer row location of the seed pixel or voxel. This avoids roundoff issues when <i>srcWave</i> has wave scaling. You must provide either <i>seedP</i> or <i>seedX</i> with all algorithms. It is sometimes convenient to use this with cursors e.g., <i>seedP=pcsr(a)</i> .
<i>seedQ=</i> <i>col</i>	Specifies the integer column location of the seed pixel or voxel. This avoids roundoff difficulties when <i>srcWave</i> has wave scaling. You must provide either <i>seedQ</i> or <i>seedY</i> with all algorithms.
<i>seedR=</i> <i>layer</i>	Specifies the integer layer position of the seed voxel. When <i>srcWave</i> is a 3D wave you must use either <i>seedR</i> or <i>seedZ</i> .
<i>seedX=</i> <i>xLoc</i>	Specifies the pixel or voxel index. If <i>srcWave</i> has wave scaling, <i>seedX</i> must be expressed in terms of the scaled coordinate. This keyword or <i>seedP</i> is required with all algorithms.
<i>seedY=</i> <i>yLoc</i>	Specifies the pixel or voxel index. If <i>srcWave</i> has wave scaling, <i>seedY</i> must be expressed in terms of the scaled coordinate. This keyword or <i>seedQ</i> is required with all algorithms.
<i>seedZ=</i> <i>zLoc</i>	Specifies the voxel index. If <i>srcWave</i> has wave scaling, <i>seedZ</i> must be expressed in terms of the scaled coordinate. You must use this keyword or <i>seedR</i> whenever <i>srcWave</i> is 3D.
<i>srcWave=</i> <i>srcImage</i>	Specifies the source image wave.
<i>target=</i> <i>val</i>	Sets the value assigned to pixels or voxels that belonging to the seeded set.
Flags	
<i>/B=</i> <i>bValue</i>	Specifies the value assigned to pixels or voxels that do not belong to the fuzzy set.
<i>/C</i>	Uses 8-connectivity where a pixel can be connected to any one of its neighbors and with which it shares as little as a single boundary point. The default setting is 4-connectivity where pixels can be connected if they are neighbors along a row or a column. This has no effect in 3D, where 26-connectivity is the only option.
<i>/K=</i> <i>killCount</i>	Terminates the fill operation after <i>killCount</i> elements have been accepted.
<i>/O</i>	Overwrites the source wave with the output (2D only).

/R=roiWave Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u), that has the same number of rows and columns and layers as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See `ImageGenerateROIMask` for more information on creating ROI waves.

Details

In two dimensions, the operation takes a seed pixel, optional minimum and maximum pixel values and optional adaptive coefficient. It then fills a contiguous region (in a copy of the source image) with the target value. There are two algorithms for 2D seed fill. In direct seed fill (only min, max, seedX and seedY are specified) the filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). In adaptive fill, there is an additional condition for the pixel or voxel to be selected, which requires that the pixel value must be within the standard deviation of the average in the 3x3 (2D) or 3x3x3 (3D) nearest neighbors. If you do not specify the minimum and maximum values then the operation selects only values identical to that of the seed pixel.

In 3D, there are three available algorithms. The direct seed fill algorithm uses the limits specified by the user to fill the seeded domain. In adaptive seed fill the algorithm requires the limits as well as the adaptive parameter. It fills the domain by accepting only voxels that lie within the adaptive factor times the standard deviation of the immediate voxel neighborhood. To invoke the third algorithm you must set `fuzzyScale` to a nonzero value. The fuzzy seed fill uses two steps to determine if a voxel should be in the filled domain. In the first step the value of the voxel is compared to the seed value using the fuzzy scale. If accepted, it passes to the second stage where a fuzzy probability is calculated based on the number of voxels in the 3x3x3 cell which passed the first step together with the user-specified probability center (`fuzzyCenter`) and width (`fuzzyWidth`). If the result is greater than `fuzzyProb`, the voxel is set to belong to the filled domain.

If the */O* flag is not specified, the result is stored in the wave `M_SeedFill`.

If you specify a background value with the */B* flag, the resulting image consists of the background value and the target value in the area corresponding to the seed fill. Although the wave is now bi-level, it retains the same number type as the source image.

`ImageSeedFill` returns a “bad seed pixel specification” if the seed pixel location derived from the various keywords above satisfies one or more of the following conditions:

1. The computed integer pixel/voxel is outside the image.
2. The value stored in the computed integer pixel/voxel location does not satisfy the min/max or fuzzy conditions. This is the most common condition when `srcWave` has wave scaling. To avoid this difficulty you should use the keywords `seedP`, `seedQ`, and `seedR`.

Examples

Using `Cursor A` position and value to supply parameter inputs for a 2D `seedFill`:

```
ImageSeedFill seedx=pcsr(a),seedy=qcsr(a),min=zcsr(a),max=zcsr(a),target=0,srcwave=image0
```

Using the fuzzy algorithm for a 3D wave (**Warning:** command wrapped over two lines):

```
ImageSeedFill seedX=232,seedY=175,seedZ=42,target=1,fillnumber=10,fuzzycenter=.25,  
fuzzywidth=1,threshold=1,fuzzyprob=0.4,srcWave=ddd
```

See Also

For an additional example see **Seed Fill** on page III-312. To display the result of the operation for 3D waves it is useful to convert the 3D wave `M_SeedFill` into an array of quads. See **ImageTransform vol2surf**.

ImageSnake

ImageSnake [*flags*] *srcWave*

The `ImageSnake` operation creates or modifies an active contour/snake in the grayscale image `srcWave`. The operation iterates to find the “lowest total energy” snake. The energy is defined by a range of optional flags, each corresponding to an individual term in the total energy expression. Iterations terminate by reaching the maximum number of iterations, when the snake does not move between iterations or when the user aborts the operation.

Flags

/ALPH=alpha Sets the coefficient of the energy term arising from the “tightness” of the snake.
/BETA=beta Sets the coefficient of the energy term corresponding to curvature of the snake. A high value for beta makes the snake more rounded.

/DELT= <i>delta</i>	Sets the coefficient of the repulsion energy. A high value of <i>delta</i> keeps nonconsecutive snake points far from each other.
/EPS= <i>num</i>	Sets the maximum number of vertices which are allowed to move in one iteration. If the number of vertices which move during an iteration is smaller than <i>num</i> then iterations terminate.
/EXEF= <i>eta</i>	Sets the coefficient of the optional external energy component. By default this value is set to zero and there is no external energy contribution to the snakes energy. Note, this component is referred to as “external” because it is completely up to the user to specify both its coefficient and the value associated with each pixel. It should not be confused with what is called external snake energy in the literature, which usually applies to energy proportional to the gradient image (see /GAMM and /GRDI).
/EXEN= <i>wave</i>	Specify a wave that contains energy values that will be added to the snakes energy calculation. The wave must have the same dimensions as <i>srcWave</i> and must be single precision float. Each pixel value corresponds to user defined energy which will be multiplied by the /EXEF coefficient and added to the sum which the snake minimizes. Note that when /EXEF is set to zero this component is ignored. An external energy wave may be useful, for example, if you want to attract the snake to the picture boundaries. In that case you can set: <pre> Duplicate/O srcWave,extWave Redimension/S extWave Variable rows=DimSize(srcWave,0)-1 Variable cols=DimSize(srcWave,1)-1 extWave=(p==0 q==0 p==rows q==cols) ? 0:1 </pre>
/GAMM= <i>gamma</i>	Sets the coefficient of the energy term corresponding to the gradient. A high value of gamma makes the snake follow lines of high image gradient.
/GRDI= <i>gWave</i>	Specify the gradient image. This wave must have the same dimensions as <i>srcWave</i> and it must be single precision float. The wave corresponds to the quantity <code>abs(grad(gauss**srcWave))</code> , where grad is the gradient operator and ** denotes convolution of the source wave with a Gaussian kernel. It is best to run the operation the first time without specifying this wave. When the operation executes, it creates the wave <i>M_GradImage</i> which can then be used in subsequent executions of this operation. If you want to modify the wave to express some other form of energy that you want the operation to minimize, you should use the /EXEN and /EXEF flags.
/ITER= <i>iterations</i>	Sets the maximum number of iterations. Convergence can be achieved if the value specified by /EPS is met. You can also terminate the process earlier via a user abort (Command-'. Macintosh or Ctrl-Break Windows).
/N= <i>snakePts</i>	Specify the number of vertices in the snake or the number of snake points. Note that if you are providing snake waves in /SX and /SY, you do not need to specify this flag. If you do not specify this flag the default value is 40.
/SIG= <i>sigma</i>	Sets the size of the Gaussian kernel that is used to convolve the input image when creating the gradient image. Note that you do not need to use this flag if you provide a gradient image. <i>sigma</i> is 3 by default. You can use larger odd integers for larger Gaussian kernels which would correspond to a stronger blur.
/START={ <i>centerX, centerY, radius</i> }	Sets the starting snake to be a circle with the given center and radius. If you use this flag you should also provide the number of snake points using the /N flag.
/STEP= <i>pixels</i>	Sets the maximum radius of search. By default the radius of the search is 6 pixels and the search follows a clockwise pattern from radius of 1 pixel to maximum radius specified by this flag. Note: the search radius should be smaller than the dimension of a typical feature in the image. If the radius is larger the snake may encompass more than one object. Larger radius is also less efficient because many of the pixels in that range would result in a snake that crosses itself and hence get rejected in the process.
/SX= <i>xSnake</i>	Provide an X-wave for the starting snake. You must also provide an appropriate Y-wave using /SY.
/SY= <i>ySnake</i>	Provide a Y-Wave for the starting snake. Must work in combination with /SX.
/UPDM= <i>mode</i>	Sets the update mode using any combination of the following:
/Q	Quiet mode; don't print information in the history.

Value	Update
0	Once when the operation terminates.
1	Once at the end of every iteration.
2	Once after every snake vertex moves.
4	Once for every search position.

/Z Don't report any errors.

Details

A snake is a two-dimensional, usually closed, path drawn over an image. The snake is described by a pair of XY waves consisting of N vertices (sometimes called "snake elements" or "snaksels"). In this implementation it is assumed that the snake is closed so that the last point in the snake is connected to the first. Snakes are used in image segmentation, when you want to automatically select a contiguous portion of the plane based on some criteria. Unlike the classic contours, snakes do not have to follow a constant level. Their structure (or path) is found by associating the concept of energy with every snake configuration and attempting to find the configuration for which the associated energy is a minimum. The search for a minimum energy configuration is usually time consuming and it strongly depends on the format of the energy function and the initial conditions (as defined by the starting snake). The operation computes the energy as a sum of the following 5 terms:

1. The coefficient alpha times a sum of absolute deviations from the average snake segment length. This term tends to distribute the vertices of the snake at even intervals.
2. The coefficient beta times a sum of energies associated with the curvature of the snake at each vertex.
3. The coefficient gamma times a sum of energies computed from the negative magnitude of the gradient of a Gaussian kernel convolved with the image. This term is usually referred to in the literature as the external energy and usually drives the snake to follow the direction of high image gradients.
4. The coefficient delta times a repulsion energy. Repulsion is computed as an inverse square law by adding contributions from all vertices except the two that are immediately connected to each vertex. This energy term is designed to make sure that the snake does not fold itself into "valleys".
5. The coefficient eta times the sum of values corresponding to the positions of all snake vertices in the wave you provide in /EXEN.

The energy calculation skips all terms for which the coefficient is zero. In addition there is a built-in scan which adds a very high penalty for configurations in which the snake crosses itself.

ImageStats

ImageStats [/M=val/P=planeNumber]/R=roiWave imageWave

ImageStats [/M=val/P=planeNumber]/G={startP,endP,startQ,endQ} imageWave

ImageStats [/M=val/P=planeNumber]/GS={sMinRow,sMaxRow,sMinCol,sMaxCol} imageWave

ImageStats [/M=val/P=planeNumber] imageWave

The ImageStats operation calculates wave statistics for specified regions of interest in a matrix wave. The operation applies to image pixels whose corresponding pixels in the ROI wave are set to zero. It does not print any results in the history area.

Flags

/BEAM Computes the average, minimum, and maximum pixel values in each layer of a 3D wave and 2D ROI. Output is to waves W_ISBeamAvg, W_ISBeamMax, and W_ISBeamMin in the current data folder. Use /RECT to improve efficiency for simple ROI domains. V_ variable results correspond to the last evaluated layer of the 3D wave. Do not use /G, /GS, or /P with this flag. Set /M=1 for maximum efficiency.

/G={startP,endP,startQ,endQ} Specifies the corners of a rectangular ROI. When this flag is used an ROI wave is not required. This flag requires that startP ≤ endP and startQ ≤ endQ. When the parameters extend beyond the image area, the command will not execute and V_flag will be set to -1. You should therefore verify that V_flag=0 before using the results of this operation.

/GS={sMinRow,sMaxRow,sMinCol,sMaxCol}	Specifies a rectangular region of interest in terms of the scaled image coordinates. Each one of the 4 values will be translated to an integer pixel using truncation.
	This flag, /G, and an ROI specification are mutually exclusive.
/M=val	Calculates the average and locates the minimum and the maximum in the ROI when /M=1. This will save you the computation time associated with the higher order statistical moments.
/P=planeNumber	Restricts the calculation to a particular layer of a 3D wave. By default, <i>planeNumber</i> = -1 and only the first layer of the wave is processed.
/R=roiWave	Specifies a region of interest (ROI) in the image. The ROI is defined by a wave of type unsigned byte (/b/u), which has the same number of rows and columns as the image wave. The ROI itself is defined by the entries /pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See ImageGenerateROIMask for more information on creating ROI waves.
/RECT={minRow, maxRow, minCol, maxCol}	Limits the range of the ROI to a rectangular pixel range with /BEAM. It does not affect complex-valued wave statistics.

Details

The image statistics are returned via the following variables:

V_adev	Average deviation of pixel values.
V_avg	Average of pixel values.
V_kurt	Kurtosis of pixel values.
V_min	Minimum pixel value.
V_minColLoc	Specifies the location of the column in which the minimum pixel value was found or the first eligible column if no single column was found.
V_minRowLoc	Specifies the location of the row in which the minimum pixel value was found or the first eligible row if no single minimum was found.
V_max	Maximum pixel value.
V_maxColLoc	Specifies the location of the column in which the maximum pixel value was found or the first eligible column if no single column was found.
V_maxRowLoc	Specifies the location of the row in which the maximum pixel value was found or the first eligible row if no single maximum was found.
V_npnts	Number of points in the ROI.
V_rms	Root mean squared of pixel values.
V_sdev	Standard deviation of pixel values.
V_skew	Skewness of pixel values.

Most of these statistical results are similarly defined as for the WaveStats operation. WaveStats will be more convenient to use when calculating statistics for an entire wave.

The **ImageGenerateROIMask** and **WaveStats** operations. **ImageStats** on page III-307.

ImageThreshold

ImageThreshold [flags] imageMatrix

The ImageThreshold operation converts a grayscale *imageMatrix* into a binary image. The operation supports all data types. However, the source wave must be a 2D matrix. If *imageMatrix* contains NaNs, the pixels corresponding to NaN values are mapped into the value 64. The values for the On and Off pixels are 255 and 0 respectively. The resulting image is stored in the wave M_ImageThresh.

Flags

/C	Calculates the correlation coefficient between the original image and the image generated by the threshold operation. The correlation value is printed to the history window (unless the /Q flag is specified), it is also stored in the variable V_correlation.
/I	Inverts values written to the image, i.e., sets to zero all pixels above threshold.

ImageTransform

<i>/M= method</i>	<p>Specifies the thresholding method. The calculated value will be printed to the history window (unless <i>/Q</i> is specified) and stored in the variable <i>V_threshold</i>.</p> <p><i>method=1</i>: Automatically calculate a threshold value using an iterative method.</p> <p><i>method=2</i>: Image histogram is a simple bimodal distribution.</p> <p><i>method=3</i>: Adaptive thresholding. Evaluates threshold based on the last 8 pixels in each row, using alternating rows. Note that this method is not supported when used as part of the operation ImageEdgeDetection.</p> <p><i>method=4</i>: Fuzzy thresholding using entropy as the measure for “fuzziness”.</p> <p><i>method=5</i>: Fuzzy thresholding using a method that minimizes a “fuzziness” measure involving the mean gray level in the object and background.</p> <p>By default <i>method=0</i>, in which case you must use the <i>/T</i> flag to specify a manually selected threshold.</p>
<i>/N</i>	Sets the background level to 64 (i.e., NaN).
<i>/O</i>	Overwrites the original image with the calculated threshold image.
	If you do not specify the <i>/O</i> flag, the threshold image is written into the wave <i>M_ImageThresh</i> .
<i>/R=roiSpec</i>	<p>Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (<i>/b/u</i>). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape. See ImageGenerateROIMask for more information on creating ROI waves.</p> <p>In general, the <i>roiSpec</i> has the form <i>{roiWaveName, roiFlag}</i>, where <i>roiFlag</i> can take the following values:</p> <p><i>roiFlag=0</i>: Set pixels outside the ROI to 0.</p> <p><i>roiFlag=1</i>: Set pixels outside the ROI as in original image.</p> <p><i>roiFlag=2</i>: Set pixels outside the ROI to NaN (=64).</p> <p>By default <i>roiFlag</i> is set to 1 and it is then possible to use the <i>/R</i> flag using the abbreviated form <i>/R=roiWave</i>.</p>
<i>/T=thresh</i>	Sets the threshold value.
<i>/W= Twave</i>	Sets the threshold intervals. Each interval is specified by a pair of values in the wave <i>Twave</i> . The first element in each pair is the low value and the second element is the high value. Pixel values that lie outside all the specified intervals are set to 0.

For usage examples see **Threshold Examples** on page III-292. The **ImageGenerateROIMask** and **ImageEdgeDetection** operations.

ImageTransform

ImageTransform [*flags*] *Method imageMatrix*

The ImageTransform operation performs one of a number of transformations on *imageMatrix*. The result of using most keywords is a new wave stored in the current data folder. Most flags in this operation are exclusive to the keywords in which they are mentioned

Parameters

Method selects type of transform. It is one of the following names:

averageImage	Computes an average image for a stack of images contained in 3D <i>imageMatrix</i> . The average image is stored in the wave <i>M_AveImage</i> and the standard deviation for each pixel is stored in the wave <i>M_StdvImage</i> in the current data folder. You can use this keyword together with the optional <i>/R</i> flag where a region of interest is defined by zero value points in a ROI wave. The operation sets to NaN the entries in <i>M_AveImage</i> and <i>M_StdvImage</i> that correspond to pixels outside the ROI. <i>imageMatrix</i> must have at least three layers.
backProjection	Reconstructs the source image from a projection slice and stores the result in the wave <i>M_BackProjection</i> . The projection slice should either be a wave produced by the

	<p>projectionSlice keyword of this operation or a wave that would be similarly scaled. The input must be a single or double precision real 2D wave. Row scaling must range symmetrically about zero. For example, if the reconstructed image is expected to have 256 rows then the row scaling of the input should be from -128 to 127. Similarly, the column scaling of the input should range between zero and π. An equivalent implementation as a user function is provided in the demo experiment. You can use this implementation as a starting point if you want to develop filtered back projection. See the projectionSlice keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.</p>
ccsubdivision	<p>Performs a Catmull-Clark recursive generation of B-spline surfaces. There are two valid inputs: triangular meshes or quad meshes.</p> <p>Quad meshes are assumed to be in the form of a 3D wave where the first plane contains the X-values, the second the Y-values and the third the Z-values.</p> <p>Triangle meshes are much more complicated to convert into face-edge-vertex arrays so they are less desirable. They are stored in a three column (triplet) wave where the first column corresponds to the X coordinate, the second to the Y coordinate and the third to the Z coordinate. Each triangle is described by three rows in the wave and common vertices have to be repeated so that each sequential three rows in the triplet wave correspond to a single triangle. You can also associate a scalar value with each vertex and it will be suitably interpolated as new vertices are computed and old ones are shifted. In this case the input source wave contains one more column in the case of a triplet wave or one more plane in the case of a quad wave. The scalar value is added everywhere as an additional dimension to the spatial part of any point calculation.</p> <p>You can specify the number of iterations using the /I flag. By default the operation executes a single iteration. The output is saved in a quad wave M_CCBSplines that consists of 4 columns. Each row corresponds to a Quad where the 3 planes contain the X, Y, and Z components. If you are using an optional scalar in the input, the scalar result is stored in the wave M_CCBSscalar.</p>
cmap2rgb	Converts an image and its associated colormap wave (specified using the /C flag) into an RGB image stored in a 3D wave M_RGBOut.
CMYK2RGB	Converts a CMYK image, stored as 4 layer unsigned byte wave, into a 3 layer, standard RGB image wave. The output wave is M_CMYK2RGB that is stored in the current data folder.
compress	Compresses the data in the <i>imageWave</i> using a nonlossy algorithm and stores it in the wave W_Compressed in the current data folder. The compressed wave includes all data associated with <i>imageWave</i> including its units and wavenote. Use the decompress keyword to recover the original wave. The operation supports all numeric data types.
convert2gray	Converts an arbitrary 2D wave into an 8-bit normalized 2D wave. The default output wave name is M_Image2Gray.
decompress	Decompresses a compressed wave. It saves a copy of the decompressed wave under the name W_DeCompressed in the current data folder.
extractSurface	Extracts values corresponding to a plane that intersects a 3D volume wave (<i>imageMatrix</i>). You must specify the extraction parameters using the /X flag. The volume is defined by the wave scaling of the 3D wave. The result, obtained by trilinear interpolation, is stored in the wave M_ExtractedSurface and is of the type NT_FP64. Points in the plane that lie outside the volume are set to NaN.
fft	Performs a Fast Hartley Transform subject to the /T flag. The source wave must be a 2D real matrix with a power of 2 number of rows and columns. Default output is saved in the double-precision wave M_Hartley in the current data folder. If you use the /O flag the result overwrites <i>imageMatrix</i> without changing the numeric type. If <i>imageMatrix</i> is single-precision float the conversion is straightforward. All other numeric types are scaled. Single- and double-byte types are scaled to the full dynamic range. 32 bit integers are scaled to the range of the equivalent 16 bit types (i.e., unsigned int is scaled to unsigned short range etc.). It does not support wave scaling or NaN entries.
fillImage	Fills a 2D target image wave with data from a 1D image wave (specified using /D). Both waves must be the same data type, and the number of data points in the target wave

	must match the number of points in the data wave. There are four fill modes that are specified via the /M flag. The operation supports all noncomplex numeric data types.
findLakes	Originally intended to identify lakes in geographical data, this operation creates a mask for a 2D wave for all the contiguous points whose values are close to each other. You can determine the minimum number of pixels within a contiguous region using the /LARA flag (default is 100). You can determine how close values must be in order to belong to a contiguous region using the /LTOL= <i>tolerance</i> flag (default is zero). You can also limit the search region using the /LRCT flag. Use the flag /LTAR= <i>target</i> to set the value of the masked regions. By default, the algorithm uses 4-connectivity when looking at adjacent pixels. You can set it to 8-connectivity using the /LCVT flag. The result of the operation is saved in the wave M_LakeFill. It has the same data type as the source wave and contains all the source values outside the masked pixels.
flipCols	Rearrange pixels by exchanging columns symmetrically about a center column or the center of the image (if the number of columns is even). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.
flipRows	Rearrange pixels in the image by exchanging rows symmetrically about the middle row or the middle of the image (if the image has an even number of rows). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.
flipPlanes	Rearrange data in a 3D wave by exchanging planes symmetrically about the middle plane. The operation is performed in place and can be reverted by repeating the operation.
fuzzyClassify	<p>Segments grayscale and color images using fuzzy logic. Iteration stops when it reaches convergence defined by /TOL or the maximum number of iterations specified by /I. It is a good practice to specify the tolerance and the number of iterations. If the number of classes is small, the operation prints the class values in the history. Use /Q to eliminate printing and increase performance. Use /CLAS to specify the number of classes and optionally use /CLAM to modify the fuzzy probability values. Use /SEG to generate the segmentation image. The classes are stored in the wave W_FuzzyClasses in the current data folder and it will be overwritten if it already exists.</p> <p>When <i>imageMatrix</i> is a grayscale image, each class is a single wave entry. When <i>imageMatrix</i> is a RGB image, classes are stored consecutively in the wave W_FuzzyClasses. If you request more classes than are present in <i>imageMatrix</i>, you will likely find a degeneracy where the space of a data class is spanned by more than one class. It is a good idea to compute the Euclidean distance between every possible pair of classes and eliminate degeneracies when the distance falls below some threshold.</p> <p>Any real data type is allowed but values in the range [0,255] are optimal. You can segment 3D waves of more than 3 layers in which a class will be a vector of dimensionality equal to the number of layers in <i>imageMatrix</i>.</p> <p>For examples see Examples/Imaging/fuzzyClassifyDemo.pxp.</p>
getBeam	Extracts a beam from a 3D wave. A “beam” is a 1D array in the Z-direction (if a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension). The number of points in a beam is equal to the number of layers in <i>imageWave</i> . Specify the beam with the /Beam={ <i>row,column</i> } flag. It stores the result in the wave W_Beam in the current data folder. W_Beam has the same numeric type as <i>imageWave</i> . Use setBeam to set beam values. (See also, MatrixOP beam.)
getChunk	Extracts the chunk specified by chunk index /CHIX from <i>imageMatrix</i> and stores it in the wave M_Chunk in the current data folder. For example, if <i>imageMatrix</i> has the dimensions (10,20,3,10), the resulting M_Chunk has the dimensions (10,20,3). See also setChunk and insertChunk.
getCol	Extracts a 1D wave, named W_ExtractedCol, from any type of 2D or 3D wave. You specify the column using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. <i>imageMatrix</i> can be real or complex. (See also, MatrixOP col.)
getPlane	Creates a new wave, named M_ImagePlane, that contains data in the plane specified by the /P flag. The new wave is of the same data type as the source wave. You can specify the type of plane using the /PTYP flag. (See also, MatrixOP .)

getRow	Extracts a 1D wave, named W_ExtractedRow, from any type of 2D or 3D wave. You specify the row using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. <i>imageMatrix</i> can be real or complex. (See also, MatrixOP row.)
Hough	Performs the Hough transform on the input wave. The result is saved to a 2D wave M_Hough in which the rows are the angle domain and the columns are the radial domain. It is assumed that the input wave is binary with background value of 0. See Hough Transform on page III-299.
hsl2rgb	Transforms a 3-plane HSL wave into a 3-plane RGB wave. If the source wave for this operation is of any type other than byte or unsigned byte, the HSL values are expected to be between 0 and 65535. For all source wave types the resulting RGB wave is of type unsigned short. The result of the operation is the wave M_HSL2RGB (of type unsigned word), where the RGB values are in the range 0 to 65535.
hslSegment	Creates a binary image of the same dimensions as the source image, in which all pixels that belong to all three of the specified Hue, Saturation, and Lightness ranges are set to 255 and the others to zero. You can specify the HSL ranges using the /H, /S, and /L flags. Each flag takes as an argument either a pair of values or a wave containing pairs of values. You must specify the /H flag but you can omit the /S and /L flags in which case the default values (corresponding to full range 0 to 1) are used. <i>imageMatrix</i> is assumed to be an RGB image.
imageToTexture	Transforms a 2D or 3D image wave into a 1D wave of contiguous pixel components. The transformation is useful for creating an OpenGL texture (for Gizmo) or for saving a color image in a format requiring either RGB or RGBA sequences. Use the /TEXT flag to specify the type of transformation. <i>imageMatrix</i> must be an unsigned byte wave. It creates the 1D unsigned byte wave W_Texture in the current data folder.
insertChunk	Inserts a chunk (a 3D wave specified by the /D flag) into <i>imageMatrix</i> at chunk index specified by the /CHIX flag. The dimensions of the inserted chunk must match the first three dimensions of <i>imageMatrix</i> . The wave must also have the same numeric type. The 4th dimension of <i>imageMatrix</i> is incremented by 1 to accommodate the new data. See also getChunk and setChunk.
insertImage	Inserts the image specified by the flag /INSI into <i>imageMatrix</i> starting at the position specified by the flags /INSX and /INSY. If the <i>imageMatrix</i> is a 3D wave then it inserts the image in the layer specified by the /P flag. The inserted image and <i>imageMatrix</i> must be the same data type. The inserted data is clipped to the boundaries of <i>imageMatrix</i> .
insertXplane	Inserts a 2D wave as a new plane perpendicular to the X-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be cols x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 20x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.
insertYplane	Inserts a 2D wave as a new plane perpendicular to the Y-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.
insertZplane	Inserts a 2D wave as a new plane perpendicular to the Z-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x cols of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x20. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder. This keyword is included for completeness. You can accomplish the same task using InsertPoints.
Invert	Converts pixel values using the formula $newValue = 255 - oldValue$. Works on waves of any dimension, but only on waves of type unsigned byte. The result is stored in the wave M_Inverted unless specifying the /O flag.
indexWave	Creates a 1D wave W_IndexedValues in the current data folder containing values from <i>imageMatrix</i> that are pointed to by the index wave (see /IWAV). Each row in the index

	<p>wave corresponds to a single value of <i>imageMatrix</i>. If any row does not point to a valid index (within the dimensions of <i>imageMatrix</i>), the corresponding value is set to zero and the operation returns an error. Indices are zero based integers; the operation does not support interpolation and ignores wave scaling.</p>
JPEGQ	<p>Generates a lossy JPEG-compressed image wave when used together with the /J flag. The compressed image wave is stored in the wave M_JPEGQ and the size of the equivalent image file is stored in the variable V_value.</p>
matchPlanes	<p>Finds pixels that match test conditions in all layers of a 3D wave. It creates a 2D unsigned byte output wave, M_matchPlanes, that is set to the values 0 and 255. A value of 255 indicates that the corresponding pixel has satisfied test conditions in all layers of the wave for which conditions were provided. Otherwise the pixel value is 0.</p> <p>Test conditions are entered as a 2D wave using the /D flag. The condition wave must be double precision and it must contain the same number of columns as the number of layers in the 3D source wave. A condition for layer <i>j</i> of the source wave is specified by two rows in column <i>j</i> of the condition wave. The first row entry, say <i>A</i>, and the second row entry, say <i>B</i>, imply a condition on pixels in layer <i>j</i> such that $A \leq x < B$. You can have more than one condition for a given layer by adding pairs of rows to the condition wave. For example, if you add in consecutive rows the values <i>C</i> and <i>D</i>, this implies the test:</p> $(A \leq x < B) \parallel C \leq x < D.$ <p>If you do not have any conditions for some layer, set its corresponding condition column to NaN. Similarly, if you have two conditions for the first layer and one condition for the second layer, pad the bottom of column 1 in the condition wave with NaNs. See Examples for use of this keyword to perform hue/saturation segmentation.</p>
offsetImage	<p>Shifts an image in the XY plane by dx, dy pixels (specified by the /IOFF flag). Pixels outside the shifted image will be set to the specified background value. The operation works on 2D waves or on 3D waves with the optional /P flag. When shifting a 3D wave with no specified plane, it creates a 3D wave with all planes offset by the same amount. The wave M_OffsetImage contains the result in the current data folder.</p>
padImage	<p>Resizes the source image. When enlarged, values from the last row and column fill in the new area. The /N flag specifies the new image size in terms of the rows and columns change. The /W flag specifies whether data should be wrapped when padding the image. Unless you use the /O flag, the result is stored in the wave M_PaddedImage in the current data folder.</p>
projectionSlice	<p>Computes a projection slice for a parallel fan of rays going through the image at various angles. For every ray in the fan the operation computes a line integral through the image (equivalent to the sum of the line profile along the ray). The operation computes the line integrals for multiple fans defined by the number and position of the rays as well as the angle that they make with the positive X-direction. Use the /PSL flag to specify the projection parameters. The projection slice itself is stored in a 2D wave M_ProjectionSlice where the rows correspond to the rays and the columns correspond to the selected range of angles. The operation does not support wave scaling. If the source wave is 3D the projection slice currently supports slices that are perpendicular to the z-axis and specified by their plane number.</p> <p>See the backProjection keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.</p>
putCol	<p>Sets a column of <i>imageMatrix</i> to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number.</p>
putRow	<p>Sets a row of <i>imageMatrix</i> to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number.</p>
rgb2cmap	<p>Computes a default color map of 256 colors to represent the input RGB image. The colors are computed by clustering the input pixels in RGB space. The resulting color map is stored in the wave M_ColorIndex in the current data folder. The operation also</p>

	<p>saves the wave <code>M_IndexImage</code> which contains an index into the colormap that can be used to display the image using the commands:</p> <pre>NewImage M_IndexImage ModifyImage M_IndexImage cindex= M_ColorIndex</pre> <p>To change the default number of colors use the <code>/NCLR</code> flag. When the number of colors are greater than 256, <code>M_IndexImage</code> will be a 16-bit unsigned integer or a 32 bit integer wave depending on the number. <code>rgb2cmap</code> supports input images in the form of 3D waves of type unsigned byte or single precision float. The floating point option may be used to input images in colorspace that use signed numeric data.</p>
<code>rgb2gray</code>	<p>Converts an RGB image stored in a 3D wave into a 2D wave of type unsigned char with the name <code>M_RGB2Gray</code>. The RGB values are converted into the luminance Y of the YIQ standard using $Y=0.299R+0.587G+0.114B$.</p>
<code>rgb2hsl</code>	<p>Converts an RGB image stored in a 3D wave into another 3D wave in which the three planes correspond to Hue, Saturation and Lightness in the HSL color model. Values of all components are normalized to the range 0 to 255 unless the <code>/U</code> flag is used or if the source wave is not 8-bit, in which case the range is 0 to 65535. The default output wave name is <code>M_RGB2HSL</code>.</p>
<code>rgb2i123</code>	<p>Performs a colorspace conversion of an RGB image into the following quantities:</p> $I1 = R - G \cdot D$ $I2 = R - B \cdot D, \text{ where } D = \frac{255}{ R - G + R - B + G - B }$ $I3 = G - B \cdot D$ <p>$I1$, $I2$, and $I3$ are stored in the wave <code>M_I123</code> (using the same data type as the original RGB wave) in the current data folder. $I1$ is stored in the first layer, $I2$ in the second and $I3$ in the third. This color transformation is said to have useful applications in machine vision. For more information see: Gevers and Smeulders (1999).</p>
<code>removeXplane</code>	<p>Removes one or more planes perpendicular to the X-axis from a 3D wave. The <code>/P</code> flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the <code>/NP</code> flag. If you do not use the <code>/O</code> flag, it saves the result in the wave <code>M_ReducedWave</code> in the current data folder.</p>
<code>removeYplane</code>	<p>Removes one or more planes perpendicular to the Y-axis from a 3D wave. The <code>/P</code> flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the <code>/NP</code> flag. If you do not use the <code>/O</code> flag, it saves the result in the wave <code>M_ReducedWave</code> in the current data folder.</p>
<code>removeZplane</code>	<p>Removes one or more planes perpendicular to the Z-axis from a 3D wave. The <code>/P</code> flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the <code>/NP</code> flag. If you do not use the <code>/O</code> flag, it saves the result in the wave <code>M_ReducedWave</code> in the current data folder.</p>
<code>rgb2xyz</code>	<p>converts a 3D RGB image wave into a 3D wave containing the XYZ color space equivalent. The conversion is based on the D65 white point and uses the following transformation:</p> $\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0.412453 & 0.357580 & 0.189423 \\ 0.212671 & 0.715160 & 0.072169 \\ 0.019334 & 0.119193 & 0.950227 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}$ <p>The XYZ values are stored in a wave named "<code>M_RGB2XYZ</code>" unless the <code>/O</code> flag is used, in which case the source image is overwritten and converted into single precision wave (NT_FP32).</p>
<code>roiTo1D</code>	<p>Copies all pixels in an ROI and saves them sequentially in a 1D wave. The ROI is specified by <code>/R</code>. The ROI wave must have the same dimensions as <i>imageMatrix</i>. If <i>imageMatrix</i> is a 3D wave, the ROI must have as many layers as <i>imageMatrix</i>. The wave <code>W_roi_to_1d</code> contains the output in the current data folder, has the same numeric type as <i>imageMatrix</i>, and contains the selected pixels in a column-major order.</p>
<code>rotateRows</code>	<p>Rotates rows in place. This operation is analogous to the Rotate operation except that it works on images and rotates an integer number of rows. The number of rows is specified by the <code>/G</code> flag.</p>

rotateCols	<p>Rotates columns in place. This operation is analogous to the Rotate operation except that it works on images and rotates an integer number of columns. The number of columns is specified by the /G flag.</p>
scalePlanes	<p>Scales each plane of the 3D wave, <i>imageMatrix</i>, by a constant taken from the corresponding entry in the 1D wave specified by the /D flag. The result is stored in the wave M_ScaledPlanes unless the /O flag is specified, in which case scaling is done in place.</p> <p>When using /O, first redimension the wave to a different data type to make sure there are no artifacts due to type clipping.</p> <p>If <i>imageMatrix</i> is double precision, M_ScaledPlanes is double precision. Otherwise M_ScaledPlanes is single precision.</p> <p>This operation also supports the optional flag.</p> <p>Note that when you display M_ScaledPlanes, which has three planes that originated from scaling byte data, you will have to multiply the wave by 255 to see the image because the RGB format for single and double precision data requires values in the range 0 to 65535.</p>
selectColor	<p>Creates a mask for the image in which pixel values depend on the proximity of the color of the image to a given central color. The central color, the tolerance and a grayscale indicator must be specified using the /E flag.</p> <p>For example, /E={174,187,75,10,1} specifies an RGB of (174,187,75), a tolerance level of 10 and a requested grayscale output.</p> <p>RGB values must be provided in a range appropriate for the source image. If the source wave type is not byte or unsigned byte, then the range of the RGB components should be 0 to 65535.</p> <p>The color proximity is calculated in the nonuniform RGB space and the tolerance applies to the maximum component difference from the corresponding component of the central color.</p> <p>The tolerance, just like the central color, should be appropriate to the type of the source wave.</p> <p>The generated mask is stored in the wave M_SelectColor in the current data folder. If a wave by that name exists prior to the execution of this operation, it is overwritten. You can also use the /R flag with this operation to limit the color selection to pixels in the ROI wave whose value is zero.</p>
setBeam	<p>Sets the data of a particular beam in <i>imageMatrix</i>. A “beam” is a 1D array in the Z-direction (if a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension). Specify the beam with the /Beam={row,column} flag and the 1D beam data wave with the /D flag. The beam data wave must have the same number of elements as the number of layers and same numeric type as <i>imageMatrix</i>. Use getBeam to extract the beam.</p>
setChunk	<p>Overwrites the data in the wave <i>imageMatrix</i> at chunk index specified by /CHIX with the data contained in a 3D wave specified by the /D flag. The assigned data must be contained in a wave that matches the first three dimensions of <i>imageMatrix</i> and must have the same number type. See also getChunk and insertChunk.</p>
setPlane	<p>Sets a plane (given by the /P flag) in the designated image with the data in a wave specified by the /D flag. It is designed as a complement of the getPlane keyword to provide an easier (faster) way to create multiplane images. Note that the operation supports setting a plane when the source data is smaller than the destination plane in which case the source data is placed in memory contiguously starting from the corner pixel of the destination plane. If the source data is larger than the destination plane it is clipped to the appropriate rows and columns. If you are setting all planes in the destination wave using algorithmically named source waves you could use the stackImages keyword instead.</p>
shading	<p>Calculates relative reflectance of a surface for a light source position defined by the /A flag.</p> <p>The operation estimates the slope of the surface and then computes a relative reflectance defined as the dot product of the direction of the light and the normal to the surface at the point of interest. Reflectivity is scaled using the expression:</p> $outPixel = shadingA * (sunDirection \cdot surfaceNormal) + shadingB$

	<p>By default <i>shadingA</i>=1, <i>shadingB</i>=0.</p> <p>The result is stored in the wave M_ShadedImage, which has the same data type as the source wave.</p> <p>If the source wave is any integer type, and the value of <i>shadingA</i>=1 the operation sets that value to 255.</p> <p>The smallest supported wave size is 4x4 elements.</p> <p>Values along the boundary (1 pixel wide) are arbitrary because there are no derivatives calculable for those pixels, so these pixels are filled with duplicates of the inner rows and columns.</p>
shrinkRect	Shrinks <i>imageMatrix</i> to include only the minimum rectangle that contains all the pixels whose value is different from an outer value. The outer value is specified with the /F flag. This is useful in situations where ImageSeedFill has set the pixels around the object of interest to some outer value and it is desired to extract the smallest rectangle that contains interesting data. The output is stored in the wave M_Shrunk.
stackImages	<p>Creates a 3D or 4D stack from individual image waves in the current data folder. The waves should be of the form <i>baseNameN</i>, where <i>N</i> is a numeric suffix specifying the sequence order. <i>imageMatrix</i> should be the name of the first wave that you want to add to the stack. You can use the /NP flag to specify the number of waves that you want to add to the stack</p> <p>The result is a 3D or 4D wave named M_Stack, which overwrites any existing wave of that name in the current data folder.</p> <p>With /K, it kills all waves copied into the stack.</p>
sumAllCols	Creates a wave W_sumCols in which every entry is the sum of the pixels on the corresponding image column. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.
sumAllRows	Creates a wave W_sumRows in which every entry is the sum of the pixels on the corresponding image row. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.
sumCol	Stores in the variable V_value the sum of the elements in the column specified by /G flag and optionally the /P flag.
sumPlane	Stores in the variable V_value the sum of the elements in the plane specified by the /P flag.
sumPlanes	Creates a 2D wave M_SumPlanes which contains the same number of rows and columns as the 3D source wave. Each entry in M_SumPlanes is the sum of the corresponding pixels in all the planes of the source wave. M_SumPlanes is a double precision wave if the source wave is double precision. Otherwise it is a single precision wave.
sumRow	Stores in the variable V_value the sum of the elements of a row specified by /G flag and optionally the /P flag.
swap	Swaps image data following a 2D FFT. The transform swaps diagonal quadrants of the image in one or more planes. This keyword does not support any flags. The swapping is done in place and it overwrites the source wave.
swap3D	Swaps data following a 3D FFT. The transform swaps diagonal quadrants of the data. This keyword does not support any flags. The swapping is done in place and the source wave is overwritten.
transposeVol	Transposes a 3D wave. The transposed wave is stored in M_VolumeTranspose. The /O flag does not apply. The operation supports the following 5 transpose modes which are specified using the /G flag:

<i>mode</i>	Equivalent Command
1	M_VolumeTranspose= <i>imageMatrix</i> [p][r][q]
2	M_VolumeTranspose= <i>imageMatrix</i> [r][p][q]
3	M_VolumeTranspose= <i>imageMatrix</i> [r][q][p]
4	M_VolumeTranspose= <i>imageMatrix</i> [q][r][p]
5	M_VolumeTranspose= <i>imageMatrix</i> [q][p][r]

vol2surf	Creates a quad-wave output (appropriate for display in Gizmo) that wraps around 3D “particles”. A particle is defined as a region of nonzero value voxels in a 3D wave. The algorithm effectively computes a box at the resolution of the input wave which completely encloses the data. The output wave M_Boxy is a 2D single precision wave of 12 columns where each row corresponds to one disjoint quad and the columns provide the sequential X, Y, and Z coordinates of the quad vertices.
voronoi	Computes the voronoi tessellation of a convex domain defined by the X, Y positions of the input wave. <i>imageMatrix</i> must be a triplet wave where the first column contains the X-values, the second column contains the Y-values and the third column is an arbitrary (zero is recommended) constant. The result of the operation is stored in the two column wave M_VoronoiEdges which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle which contains the convex domain.
xProjection	Computes the projection in the X-direction and stores the result in the wave M_xProjection. See zProjection for more information.
xyz2rgb	<p>Converts a 3D single precision XYZ color-space data into RGB based on the D65 white point. The transformation used is:</p> $\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} 3.240479 & -1.537150 & -0.498535 \\ -0.969256 & 1.875992 & 0.041556 \\ 0.055648 & -0.204043 & 1.057311 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}.$ <p>If you do not specify the /O flag, the results are saved in a single precision 3D wave (NT_FP32) “M_XYZ2RGB”.</p> <p>Note that not all XYZ values map into positive RGB triplets (consider colors that reside outside the RGB triangle in the XYZ diagram). This operation gives you the following choices: by default, the output wave is a single precision wave that will include possible negative RGB values. If you specify the /U flag, for unsigned short output wave, the operation will set to zero all negative components and scale the remaining ones in the range 0 to 65535.</p>
yProjection	Computes the projection in the Y-direction and stores the result in the wave M_yProjection. See zProjection for more information.
zDot	Computes the dot product of a beam in <i>srcWave</i> with a 1D zVector wave (specified with the /D flag). This will convert stacked images of spectral scans into RGB or XYZ depending on the scaling in zVector. The <i>srcWave</i> and zVector must be the same data type (float or double). The wave M_StackDot contains the result in the current data folder.
zProjection	Computes the projection in the Z-direction and stores the result in the wave M_zProjection. The source wave must be a 3D wave of arbitrary data type. The value of the projection depends on the method specified via the /METH flag.

Flags

/A={azimuth, elevation [, shadingA, shadingB]}	<p>Specifies parameters for shade. Position of the light source is given by <i>azimuth</i> (measured in degrees counter-clockwise) and <i>elevation</i> (measured in degrees above the horizon).</p> <p>The parameters <i>shadingA</i> and <i>shadingB</i> are optional. By default their values are 1 and 0, respectively.</p>
/Beam={row,column}	Designates a beam in a 3D wave; both <i>row</i> and <i>column</i> are zero based.
/BPJ={width,height}	Specifies the backProjection parameters: <i>width</i> and <i>height</i> are the width and height of the reconstructed image and should be equal to the size of the original wave.
/C=CMapWave	Specifies the colormap wave for cmap2rgb keyword. The <i>CMapWave</i> is expected to be a 2D wave consisting of three columns corresponding to the RGB entries.
/CHIX=chunkIndex	Identifies the chunk index for getting, inserting or setting a chunk of data in a 4D wave. <i>chunkIndex</i> ranges from 0 to the number of chunks in <i>imageMatrix</i> .
/CLAM=fuzzy	Sets the value used to compute the fuzzy probability in fuzzyClassify. It must satisfy <i>fuzzy</i> > 1 (default is 2).

/CLAS= <i>num</i>	Sets the number of requested classes in fuzzyClassify. If you don't know the number of expected classes and <i>num</i> is too high, fuzzyClassify will likely produce some degenerate classes.
/D= <i>waveName</i>	Specifies a data wave. Check the appropriate keyword documentation for more information about this wave.
/F= <i>value</i>	Increases the sampling in the angle domain when used with the Hough keyword. By default <i>value</i> =1 and the operation results in single degree increments in the interval 0 to 180, and if <i>value</i> =1.5 there will be 180*1.5 rows in the transform. Specifies the outer pixel value surrounding the region of interest when used with shrinkRect keyword.
/G= <i>colNumber</i>	Specifies either the row or column number used in connection with getRow or getCol keywords. This flag also specifies the transpose <i>mode</i> with the transposeVol keyword.
/H={ <i>minHue, maxHue</i> }	Specifies the range of hue values for selecting pixels. The hue values are specified in degrees in the range 0 to 360. Hue intervals that contain the zero point should be specified with the higher value first, e.g., /H={330, 10}. Use <i>hueWave</i> when you have more than one pair of hue values that bracket the pixels that you want to select. See HSL Segmentation on page III-309 for an example.
/H= <i>hueWave</i>	
/I= <i>iterations</i>	Sets the number of iterations in ccsubdivision and in fuzzyClassify.
/INSI= <i>imageWave</i>	Specifies the wave, <i>imageWave</i> , to be used with the insertImage keyword. <i>imageWave</i> is a 2D wave of the same numeric data type as <i>imageMatrix</i> .
/INSW= <i>wave</i>	Specifies the 2D wave to be inserted into a 3D wave using the keywords: insertXplane, insertYplane, or insertZplane.
/INSX= <i>xPos</i>	Specifies the pixel position at which the first row is inserted. Ignores wave scaling.
/INSY= <i>yPos</i>	Specifies the pixel position at which the first column is inserted. Ignores wave scaling.
/IOFF={ <i>dx,dy,bgValue</i> }	Specifies the amount of positive or negative integer offset with <i>dx</i> and <i>dy</i> and the new background value, <i>bgValue</i> , with the offsetImage keyword.
/IWAV= <i>wave</i>	Specifies the wave which provides the indices when used with the keyword indexWave. The wave should have as many columns as the dimensions of <i>imageMatrix</i> (2, 3, or 4). For example, to specify indices for pixels in an image, the wave should have two columns. The first column corresponds to the row designation and the second to the column designation of the pixel. The wave can be of any number type (other than complex) and entries are assumed to be integer indices; there is no support for interpolation or for wave scaling.
/J= <i>quality</i>	Specifies the quality of JPEG image compression. <i>quality</i> can have values ranging from 0 (lowest) to 100 (highest). This flag is used with the JPEGQ keyword.
/L={ <i>minLight, maxLight</i> }	Specifies the range of lightness for selecting pixels. The lightness values are in the range 0-1. If you do not use the /L flag than the default full range is used. Use <i>lightnessWave</i> when you have more than one pair of lightness values corresponding to the pixels that you want to select. For each pair, values should be arranged so that the smaller one is first and the larger is second. There is no restriction on the order of pairs in the wave except that they match the other waves used by the operation.
/L= <i>lightnessWave</i>	
/LARA= <i>minPixels</i>	Specifies the minimum number of pixels required for an area to be masked by the findLakes keyword. If you do not specify this flag, the default value used is 100.
/LCVT	use 8-connectivity instead of 4-connectivity.
/LRCT={ <i>minX,minY,maxX,maxY</i> }	Sets the rectangular region of interest for the findLakes keyword. The operation will not affect the original data outside the specified rectangle. The X and Y values are the scaled values (i.e., using wave scaling).
/LTAR= <i>target</i>	Set the target value for the masked region in the findLakes keyword.

/LTOL= <i>tol</i>	Specifies the tolerance for the findLakes keyword. By default the tolerance is zero. The tolerance must be a positive number. The operation uses the tolerance by requiring neighboring pixels to have a value between that of the current pixel <i>V</i> and <i>V+tol</i> .
/M= <i>n</i>	Specifies the method by which a 2D target image is filled with data from a 1D wave using the fillImage keyword. <i>n</i> =0: Straight column fill, which you can also accomplish by a redimension operation. <i>n</i> =1: Straight row fill. <i>n</i> =2: Serpentine column fill. The points from the data wave are sequentially loaded onto the first column and continue from the last to the first point of the second column, and then sequentially through the third column, etc. <i>n</i> =3: Serpentine row fill.
/METH= <i>method</i>	Determines the values of the projected pixels for xProjection, yProjection, and zProjection keywords. <i>method</i> =1: Pixel (i,j) in M_zProjection is assigned the maximum value that (i,j,*) takes among all layers of <i>imageMatrix</i> (default). <i>method</i> =2: Pixel (i,j) in M_zProjection is assigned the average value that (i,j,*) takes among all layers of <i>imageMatrix</i> . <i>method</i> =3: Pixel (i,j) in M_zProjection is assigned the minimum value that (i,j,*) takes among all layers of <i>imageMatrix</i> .
/N={ <i>rowsToAdd</i> , <i>colsToAdd</i> }	Creates an image that is larger or smaller by <i>rowsToAdd</i> , <i>colsToAdd</i> . The additional pixels are set by duplicating the values in the last row and the last column of the source image.
/NCLR= <i>M</i>	Specifies the maximum number of colors to find with the rgb2cmap keyword. <i>M</i> must be a positive number; the default value is 256 colors. The result of the operation is saved in the wave M_paddedImage.
/NP= <i>numPlanes</i>	Specifies the number of planes to remove from a 3D wave when using the removeXplane, removeYplane, or removeZplane keywords. Specifies the number of waves to be added to the stack with the stackImages keyword.
/O	Overwrites the input wave with the result except in the cases of Hough transform and cmap2rgb. Does not apply to the transposeVol parameter.
/P= <i>planeNum</i>	Specifies the plane on which you want to operate with the rgb2gray or getPlane keywords. Also used for getRow or getCol if the source wave is 3D.
/PSL={ <i>xStart</i> , <i>dx</i> , <i>Nx</i> , <i>aStart</i> , <i>da</i> , <i>Na</i> }	Specifies projection slice parameters. <i>xStart</i> is the first offset of the parallel rays measured from the center of the image. <i>dx</i> is the directed offset to the next ray in the fan and <i>Nx</i> is the number of rays in the fan. <i>aStart</i> is the first angle for which the projection is calculated. The angle is measured between the positive X-direction and the direction of the ray. <i>da</i> is the offset to the next angle at which the fan of rays is rotated and <i>Na</i> is the total number of angles for which the projection is computed.
/PTYP= <i>num</i>	Specifies the plane to use with the getPlane keyword. <i>num</i> =0: XY plane. <i>num</i> =1: XZ plane. <i>num</i> =2: YZ plane.
/Q	Quiet flag. When used with the Hough transform, it suppresses report to the history of the angle corresponding to the maximum.
/R= <i>roiWave</i>	Specifies a region of interest (ROI) defined by <i>roiWave</i> . For use with the keywords: averageImage, scalePlanes and selectColor.
/S={ <i>minSat</i> , <i>maxSat</i> }	
/S= <i>saturationWave</i>	Specifies the range of saturation values for selecting pixels. The saturation values are in the range 0 to 1. If you do not use the /S flag, the default value is the full saturation range. Use <i>saturationWave</i> when you have more than one pair of saturation values. If you use a saturation wave you must also use a lightness wave (see /L). <i>saturationWave</i> should consist

	of pairs of values where the first point is the lower saturation value and the second point is the higher saturation value. There is no restriction on the order of pairs within the wave.
/SEG	Computes the segmentation image for fuzzyClassify. The image is stored in the 2D wave M_FuzzySegments. The value of each pixel is $255 \cdot \text{classIndex} / \text{number of classes}$. Here <i>classIndex</i> is the index of the class to which the pixel belongs with the highest probability.
/T=flag	Use one or more of the following flags. 1: Swaps the data so that the DC is at the center of the image. 2: Calculates the power defined as: $P(f) = 0.5 \cdot (H(f)^2 + H(-f)^2)$.
/TEXT=val	Specifies the type of texture to create with the imageToTexture keyword. <i>val</i> is a binary flag that can be a combination of the following values.
<i>val</i>	Texture
1	Truncates each dimension to the nearest power of 2, which is required for OpenGL textures.
2	Creates a 1D texture (all other textures are for 2D applications).
4	Creates a single channel texture suitable for alpha or luminance channels.
8	Creates a RGB texture from a 3 (or more) layer data.
16	Creates a RGBA texture. If <i>imageMatrix</i> does not have a 4th layer, alpha is set to 255.
/TOL=tolerance	Sets the tolerance for iteration convergence with fuzzyClassify. Convergence is satisfied when the sum of the squared differences of all classes drops below <i>tolerance</i> , which must not be negative.
/U	Creates an HSL wave of type unsigned short that contains values between 0 and 65535 when used with rgb2hsl.
/W	Pads the image by wrapping the data. If you are adding more rows or more columns than are available in the source wave, the operation cycles through the source data as many times as necessary.
/X={Nx,Ny,x1,y1,z1,x2,y2,z2,x3,y3,z3}	<i>Nx</i> and <i>Ny</i> are the rows and columns of the wave M_ExtractedSurface. The remaining parameters specify three 3D points on the extracted plane. The three points must be chosen at the vertices of the plane and entered in clock-wise order without skipping a vertex.
/Z	Ignores errors.

Examples

If you want to insert a 2D (M x N) wave, plane0, into plane number 0 of an (M x N x 3) wave, rgbWave:

```
ImageTransform /P=0/D=plane0 setPlane rgbWave
```

If your source wave is 100 rows by 100 columns and you want to create a montage of this image use:

```
ImageTransform /W/N={200,200} padImage srcWaveName
```

An example of hue and saturation segmentation on an HSL wave.

```
Function hueSatSegment(hslW,lowH,highH,lowS,highS)
  Wave hslW
  Variable lowH,highH,lowS,highS
  Make/D/O/N=(2,3) conditionW

ImageUnwrapPhase

ImageUnwrapPhase [*flags*] [**qualityWave**=*qWave*,] **srcwave**=*waveName*

The ImageUnwrapPhase operation unwraps the 2D phase in srcWave and stores the result in the wave M_UnwrappedPhase in the current data folder. srcWave must be a real valued wave of single or double precision. Phase is measured in cycles (units of 2π).

Parameters

- qualityWave**=*qWave* Specifies a wave, *qWave*, containing numbers that rate the quality of the phase stored in the pixels. *qWave* is 2D wave of the same dimensions as srcWave that can be any real data type and values can have an arbitrary scale. If used with /M=1 the quality values determine the order of phase unwrapping subject to branch cuts, with higher quality unwrapped first. If used with /M=2 the unwrapping is guided by the quality values only. This wave must not contain any NaNs or INFs.
- srcwave**=*waveName* Specifies a real-valued SP or DP wave that may contain NaNs or INFs but is otherwise assumed to contain the phase modulo 1.

Flags

- /E Eliminate dipoles. Only applies to Goldstein's method (/M=1). Dipoles are a pair of a positive and negative residues that are side by side. They are eliminated from the unwrapping process by replacing them with a branch cut. The variable V_numResidues contains the number of residues remaining after removal of the dipoles.
- /L Saves the lookup table(LUT) used in the analysis with /M=1. This information may be useful in analyzing your results. The LUT is saved as a 2D unsigned byte wave M_PhaseLUT in the current data folder. Each entry consists of 8-bit fields:
- bit 0: Positive residue.
 - bit 1: Negative residue.
 - bit 2: Branch cut.
 - bit 3: Image boundary exclusion.
- Other bits are reserved and subject to change. See **Setting Bit Parameters** on page IV-11 for details about bit settings.
- /M=*method* Determines the method for computing the unwrapped phase:
- method*=0: Modified Itoh's algorithm, which assumes that there are no residues in the phase. The phase is unwrapped in a contiguous way subject only to the ROI or singularities in the data (e.g., NaNs or INFs). You will get wrong results for the unwrapped phase if you use this method and your data contains residues.
 - method*=1: Modified Goldstein's algorithm. Creates the variables V_numResidues and V_numRegions. Optional *qWave* can determine order of unwrapping around the branch cuts.
 - method*=2: Uses a quality map to decide the unwrapping path priority. The quality map is a 2D wave that has the same dimensions as the source wave but could have an arbitrary data type. The phase is unwrapped starting from the largest value in the quality map.
- /MAX=*len* Specifies the maximum length of a branch cut. Only applicable to Goldstein's method (/M=1). By default this is set to the largest of rows or columns.
- /Q Suppresses messages to the history.

- `/R=roiWave` Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (`/b/u`) that has the same number of rows and columns as *waveName*. The ROI itself is defined by entries or pixels in the *roiWave* with value of 1. Pixels outside the ROI should be set to zero. The ROI does not have to be contiguous but it is best if you choose a convex ROI in order to make sure that any branch cuts computed by the algorithm lie completely inside the ROI domain.
- `/REST = threshold` Sets the threshold value for evaluating a residue. The residue is evaluated by the equivalent of a closed path integral. If the path integral value exceeds the threshold value, the top-left corner of the quad is taken to be a positive residue. If the path integral is less than *-threshold*, it is a negative residue.

Details

Phase unwrapping in two dimensions is difficult because the result of the operation needs to be such that any path integral over a closed contour will vanish. In many practical situations, certain points in the plane have the property that a path integral around them is not zero. These nonzero points are residues. We use the definition that when a counterclockwise path integral leads to a positive value the residue is called a positive residue.

ImageUnwrapPhase uses the modified Itoh's method by default. Phase is unwrapped with an offset equal to the first element that is allowed by the ROI starting at (0,0) and scanning by rows. If there are no residues or if you unwrap the phase using Itoh's algorithm, then the phase is unwrapped only subject to the optional ROI using a seed-fill type algorithm that unwraps by growing a region outward from the seed pixel. Each time that the region growing is terminated by boundaries (external or due to the ROI), the algorithm returns to the row scanning to find a new starting point.

If there are residues and you choose Goldstein's method, the residues are first mapped into a lookup table (LUT) and branch-cuts are determined between residues and boundaries. It is also possible to remove some residues (dipoles) using the `/E` flag. Phase is then unwrapped in regions bounded by branch cuts using a seed-fill type algorithm that does not cross branch cuts. With a quality wave, the algorithm follows the same seed-fill approach except that it gives priority to pixels with high quality level. The phase on the branch cuts themselves is subsequently calculated.

The output wave `M_UnwrappedPhase` has the same wave scaling and dimension units as `srcWave`. The unwrapped phase is units of cycles; you will have to multiply it by 2π if you need the results in radians.

The operation creates two variables:

- `V_numResidues` Number of residues encountered(if using `/M=1`).
- `V_numRegions` Number of independent phase regions. In Goldstein's method the regions are bounded by branch cuts, but in Itoh's method they depend on the content of the ROI wave.

Examples

To unwrap a complex wave `wCmplx`:

```
Make/O/N=(DimSize(wCmplx,0),DimSize(wCmplx,1)) phaseWave
phaseWave=atan2(imag(wCmplx),real(wCmplx))/2*pi
ImageUnwrapPhase/N=1 srcWave=phaseWave
```

To find the locations of positive residues in the phase:

```
ImageUnwrapPhase/N=1/L srcWave=phaseWave
Duplicate/O M_PhaseLUT ee
ee=M_PhaseLUT&3 ? 1:0
```

To find the branch cuts:

```
Duplicate/O M_PhaseLUT bc
bc=M_PhaseLUT&4 ? 1:0
```

References

The following reference is an excellent text containing in-depth theory and detailed explanation of many two-dimensional phase unwrapping algorithms:

Ghiglia, Dennis C., and Mark D. Pritt, *Two Dimensional Phase Unwrapping — Theory, Algorithms and Software*, Wiley, 1998.

ImageWindow

ImageWindow [/I/O/P=*param*] **method** *srcWave*

The ImageWindow operation multiplies the named waves by the specified windowing method.

ImageWindow is useful in preparing an image for FFT analysis by reducing FFT artifacts produced at the image boundaries.

Parameters

srcWave Two-dimensional wave of any numerical type. See **WindowFunction** for windowing one-dimensional data.

method Selects the type of windowing filter, which is one of the following:

Hanning: $w(n) = \frac{1}{2} \left[1 - \cos\left(\frac{2\pi n}{L-1}\right) \right] \quad 0 \leq n \leq L-1.$

Hamming: $w(n) = 0.54 - 0.46 \cos\left(\frac{2\pi n}{L-1}\right) \quad 0 \leq n \leq L-1.$

Bartlett: Synonym for Bartlett.

Bartlett: $w(n) = \begin{cases} \frac{2n}{L-1} & 0 \leq n \leq \frac{L-1}{2} \\ 2 - \frac{2n}{L-1} & \frac{L-1}{2} \leq n \leq L-1 \end{cases}.$

Blackman: $w(n) = 0.42 - 0.5 \cos\left(\frac{2\pi n}{L-1}\right) + 0.08 \cos\left(\frac{4\pi n}{L-1}\right) \quad 0 \leq n \leq L-1.$

Kaiser:
$$\frac{I_0 \left\{ \omega_a \left[((L-1) \lfloor \frac{n}{L} \rfloor)^2 - [n - ((L-1) \lfloor \frac{n}{L} \rfloor)]^2 \right] \right\}}{I_0 \{ \omega_a ((L-1) \lfloor \frac{n}{L} \rfloor) \}} \quad 0 \leq n \leq L-1.$$

where $I_0\{\dots\}$ is the zeroth-order Bessel function of the first kind and ω_a is the design parameter specified by /P=*param*.

KaiserBessel20: $\alpha = 2.$

KaiserBessel25: $\alpha = 2.5.$

KaiserBessel30: $\alpha = 3.$

$$w(n) = \frac{I_0 \left(\pi \alpha \sqrt{1 - \left(\frac{n}{(L) \lfloor \frac{n}{L} \rfloor} \right)^2} \right)}{I_0(\pi \alpha)} \quad 0 \leq |n| \leq \frac{L}{2}.$$

$$I_0(X) = \sum_{k=0}^{\infty} \left(\frac{(x \lfloor \frac{n}{L} \rfloor)^2}{k!} \right)^2$$

In all equations, L is the array width and n is the pixel number.

Flags

/I Creates only the output wave containing the windowing filter values that are used to multiply each pixel in *srcWave*. It does not filter the source image.

/O Overwrites the source image with the output image. If /O is not used then the operation creates the M_WindowedImage wave containing the filtered source image.

/P=*param* Specifies the design parameter for the Kaiser window.

Details

The 1-dimensional window for each column is multiplied by the value of the corresponding row's window value. In other words, each point is multiplied by the both the row-oriented and column-oriented window value.

This means that all four edges of the image are decreased while the center remains at or near its original value. For example, applying the Bartlett window to an image whose values are all equal results in a trapezoidal pyramid of values:

The default output wave is created with the same data type as the source image. Therefore, if the source image is of type unsigned byte (/b/u) the result of using /I will be identically zero (except possibly for the middle-most pixel). If you keep in mind that you need to convert the source image to a wave type of single or double precision in order to perform the FFT, it is best if you convert your source image (e.g., `Redimension/S srcImage`) before using the ImageWindow operation.

The windowed output is in the M_WindowedImage wave unless the source is overwritten using the /O flag. The necessary normalization value (equals to the average squared window factor) is stored in V_value.

Examples

To see what one of the windowing filters looks like:

```
Make/N=(80,80) wShape // Make a matrix
ImageWindow/I/O Blackman wShape // Replace with windowing filter
Display;AppendImage wShape // Display windowing filter
Make/N=2 xTrace={0,79},yTrace={39,39} // Prepare for 1D section
AppendToGraph yTrace vs xTrace
ImageLineProfile srcWave=wShape, xWave=xTrace, yWave=yTrace
Display W_ImageLineProfile // Display 1D section of filter
```

IndependentModule

#pragma IndependentModule = imName

The IndependentModule pragma designates groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

The ModuleName pragma will not work with versions of Igor Pro older than 6.0.

See Also

The **The IndependentModule Pragma** on page IV-40 and **#pragma**.

IndexedDir

IndexedDir(pathName, index, flags)

The IndexedDir function returns a string containing the name of or the full path to the *index*th folder in the folder referenced by *pathName*.

Parameters

pathName is the name of an Igor symbolic path pointing to the parent directory.

index is the index number of the directory (within the parent directory) of interest starting from 0. If *index* is -1, IndexedDir will return the name of *all* of the folders in the parent, separated by semicolons.

flags is a bitwise parameter:

- Bit 0: Set if you want a full path. Cleared if you want just the directory name.
- All other bits are reserved and should be cleared.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Details

You create the symbolic path identifying the parent directory using the **NewPath** operation or the New Path dialog (Misc menu).

Prior to Igor Pro 3.1, IndexedDir was an external function and took a string as the first parameter rather than a name. The *pathName* parameter can now be either a name or a string containing a name. Any of the following will work:

```
String str = "IGOR"
Print IndexedDir(IGOR, 0, 0)           // First parameter is a name.
Print IndexedDir($str, 0, 0)           // First parameter is a name.
Print IndexedDir("IGOR", 0, 0)         // First parameter is a string.
Print IndexedDir(str, 0, 0)            // First parameter is a string.
```

The acceptance of a string is for backward compatibility only. New code should be written using a name.

The returned path uses the native conventions of the OS under which Igor is running.

Examples

Here is an example for heavy-duty Igor Pro programmers. This is a user-defined function that prints names of all folders in a given folder, with or without recursion.

To try it, copy and paste the `PrintFolders()` function into the Procedure window and compile it.

```
Function PrintFolders(pathName, full, recurse, level)
    String pathName    // Name of symbolic path in which to look for folders.
    Variable full       // True to print full paths instead of just folder name.
    Variable recurse    // True to recurse (do it for subfolders too).
    Variable level      // Recursion level. Pass 0 for the top level.

    Variable i
    String prefix
    // Build a prefix (a number of tabs to indicate the folder level by indentation)
    prefix = ""
    i = 0
    do
        if(i >= level)
            break
        endif
        prefix += "\t"           // Indent one more tab
        i += 1
    while(1)
    String path
    i = 0
    do
        path = IndexedDir($pathName, i, full)
        if(strlen(path) == 0)
            break               // No more folders
        endif
        Printf "%s%s\r", prefix, path
        if(recurse)              // Do we want to go into subfolder?
            String subFolderPathName = "tempPrintFoldersPath_" + num2istr(level+1)
            // Now we get the path to the new parent folder
            String subFolderPath
            if(full)
                subFolderPath = path           // We already have the full path.
            else
                PathInfo $pathName             // Only the folder name. Need to get full path.
                subFolderPath = S_path + path
            endif
            NewPath/Q/O $subFolderPathName, subFolderPath
            PrintFolders(subFolderPathName, full, recurse, level+1)
        endif
    do
```

```

        KillPath/Z $subFolderPathName
    endif
    i += 1
    while(1)
End

```

Once you have compiled the PrintFolders() function, execute the following command:

```
PrintFolders("Igor", 1, 1, 0)
```

IndexedFile

IndexedFile(pathName, index, fileTypeOrExtStr [, creatorStr])

The IndexedFile function returns a string containing the name of the *index*th file in the folder specified by *pathName* which matches the file type or extension specified by *fileTypeOrExtStr*.

Details

IndexedFile returns an empty string (" ") if there is no such file.

pathName is the *name* of an Igor symbolic path. It is *not* a string.

index normally starts from zero. However, if *index* is -1, IndexedFile returns a string containing a semicolon-separated list of the names of all files in the folder associated with the specified symbolic path which match *fileTypeOrExtStr*.

fileTypeOrExtStr is either:

- A string starting with ".", such as ".txt", ".bwav", or ".c". Only files with a matching file name extension are indexed. Set *fileTypeOrExtStr* to "." to index file names that end with "." such as "myFileNameEndsWithThisDot."
- A string containing exactly four characters, such as "TEXT" or "IGBW". Only files of the specified Macintosh file type are indexed. However, if *fileTypeOrExtStr* is "????", files of any type are indexed. On Windows, Igor considers files with ".txt" extensions to be of type TEXT. It does similar mappings for other extensions. See **File Types and Extensions** on page III-387 for details.

creatorStr is an optional string argument containing four characters such as "IGR0". Only files with the specified Macintosh creator code are indexed. Set *creatorStr* to "?????" to index all files (or omit the argument altogether). This argument is ignored on Windows systems.

Examples

```

NewPath/O myPath "MyDisk:MyFolder:"
Print IndexedFile(myPath,-1,"TEXT")           // all text-type files
Print IndexedFile(myPath,0,"TEXT")            // only the first text file
Print IndexedFile(myPath,-1,".dat")           // *.dat
Print IndexedFile(myPath,-1,"TEXT","IGR0")    // all Igor text files
Print IndexedFile(myPath,-1,"????")           // all files, all creators

```

See Also

The **TextFile** function.

IndexSort

IndexSort indexWaveName, sortedWaveName [, sortedWaveName]...

The IndexSort operation sorts the values in each *sortedWaveName* wave according to the Y values of *indexWaveName*.

Details

indexWaveName can not be complex. *indexWaveName* is presumed to have been the destination of a previous **MakeIndex** operation.

This has the effect of putting the *sortedWaveName* waves in the same order as the wave from which the index values in *indexWaveName* was made.

All of the *sortedWaveName* waves must be of equal length.

See Also

MakeIndex and **IndexSort** Operations on page III-135.

Inf

Inf

Inf

The Inf function returns the “infinity” value.

InsertPoints

InsertPoints [/M=*dim*] *beforePoint*, *numPoints*, *waveName* [, *waveName*]...

The InsertPoints operation inserts *numPoints* points in front of point *beforePoint* in each *waveName*. The new points have the value zero.

Flags

/M=*dim* Specifies the dimension into which elements are to be inserted. Values are 0 for rows, 1 for columns, 2 for layers, 3 for chunks. If /M is omitted, InsertPoints inserts in the rows dimension.

Details

Trying to insert points into any but the rows of a zero-point wave results in a zero-point wave. You must first make the number of rows nonzero before anything else has an effect.

See Also

Lists of Values on page II-82.

Integrate

Integrate [*type flags*] [*flags*] *yWaveA* [/X = *xWaveA*] [/D = *destWaveA*]
[, *yWaveB* [/X = *xWaveB*] [/D = *destWaveB*] [, ...]]

The Integrate operation calculates the numeric integral of a wave. X values may be supplied by the X-scaling of the source wave or by an optional X wave. Rectangular integration is used by default.

Flags

/DIM= *d* Specifies the wave dimension to integrate.
d=-1: Treats entire wave as 1D (default).
For *d*=0, 1, ..., operates along rows, columns, etc.
/METH=*m* Sets the integration method.
m=0: Rectangular integration (default). Results at a point are stored at the same point (rather than at the next point as for /METH=2). This method keeps the dimension size the same.
m=1: Trapezoidal integration.
m=2: Rectangular integration. Results at a point are stored at the next point (rather than at the same point as for /METH=0). This method increases the dimension size by one to provide a place for the last bin.
/P Forces point scaling.
/T Trapezoidal integration. Same as /METH=1.

Type Flags (used only in functions)

Integrate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Wave Parameters

Note: All wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name (Integrate).

/D=*destWave* Specifies the name of the wave to hold the integrated data. It creates *destWave* if it does not already exist or overwrites it if it exists.

/X=*xWave* Specifies the name of corresponding X wave. For rectangular integration, the number of points in the X wave must be one greater than the number of elements in the Y wave dimension being integrated.

Details

The computation equation for rectangular integration using /METH=0 is:

$$waveOut[p] = \sum_{i=0}^p waveIn[i] \cdot [x_{i+1} - x_i].$$

The computation equation for rectangular integration using /METH=2 is:

$$waveOut[0] = 0$$

$$waveOut[p+1] = \sum_{i=0}^p waveIn[i] \cdot [x_{i+1} - x_i].$$

The inverse of this rectangular integration is the backwards difference.

Trapezoidal integration (/METH=1) is a more accurate method of computing the integral than rectangular integration. The computation equation is:

$$waveOut[0] = 0$$

$$waveOut[p] = waveOut[p-1] + \frac{waveIn[p-1] + waveIn[p]}{2} \cdot [x_p - x_{p-1}].$$

If the optional /D = *destWave* flag is omitted, then the wave is integrated in place overwriting the source wave.

Unsigned integer waves are treated as if they were signed.

When using an X wave, the X wave must be a 1D wave with data type matching the Y wave (excluding the complex type flag). Rectangular integration (/METH=0 or 2) requires an X wave having one more point than the number of elements in the dimension of the Y wave being integrated. X waves with number points plus one are allowed for rectangular integration with methods needing only the number of points. X waves are not used with integer source waves.

Although it is mathematically suspect, rectangular integration using /METH=0 would be correct if the X scaling of the output wave is offset by ΔX .

Differentiate/METH=1/EP=1 is the inverse of Integrate/METH=2, but Integrate/METH=2 is the inverse of Differentiate/METH=1/EP=1 only if the original first data point is added to the output wave.

Integrate applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see **Sort**).

See Also

The **Differentiate** operation. The **integrate1D**, **area** and **areaXY** functions.

integrate1D

integrate1D(*UserFunctionName*, *min_x*, *max_x* [, *options* [, *count*]])

The **integrate1D** function performs numerical integration of a user function between the specified limits (*min_x* and *max_x*).

Parameters

UserFunctionName must have the following format:

```
Function UserFunctionName(inX)
  Variable inX
  ... do something
  return result
End
```

options is one of the following:

- 0: Trapezoidal integration (default).
- 1: Romberg integration.
- 2: Gaussian Quadrature integration.

By default, *options* is 0 and the function performs trapezoidal integration. In this case Igor evaluates the integral iteratively. In each iteration the number of points where Igor evaluates the function increases by a factor of 2. The iterations terminate at convergence to tolerance or when the number of evaluations is 2^{23} .

The *count* parameter specifies the number of subintervals in which the integral is evaluated. If you specify 0 or a negative number for count, the function performs an adaptive Gaussian Quadrature integration in which Igor bisects the interval and performs a recursive refining of the integration only in parts of the interval where the integral does not converge to tolerance.

Details

You can integrate complex-valued functions using a function with the format:

```
Function/C complexUserFunction(inX)
    Variable inX
    Variable/C result
    //... do something
    return result
End
```

The syntax used to invoke the function is:

```
Variable/C cIntegralResult=Integrate1D(complexUserFunction,min_x,max_x...)
```

You can also use `integrate1D` to perform a higher dimensional integrals. For example, consider the function: $F(x,y) = 2x + 3y + xy$.

In this case, the integral $h = \int dy \int f(x,y) dx$ can be performed by establishing two user functions:

```
Function do2dIntegration(xmin,xmax,ymin,ymax)
    Variable xmin,xmax,ymin,ymax
    Variable/G globalXmin=xmin
    Variable/G globalXmax=xmax
    Variable/G globalY
    return Integrate1D(userFunction2,ymin,ymax,1)    // Romberg integration
End

Function userFunction1(inX)
    Variable inX
    NVAR globalY=globalY
    return (3*inX+2*globalY+inX*globalY)
End

Function userFunction2(inY)
    Variable inY
    NVAR globalY=globalY
    globalY=inY
    NVAR globalXmin=globalXmin
    NVAR globalXmax=globalXmax
    // Romberg integration
    return integrate1D(userFunction1,globalXmin,globalXmax,1)
End
```

This method can be extended to higher dimensions.

If the integration fails to converge or if the integrand diverges, `integrate1D` returns NaN. When a function fails to converge it is a good idea to try another integration method or to use a user-defined number of intervals (as specified by the *count* parameter). Note that the trapezoidal method is prone to convergence problems when the absolute value of the integral is very small.

See Also

The **Integrate** operation.

IntegrateODE

IntegrateODE [*flags*] *derivFunc*, *cwaveName*, *ywaveSpec*

The **IntegrateODE** operation calculates a numerical solution to a set of coupled ordinary differential equations by integrating derivatives. The derivatives are user-specified via a user-defined function,

derivFunc. The equations must be a set of first-order equations; a single second-order equation must be recast as two first-order equations, a third-order equation to three first order equations, etc. For more details on how to write the function, see **Solving Differential Equations** on page III-262.

IntegrateODE offers two ways to specify the values of the independent variable (commonly called X or t) at which output Y values are recorded. You can specify the X values or you can request a “free-run” mode.

The algorithms used by IntegrateODE calculate results at intervals that vary according to the characteristics of the ODE system and the required accuracy. You can set specific X values where you need output (see the /X flag below) and arrangements will be made to get values at those specific X values. In between those values, IntegrateODE will calculate whatever spacing is needed, but intermediate values will not be output to you.

If you specify free-run mode, IntegrateODE will simply output all steps taken regardless of the spacing of the X values that results.

Parameters

<i>cwaveName</i>	Name of wave containing constant coefficients to be passed to <i>derivFunc</i> .
<i>derivFunc</i>	Name of user function that calculates derivatives. For details on the form of the function, see Solving Differential Equations on page III-262.
<i>ywaveSpec</i>	Specifies a wave or waves to receive calculated results. The waves also contain initial conditions. The <i>ywaveSpec</i> can have either of two forms: <div style="margin-left: 20px;"> <i>ywaveName</i> <i>ywaveName</i> is a single, multicolumn wave having one column for each equation in your equation set (if you have just one equation, the wave will be a simple 1D wave). <i>{ywave0, ywave1, ...}</i> The <i>ywaveSpec</i> is a list of 1D waves, one wave for each equation. The ordering is important — it must correspond to the elements of the y wave and dydx wave passed to <i>derivFunc</i>. Unless you use the /R flag to alter the start point, the solution to the equations is calculated at each point in the waves, starting with row 1. You must store the initial conditions in row 0. </div>

Flags

<i>/CVOP={solver, jacobian, extendedErrors}</i>	<p>Selects options that affect how the Adams-Moulton and BDF integration schemes operate. This flag applies only when using /M = 2 or /M = 3. These methods are based on the CVODE package, hence the flag letters “CV”.</p> <p>The <i>solver</i> parameter selects a solver method for each step. The values of <i>solver</i> can be:</p> <p><i>solver=0:</i> Select the default for the integration method. That is functional for /M=2 or Newton for /M=3.</p> <p><i>solver=1:</i> Functional solver.</p> <p><i>solver=2:</i> Newton solver.</p> <p>The <i>jacobian</i> parameter selects the method used to approximate the jacobian matrix (matrix of df/dy_i where <i>f</i> is the derivative function).</p> <p><i>jacobian=0:</i> Full jacobian matrix.</p> <p><i>jacobian=1:</i> Diagonal approximation.</p> <p>In both cases, the derivatives are approximated by finite differences.</p> <p>In our experience, <i>jacobian</i> = 1 causes the integration to proceed by much smaller steps. It might decrease overall integration time by reducing the computation required to approximate the jacobian matrix.</p> <p>If the <i>extendedErrors</i> parameter is nonzero, extra error information will be printed to the history window in case of an error during integration using /M=2 or /M=3. This extra information is mostly of the sort that will be meaningful only to WaveMetrics software engineers, but may occasionally help you to solve problems. It is printed out as a bug message (BUG: ...) regardless of whether it is our bug or yours.</p>
<i>/E=eps</i>	<p>Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a fraction of a scaled number. The fraction is <i>eps</i>. For instance, to achieve error less than one part in a thousand, set <i>eps</i> to 0.001. The number itself is</p>

	set by a combination of the /F flag and possibly the wave specified with the /S flag. See Solving Differential Equations on page III-262 for details.
	If you do not use the /E flag, <i>eps</i> is set to 10^{-6} .
	For details, see Error Monitoring on page III-271.
/F= <i>errMethod</i>	Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a scaled number. <i>errMethod</i> is a bitwise value that specifies what to include in that number: bit 0: Add a constant from the error scaling wave set by the /S flag. bit 1: Add the current value of the results. bit 2: Add the current value of the derivatives. bit 3: Multiply by the current step size (/M=0 or /M=1 only). Each bit that you set of bits 0, 1, or 2 adds a term to the number; setting bit 3 multiplies the sum by the current step size to achieve a global error limit. Note that bit 3 has no effect if you use the Adams or BDF integrators (/M=2 or /M=3). See Setting Bit Parameters on page IV-11 for further details about bit settings. If you don't include the /F flag, a constant is used. Unless you use the /S flag, that constant is set to 1.0.
/M= <i>m</i>	For details, see Error Monitoring on page III-271. Specifies the method to use in calculating the solution. <i>m</i> =0: Fifth-order Runge-Kutta-Fehlberg (default). <i>m</i> =1: Bulirsch-Stoer method using Richardson extrapolation. <i>m</i> =2: Adams-Moulton method. <i>m</i> =3: BDF (Backwards Differentiation Formula, or Gear method). This method is the preferred method for stiff problems. If you don't specify a method, the default is the Runge-Kutta method (<i>m</i> =0). Bulirsch-Stoer (<i>m</i> =1) should be faster than Runge-Kutta for problems with smooth solutions, but we find that this is often not the case. Simple experiments indicate that Adams-Moulton (<i>m</i> =2) may be fastest for nonstiff problems. BDF (<i>m</i> =3) is definitely the preferred one for stiff problems. Runge-Kutta is a robust method that may work on problems that fail with other methods.
/Q [= <i>quiet</i>]	<i>quiet</i> = 1 or simply /Q sets quiet mode. In quiet mode, no messages are printed in the history, and errors do not cause macro abort. The variable <i>V_flag</i> returns an error code. See Details for the meanings of the <i>V_flag</i> error codes.
/R=(<i>startX</i> , <i>endX</i>)	Specifies an X range of the waves in <i>ywaveSpec</i> .
/R=[<i>startP</i> , <i>endP</i>]	Specifies a point range in <i>ywaveSpec</i> . If you specify the range as /R=[<i>startP</i>] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is evaluated. If you specify only the end point (/R = [, <i>endP</i>]) the start point is taken as point 0. You must store initial conditions in <i>startP</i> . The first point is <i>startP</i> +1.
/S= <i>errScaleWaveName</i>	If you set bit 0 of <i>errMethod</i> using the /F flag, or if you don't include the /F flag, a constant is required for scaling the estimated error for each differential equation. By default, the constants are simply set to 1.0. You provide custom values of the constants via the /S flag and a wave. Make a wave having one element for each derivative, set a reasonable scale factor for the corresponding equation, and set <i>errScaleWaveName</i> to the name of that wave. If you don't use the /S flag, the constants are all set to 1.0.
/U= <i>u</i>	Update the display every <i>u</i> points. By default, it will update the display every 10 points. To disable updates, set <i>u</i> to a very large number.
/X= <i>xvaluespec</i>	Specifies the values of the independent variable (commonly called <i>x</i> or <i>t</i>) at which values are to be calculated (see parameter <i>ywaveSpec</i>). You can provide a wave or <i>x0</i> and <i>deltaX</i> : /X = <i>xWaveName</i>

Use this form to provide a list of values for the independent variable. They can have arbitrary spacing and may increase or decrease, but should be monotonic.

If you use the `/XRUN` flag to specify free-run mode, `/X = xWaveName` is required. In this case, the X wave becomes an output wave and any contents are overwritten. See the description of `/XRUN` for details.

`xValues = {x0, deltaX}`

If you use this form, `x0` is the initial value of the independent variable. This is the value at which the initial conditions apply. It will calculate the first result at `x0+deltaX`, and subsequent results with spacing of `deltaX`.

`deltaX` can be negative.

If you do not use the `xValues` keyword, it reads independent variable values from the X scaling of the results wave (see `ywaveSpec` parameter).

`/XRUN={dx0, Xmax}`

If `dx0` is nonzero, the output is generated in a free-running mode. That is, the output values are generated at whatever values if the independent variable (`x` or `t`) the integration method requires to achieve the requested accuracy. Thus, you will get solution points at variably-spaced X values.

The parameter `dx0` sets the step size for the first integration step. If this is smaller than necessary, the step size will increase rapidly. If it is too large for the requested accuracy, the integration method will decrease the step size as necessary.

If `dx0` is set to zero, free-run mode is not used; this is the same as if the `XRUN` flag is not used.

When using free-run mode, you must provide an X wave using `/X = xWaveName`. Set the first value of the wave (this is usually point zero, but may not be if you use the `/R` flag) to the initial value of X.

As the integration proceeds, the X value reached for each output point is written into the X wave. The integration stops when the latest step taken goes beyond `Xmax` or when the output waves are filled.

Details

The various waves you may use with the IntegrateODE operation must meet certain criteria. The wave to receive the results (`ywaveSpec`), and which contains the initial conditions, must have exactly one column for each equation in your system of equations, or you must supply a list of waves containing one wave for each equation. Because IntegrateODE can't determine how many equations there are from your function, it uses the number of columns or the number of waves in the list to determine the number of equations.

If you supply a list of waves for `ywaveSpec`, all the waves must have the same number of rows. If you supply a wave containing values of the independent variable or to receive X values in free-run mode (using `/X=waveName`) the wave must have the same number of rows as the `ywaveSpec` waves.

The wave you provide for error scaling via the `/S` flag must have one point for each equation. That is, one point for each `ywaveSpec` wave, or one point for each column of a multicolumn `ywaveSpec`.

By default, the display will update after each tenth point is calculated. If you display one of your `ywaveSpec` waves in a graph, you can watch the progress of the integration.

The display update may slow down the calculation considerably. Use the `/U` flag to change the interval between updates. To disable the updates entirely, set the update interval to a number larger than the length of the waves in `ywaveSpec`.

In free-run mode, it is impossible to predict how many output values you will get. IntegrateODE will stop when either your waves are filled, or when the X value exceeds `Xmax` set in the `/XRUN` flag. The best strategy is to make the waves quite large; unused rows in the waves will not be touched. To avoid having "funny" traces on a graph, you can prefill your waves with NaN. Make sure that you don't set the initial condition row and initial X value row to NaN!

The IntegrateODE operation sets a variety of variables to give you information about the integration. These variables are updated at the same time as the display so you can monitor an integration in progress. They are:

<code>V_ODEStepCompleted</code>	Point number of the last result calculated.
<code>V_ODEStepSize</code>	Size of the last step in the calculation.

interp

V_ODETTotalSteps	Total number of steps required to arrive at the current result. In free-run mode, this is the same as V_ODEStepCompleted.
V_ODEMinStep	Minimum step size used during the entire calculation.
V_ODEFunctionCalls	The total number of calls made to your derivative function.

In Quiet mode (see the /Q flag) an V_Flag is set when IntegrateODE stops to indicate why it stopped:

V_flag	Set only in Quiet mode. Value indicates reason that IntegrateODE stopped. The values are: 0: Finished normally. 1: User aborted the integration. 2: Integration stopped because the step size became too small. That is, dX was so small that $X + dX = X$. 3: IntegrateODE ran out of memory. 4: In /M=2 or /M=3, the integrator received illegal inputs. Please report this to WaveMetrics (see Technical Support on page II-13 for contact details). 5: In /M=2 or /M=3, the integrator stopped with a failure in the step solver. The method chosen may not be suitable to the problem. 6: Indicates a bug in IntegrateODE. Please report this to WaveMetrics (see Technical Support on page II-13 for contact details). 7: An error scaling factor was zero (see /S and /F flags).

References

The Runge-Kutta (/M=0) and Bulirsh-Stoer (/M=1) methods are based on routines in Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992, and are used by permission.

The Adams-Moulton (/M=2) and BDF methods (/M=3) are based on the CVODE package developed at Lawrence Livermore National Laboratory:

Cohen, Scott D., and Alan C. Hindmarsh, *CVODE User Guide*, LLNL Report UCRL-MA-118618, September 1994.

The CVODE package was derived in part from the VODE package. The parts used in Igor are described in this paper:

Brown, P.N., G. D. Byrne, and A. C. Hindmarsh, VODE, a Variable-Coefficient ODE Solver, *SIAM J. Sci. Stat. Comput.*, 10, 1038-1051, 1989.

interp

interp(x1, xwaveName, ywaveName)

The interp function returns a linearly interpolated value at the location $x = x1$ of a curve whose X components come from the Y values of *xwaveName* and whose y components come from the Y values of *ywaveName*.

Details

interp returns nonsense if the waves are complex or if *xwaveName* is not monotonic.

The interp function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

Examples

See Also

The Interpolate XOP can also do linear as well as spline interpolation.

Other solutions are available for multidimensional interpolation. **ImageInterpolate** and **Interp3DPath** operations for interpolation of higher dimensions. The **ContourZ** function performs linear interpolation of matrices or nongridded XYZ triples. The MDInterpolator XOP file, shipped in the More Extensions folder, implements the **interp2D** and **interp3D** external functions. See the section **Igor Extensions** on page III-407 for details about installing and using XOPs. **Interpolation** on page III-120.

See Also

The **Loess** operation.

Interp2D

Interp2D(srcWaveName, xValue, yValue)

The **Interp2D** function returns a double precision number as the interpolated value for the *xValue*, *yValue* point in the source wave. Returns NaN if the point is outside the source wave domain or if the source wave is complex.

Parameters

srcWaveName is the name of a 2D wave. The wave can not be complex.

xValue is the X-location of the interpolated point.

yValue is the Y-location of the interpolated point.

See Also

The **ImageInterpolate** operation. **Interpolation** on page III-120.

Interp3d

Interp3d(srcWave, x, y, z [, triangulationWave])

The **Interp3d** function returns an interpolated value for location $P=(x, y, z)$ in a 3D scalar distribution *srcWave*.

If *srcWave* is a 3D wave containing a scalar distribution sampled on a regular lattice, the function returns a linearly interpolated value for any $P=(x, y, z)$ location within the domain of *srcWave*. If *P* is outside the domain, the function returns NaN.

To interpolate a 3D scalar distribution that is not sampled on a regular lattice, *srcWave* is a four column 2D wave where the columns correspond to $x, y, z, f(z, y, z)$, respectively. You must also use a “triangulation” wave for *srcWave* (use **Triangulate3D/out=1** to obtain the triangulation wave). If *P* falls within the convex domain defined by the tetrahedra in *triangulationWave*, the function returns the barycentric linear interpolation for *P* using the tetrahedron where *P* is found. If *P* is outside the convex domain the function returns NaN.

Examples

```
Make/O/N=(10,20,30) ddd=gnoise(10)
Print interp3d(ddd,1,0,0)
Print interp3d(ddd,1,1,1)

Make/O/N=(10,4) ddd=gnoise(10)
Triangulate3D/OUT=1 ddd
Print interp3d(ddd,1,0,0,M_3dVertexList)
Print interp3d(ddd,1,1,1,M_3dVertexList)
```

Interp3DPath

See Also

The **Interpolate3D** operation. **Interpolation** on page III-120.

Interp3DPath

Interp3DPath *3dWave tripletPathWave*

The **Interp3DPath** operation computes the trilinear interpolated values of *3dWave* for each position specified by a row of in *tripletPathWave*, which is a three-column wave in which the first column represents the X coordinate, the second represents the Y coordinate and the third represents the Z coordinate. **Interp3DPath** stores the resulting interpolated values in the wave *W_Interpolated*. **Interp3DPath** is equivalent to calling the **Interp3D()** function for each row in *tripletPathWave* but it is computationally more efficient.

If the position specified by the *tripletPathWave* is outside the definition of the *3dWave* or if it contains a NaN, the operation stores a NaN in the corresponding output entry.

Both *3dWave* and *tripletPathWave* can be of any numeric type. *W_Interpolated* is always of type NT_FP64.

See Also

The **ImageInterpolate** operation and the **Interp3d** and **interp** functions. **Interpolation** on page III-120.

Interpolate3D

Interpolate3D [*/Z*] */RNGX={x0,dx,nx}/RNGY={y0,dy,ny}/RNGZ={z0,dz,nz}* */DEST=dataFolderAndName, triangulationWave=tWave, srcWave=sWave*

The **Interpolate3D** operation uses a precomputed triangulation of *sWave* (see **Triangulate3d**) to calculate regularly spaced interpolated values from an irregularly spaced source. The interpolated values are calculated for a lattice defined by the range flags */RNGX*, */RNGY*, and */RNGZ*. *sWave* is a 4 column wave where the first three columns contain the spatial coordinates and the fourth column contains the associated scalar value. **Interpolate3D** is essentially equivalent to calling the **Interp3d** function for each interpolated point in the range but it is much more efficient.

Parameters

triangulationWave=tWave

Specifies a 2D index wave, *tWave*, in which each row corresponds to one tetrahedron and each column (tetrahedron vertex) is represented by an index of a row in *sWave*. Use **Triangulate3d** with */OUT=1* to obtain *tWave*.

srcWave=sWave

Specifies a real-valued 4 column 2D source wave, *sWave*, in which columns correspond to *x*, *y*, *z*, *f(x, y, z)*. Requires that the domain occupied by the set of *{x, y, z}* be convex.

Flags

/DEST=dataFolderAndName

Saves the result in the specified destination wave. The destination wave will be created or overwritten if it already exists. *dataFolderAndName* can include a full or partial path with the wave name.

/RNGX={x0,dx,nx}

Specifies the range along the X-axis. The interpolated values start at *x0*. There are *nx* equally spaced interpolated values where the last value is at *x0+(nx-1)dx*. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a YZ plane would have *nx=1*.

/RNGY={y0,dy,ny}

Specifies the range along the Y-axis. The interpolated values start at *y0*. There are *ny* equally spaced interpolated values where the last value is at *y0+(ny-1)dy*. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XZ plane would have *ny=1*.

/RNGZ={z0,dz,nz}

Specifies the range along the Z-axis. The interpolated values start at *z0*. There are *nz* equally spaced interpolated values where the last value is at *z0+(nz-1)dz*. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XY plane would have *nz=1*.

/Z

No error reporting.

Details

The triangulation wave defines a set of tetrahedra that spans the convex source domain. If the requested range consists of points outside the domain, the interpolated values will be set to NaN. The interpolation process for

points inside the convex domain consists of first finding the tetrahedron in which the point resides and then linearly interpolating the scalar value using the barycentric coordinate of the interpolated point.

The **Triangulate3d** operation and the **Interp3d** function. **Interpolation** on page III-120.

References

Schneider, P.J., and D. H. Eberly, *Geometric Tools for Computer Graphics*, Morgan Kaufmann, 2003.

inverseErf

inverseErf(x)

The inverseErf function returns the inverse of the error function.

Details

The function is calculated using rational approximations in several regions followed by one iteration of Halley's algorithm.

See Also

The **erf**, **erfc**, **dawson**, and **inverseErfc** functions.

inverseErfc

inverseErfc(x)

The inverseErfc function returns the inverse of the complementary error function.

Details

The function is calculated using rational approximations in several regions followed by one iteration of Halley's algorithm.

See Also

The **erf**, **erfc**, **dawson**, and **inverseErf** functions.

ItemsInList

ItemsInList(listStr [, listSepStr])

The ItemsInList function returns the number of items in *listStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use ItemsInList to count the number of items in a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

If *listStr* is "" then 0 is returned.

listSepStr is optional. If missing, *listSepStr* is presumed to be ";".

Details

listStr is searched for item strings bound by *listSepStr* on the left and right.

An item can be empty. The lists "abc;def;;ghi" and ";abc;def;;ghi;" have four items (the third item is "").

listStr is treated as if it ends with a *listSepStr* even if it doesn't. The search is case-sensitive.

Only the first character of *listSepStr* is used.

Examples

```
Print ItemsInList("wave0;wave1;wave1#1;")           // prints 3
Print ItemsInList("key1=val1,key2=val2", ",")        // prints 2
Print ItemsInList("1 \t 2 \t", "\t")                // prints 2
Print ItemsInList(";")                              // prints 1
Print ItemsInList(";;")                             // prints 2
Print ItemsInList(";a;")                             // prints 2
Print ItemsInList(";;;")                             // prints 3
```

j

See Also

The **AddListItem**, **StringFromList**, **FindListItem**, **RemoveFromList**, **WaveList**, **TraceNameList**, **StringList**, **VariableList**, and **FunctionList** functions.

j

j

The j function returns the loop index of the 2nd innermost iterate loop in a macro. Not to be used in a function. Iterate loops are archaic and should not be used.

jlim

jlim

The jlim function returns the ending loop count for the 2nd inner most iterate loop. Not to be used in a function. Iterate loops are archaic and should not be used.

JulianToDate

JulianToDate(*julianDay*, *format*)

The JulianToDate function returns a date string containing the day, month, and year. The input *julianDay* is truncated to an integer.

Parameters

julianDay is the Julian day to be converted.

format specifies the format of the returned date string.

<i>format</i>	Date String
0	mm/dd/year
1	dd/mm/year
2	Tuesday November 15, 2002
3	year mm dd
4	year/mm/dd

See Also

The **dateToJulian** function.

For more information about the Julian calendar see: <<http://www.tondering.dk/claus/cal/>>.

KillBackground

KillBackground

The KillBackground operation kills the background task.

Details

You can not call KillBackground from within the background function itself. However, if you return 1 from the background function, instead of the normal 0, Igor will terminate the background task.

See Also

The **BackgroundInfo**, **CtrlBackground**, **CtrlNamedBackground**, **SetBackground**, and **SetProcessSleep** operations; and **Background Task** on page IV-211.

KillControl

KillControl [/W=*winName*] *controlName*

The KillControl operation kills the named control in the top or specified graph or panel window or subwindow.

If the named control does not exist, KillControl does not complain.

Flags

/W=*winName* Looks for the control in the named graph or panel window or subwindow. If /W is omitted, KillControl looks in the top graph or panel window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

KillDataFolder

KillDataFolder [/Z] *dataFolderSpec*

The KillDataFolder operation kills the specified data folder and everything in it including other data folders.

Flags

/Z No error reporting (except for setting V_flag). Does not halt function execution.

Parameters

dataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

If specified data folder is the current data folder or contains the current data folder then Igor makes its parent the new current data folder.

It is legal to kill the root data folder. In this case the root data folder itself is not killed but everything in it is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed. Execution ceases unless /Z is specified.

The variable V_flag is set to 0 when there is no error, otherwise it is an error code.

Examples

```
KillDataFolder foo           // Kills foo in the current data folder.
KillDataFolder :bar:foo      // Kills foo in bar in current data folder.
String str= "root:foo"
KillDataFolder $str          // Kills foo in the root data folder.
```

See Also

Chapter II-8, **Data Folders** and the **KillStrings**, **KillVariables**, and **KillWaves** operations.

KillFIFO

KillFIFO *FIFOName*

The KillFIFO operation discards the named FIFO.

Details

FIFOs are used for data acquisition.

If there is an output or review file associated with the FIFO, KillFIFO closes the file. If the FIFO is used by an XOP, you should call the XOP to release the FIFO before killing it.

See Also

See **FIFOs and Charts** on page IV-208 for information about FIFOs and data acquisition.

KillFreeAxis

KillFreeAxis [/W=*winName*] *axisName*

The KillFreeAxis operation removes a free axis specified by *axisName* from a graph window or subwindow.

Flags

/W=*winName* Kills the free axis in the named graph window or subwindow. If /W is omitted, it acts on the top graph window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

KillPath

Details

Only an axis created by **NewFreeAxis** can be killed and only if no traces or images are attached to the axis.

See Also

The **NewFreeAxis** operation.

KillPath

KillPath [/A/Z] *pathName*

The KillPath operation removes a path from the list of symbolic paths. KillPath is a newer name for the **RemovePath** operation.

Flags

- /A Kills all symbolic paths in the experiment except for the built-in paths. Omit *pathName* if you use /A.
- /Z Does not generate an error if a path to be killed is a built-in path or does not exist. To kill all paths in the experiment, use **KillPath/A/Z**.

Details

You can't kill the built-in paths "home" and "Igor".

KillPICTs

KillPICTs [/A/Z] [*PICTName* [, *PICTName*]...]

The KillPICTs operation removes one or more named pictures from the current Igor experiment.

Flags

- /A Kills all pictures in the experiment.
- /Z Does not generate an error if a picture to be killed is in use or does not exist. To kill all pictures in the experiment, use **KillPICTs/A/Z**.

Details

You can not kill a picture that is used in a graph or page layout.

Warning: You *can* kill a picture that is referenced from a graph or layout recreation macro. If you do, the graph or layout can not be completely recreated. Use the Find dialog (Edit menu) to locate references in the procedure window to a named picture you want to kill.

See Also

See **Pictures** on page III-405 for general information on how Igor handles pictures.

KillStrings

KillStrings [/A/Z] [*stringName* [, *stringName*]...]

The KillStrings operation discards the named global strings.

Flags

- /A Kills all global strings in the current data folder. If you use /A, omit *stringName*.
- /Z Does not generate an error if a global string to be killed does not exist. To kill all global strings in the current data folder, use **KillStrings/A/Z**.

KillVariables

KillVariables [/A/Z] [*variableName* [, *variableName*]...]

The KillVariables operation discards the named global numeric variables.

Flags

- /A Kills all global variables in the current data folder. If you use /A, omit *variableName*.
- /Z Does not generate an error if a global variable to be killed does not exist. To kill all global variables in the current data folder, use **KillVariables/A/Z**.

KillWaves

KillWaves [*flags*] *waveName* [, *waveName*]...

The KillWaves operation destroys the named waves.

Flags

/A Kills all waves in the current data folder. If you use /A, omit *waveNames*.
 /F Deletes the Igor binary file from which *waveName* was loaded.
 /Z Does not generate an error if a wave to be killed is in use or does not exist.

Details

The memory the waves occupied becomes available for other uses. You can't kill a wave used in a graph, table or user defined function, or which is reserved by an XOP.

XOPs reserve a wave by sending the OBJINUSE message.

Examples

```
KillWaves/A/Z            // kill waves not in use in current data folder
```

KillWindow

KillWindow *winName*

The KillWindow operation kills or closes a specified window or subwindow without saving a recreation macro.

Parameters

winName is the name of an existing window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

The **DoWindow** operation.

KMeans

KMeans [*flags*] *populationWave*

The KMeans operation analyzes the clustering of data in *populationWave* using an iterative algorithm. The result of KMeans is a specification of the classes which is saved in the wave M_KMClasses in the current data folder. Optional results include the distribution of class members (W_KMMembers) and the inter-class distances. *populationWave* is a 2D wave in which columns correspond to members of the population and rows contain the dimensional information.

Flags

/CAN Analyzes the clustering by computing Euclidean distances between the means of the resulting classes. The resulting distances are stored in an NxN square matrix where N is the number of classes. Self distances (along the diagonal) or distances involving classes that did not survive the iterations are filled with NaN. Also saves the wave W_KMDispersion, which contains the sum of the distances between the center of each class and all its members. Distances are evaluated using the method specified by /DIST.

/DEAD=*method* Specifies how the algorithm should handle "dead" classes, which are those that lose all members in a given iteration.

method=1: Remove the class if it loses all members.

method=2: Default; keeps the last value of the mean vector in case the class might get new members in a subsequent iteration.

method=3: Assigns the class a random mean vector.

/DIST=*mode* Specifies how the class distances are evaluated.

mode=1: Distance is evaluated as the sum of the absolute values (also known as Manhattan distance).

mode=2: Default; distance is evaluated as Euclidean distance.

/INIT=*method* Specifies the initialization method.

method=1: Random assignment of members of the population to a class.

	<i>method=2:</i> User-specified mean values (/INW).
	<i>method=3:</i> Default; initialize classes using values of a random selection from the population.
/INW= <i>iWave</i>	Sets the initial classes. The number of rows of <i>iWave</i> equals the dimensionality of the class and the number of columns of <i>iWave</i> is the number of classes. For example, if we want to initialize 5 classes in a problem that involves position in two dimensions then <i>iWave</i> must have 2 rows and 5 columns. The number of rows must also match the number of rows in <i>populationWave</i> .
/NCLS= <i>num</i>	Sets the number of classes in the data. If the initialization method uses specific means (/INIT=2) then the number of columns of <i>iWave</i> (see /INW) must match <i>num</i> . The default number of classes is 2.
/OUT= <i>format</i>	Specifies the format for the results. <i>format=1:</i> Output only the specification of the classes in the 2D wave M_KMClasses (default). Each column in M_KMClasses represents a class. The number of rows in M_KMClasses is equal to the number of rows in <i>populationWave</i> +1. The last row contains the number of class members. The remaining rows represent the center of the class. For example, if <i>populationWave</i> has two rows then the dimensionality of the problem is 2 and M_KMClasses has 3 rows with the first row containing the first components of each class center, the second row containing the second components of each class center and the third row containing the number of elements in each class. <i>format=2:</i> Output (in addition to M_KMClasses) the class membership in the wave W_KMMembers. The rows in this 1D wave correspond to sequential members of <i>populationWave</i> and the entries correspond to the (zero based) column number in M_KMClasses.
/SEED= <i>val</i>	Sets the seed for a new sequence in the pseudo-random number generator that is used by the operation. By changing the sequence you may be able to find new solutions or just make the process converge at a different rate.
/TER= <i>method</i>	Determines when the iterations stop. <i>method=1:</i> User-specified number of iterations (/TERN). <i>method=2:</i> Default; continue iterating until no more than a fixed number of elements change classes in one iteration (TERN).
/TERN= <i>num</i>	Specifies the termination number. The meaning of the number is determined by /TER above. By default, the termination <i>method=2</i> and the default value of the maximum number of elements that change classes in one iteration is 5% of the size of the population.
/Z	No error reporting. If an error occurs, sets V_flag to -1 but does not halt function execution.

Details

KMeans uses an iterative algorithm to analyze the clustering of data. The algorithm is not guaranteed to find a global optimum (maximum likelihood solution) so the operation provides various flags to control when the iterations terminate. You can determine if the operation iterates a fixed number of times or loops until at most a specified maximum number of elements change class membership in a single iteration. If you are computing KMeans in more than one dimension you should pay attention to the relative magnitudes of the data in each dimension. For example, if your data is distributed on the interval [0,1] in the first dimension and on the interval [0,1e7] in the second dimension, the operation will be biased by the much larger magnitude of values in the second dimension.

Examples

Create data with 3 classes:

```
Make/O/N=(1,128) jack=4+gnoise(1)
jack[0][15,50]+=10
jack[0][60,]+=20
```

Perform KMeans looking for 5 classes:

```
KMeans/init=1/out=1/ter=1/dead=1/tern=1000/ncls=5 jack
Print M_KMClasses
```

```
M_KMClasses[0][0]= {24.1439,68}
M_KMClasses[0][1]= {14.1026,36}
M_KMClasses[0][2]= {4.01537,24}
```

<http://www.ece.neu.edu/groups/rpl/projects/kmeans/index.html>.

Label

Label [*/W=winName/Z*] *axisName*, *labelStr*

The Label operation labels the named axis with *labelStr*.

Parameters

axisName is the name of an existing axis in the top graph. It is usually one of “left”, “right”, “top” or “bottom”, though it may also be the name of a free axis such as “VertCrossing”.

labelStr contains the text that labels the axis.

Flags

/W=winName Adds axis label in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z No errors generated if the named axis doesn’t exist. Used for style macros.

Details

labelStr can contain the following escape codes which affect subsequent characters in the string:

\B Use subscript (in smaller type).
\F'fontName' Use specified font (e.g., *\F'Helvetica'*).
\fdd *dd* is a binary coded number with each bit controlling one aspect of the column’s font style as follows:

- bit 0: Bold.
- bit 1: Italic.
- bit 2: Underline.
- bit 3: Outline (*Macintosh only*).
- bit 4: Shadow (*Macintosh only*).

For example, bold underline is $2^0 + 2^2 = 1 + 4 = 5$. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

\K(r,g,b) Use specified color for text. *r*, *g*, and *b* are integers from 0 to 65535.

\M Use normal script (reverts to main line and font size).

\S Use superscript (in smaller type).

\Znn Use font size *nn*, which must be exactly two digits.

labelStr can also contain the following special codes that insert dynamically computed substrings:

\c Inserts the name of the wave that controls the axis. This is the first wave graphed against that axis.

\E Inserts power of 10 scaling with leading x. This can be ambiguous; we recommend that you use either *\U* or *\u*.

\e Like *\E* but inverts the sign of the exponent. Even more ambiguous than *\E*.

\s(traceName) Inserts a wave symbol for the named trace.

\U Inserts units with automatic prefixes.

\u Inserts power of 10 scaling but without the leading x as used by *\E*. No action if axis is not scaled. Use in front of custom or compound unit strings. Example label: “Field

	<code>Strength (\\u Volts/Meter)</code> will produce something like “Field Strength (10 ⁶ Volts/Meter)”.
<code>\\u#1</code>	This is a variant of <code>\\u</code> that inserts the inverse of <code>\\u</code> (e.g., 10 ⁻⁶ instead of 10 ⁶).
<code>\\u#2</code>	Prevents automatic insertion of any units or scaling. Normally, if you set a wave’s units and scaling, using the Change Wave Scaling dialog or SetScale operation, and if you do not explicitly specify an axis label, Igor will automatically generate an axis label from the units and scaling. <code>\\u#2</code> provides a way to suppress this behavior when it gets in the way.

labelStr can also contain escape codes to manipulate text info variables (see **Escape Characters in Strings** on page IV-13).

Note that escape codes are case sensitive; `\\u` and `\\U` insert different substrings.

Each backslash character should be preceded with another backslash. This is because backslash is itself a special escape character for strings. Future Igor Pro versions may require this double-backslash syntax; currently either the single or double backslash are acceptable synonyms for inserting a single backslash into a string. For example:

```
String myStr = "\\\"
Print myStr           // Prints \ to the history area
```

myStr was set to a *single* backslash character. See **Escape Characters in Strings** on page IV-13 for more about the backslash character. This behavior affects how escape sequences in *labelStr* should be written:

```
Label top, "\\z14Stuff"      // no: In future, may come out as "z14Stuff"
Label top, "\\z14Stuff"     // yes
```

You can see how *labelStr* should be constructed by using the Axis Label tab and observing the command it creates. You will observe many double backslash sequences. Single backslash sequences are deprecated, and are currently accepted for backward compatibility reasons.

The characters “<??>” in an axis label indicate that you specified an invalid escape code or used a font that is not available.

See Also

See **About Text Info Variables** on page III-61 for *labelStr* escape codes that manipulate text info variables. See **Escape Characters in Strings** on page IV-13 for more about the backslash character. See the **Legend** operation about wave symbols.

laguerre

laguerre(*n*, *x*)

The **laguerre** function returns the Laguerre polynomial of degree *n* (positive integer) and argument *x*. The polynomials satisfy the recurrence relation:

$$(n+1)Laguerre(n+1,x) = (2n+1-x)Laguerre(n,x) - nLaguerre(n-1,x)$$

with the initial conditions $Laguerre(0,x) = 1$ and $Laguerre(1,x) = 1-x$.

See Also

The **chebyshev**, **chebyshevU**, **hermite**, **hermiteGauss**, and **legendreA** functions.

laguerreA

laguerreA(*n*, *k*, *x*)

The **laguerreA** function returns the associated Laguerre polynomial of degree *n* (positive integer), index *k* (non-negative integer) and argument *x*. The associated Laguerre polynomials are defined by

$$L_n^k(x) = (-1)^k \frac{d^k}{dx^k} [L_{n+k}(x)] \text{ where } L_{n+k}(x) \text{ is the Laguerre polynomial.}$$

See Also

The **laguerre** and **laguerreGauss** functions.

References

Arfken, G., *Mathematical Methods for Physicists*, Academic Press, New York, 1985.

laguerreGauss

laguerreGauss(*p*, *m*, *r*)

The laguerreGauss function returns the normalized product of the associated Laguerre polynomials and a Gaussian. This function is typically encountered in solutions to physical problems where it represents the radial solution with an additional factor $\exp(i*m*\phi)$ which is not included in this case. The LaguerreGauss is given by

$$U_{pm}(r) = \left[\frac{2p!}{\pi(m+p)!} \right]^{1/2} (\sqrt{2}r)^m L_p^m(2r^2) \exp(-r^2)$$

See Also

The laguerre, laguerreA, and hermiteGauss functions.

Layout

Layout [*flags*] [*objectSpec* [, *objectSpec*]...][*as titleStr*]

The Layout operation creates a page layout.

Note: The Layout operation is antiquated and can not be used in user-defined functions. For new programming, use the **NewLayout** operation instead.

Parameters

All of the parameters are optional.

Each *objectSpec* parameter identifies a graph, table, textbox or picture to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See **Details**.

titleStr is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

Flags

/A=(rows,cols)	Specifies rows and columns for tiling or stacking.
/B=(r,g,b)	Specifies the background color for the layout. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Defaults to white (65535,65535, 65535).
/C=colorOnScreen	Obsolete. Prior to Igor Pro 5, this flag switched the screen display of the layout between black and white and color. Now layouts are always displayed in color. This flag has no effect but is still accepted.
/G=g	Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.
/HIDE=h	Shows (<i>h</i> = 1; default) or hides (<i>h</i> = 0) the window.
/I	Specifies that coordinates are in inches. This affects subsequent /G, /W, and <i>objectSpec</i> coordinates. Coordinates are relative to the top/left corner of the paper.
/K=k	Specifies window behavior when closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Clicking the close button kills the layout with no dialog. <i>k</i> =2: Clicking the close button doesn't do anything.
/M	Specifies that coordinates are in centimeters. This affects subsequent /G, /W, and <i>objectSpec</i> coordinates. Coordinates are relative to the top/left corner of the paper.
/P=orientation	<i>orientation</i> is either Portrait or Landscape (e.g., Layout /P= Landscape). This controls the orientation of the page in the layout. See Details . If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.
/R	Specifies that coordinates are in percent. This affects subsequent /G, /W, and <i>objectSpec</i> coordinates. For /W, coordinates are as a percent of the main screen. For /G and <i>objectSpec</i> , coordinates are relative to the top/left corner of the printing part of the page.
/S	Stacks objects.
/T	Tiles objects.

/W=(left, top, right, bottom)

Gives the layout window a specific location and size on the screen. Coordinates for */W* are in points unless */I* or */M* are specified.

Details

The orientation of the page is controlled by the page setup record associated with the layout. When you create a brand new layout window, the page setup record comes from your preferred page setup (which you specify via the Capture Layout Prefs dialog) or from a default page setup that Igor creates by calling the current printer driver. When you recreate a layout window using a Window macro, Igor reuses the page setup originally used for the layout window.

If you use the */P* flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as */T* and */G*.

The form of an *objectSpec* is:

***objectName* [(*objLeft*, *objTop*, *objRight*, *objBottom*)] [*/O=objType*][*/F=frame*]
[*/T=trans*][*/D=fidelity*]**

objectName can be the name of an existing graph, table or picture. It can also be the name of an object that does not yet exist. In this case it is called a “dummy object”.

objectSpec can be specified using a string by using the \$ operator, but the entire *objectSpec* must be in the string.

Here are some examples of valid usage:

```
Layout Graph0
Layout/I Graph0(1, 1, 6, 5)/F=1
String s = "Graph0"
Layout/I $s
String s = "Graph0(1, 1, 6, 5)/F=1"
Layout/I $s           // Entire object spec is in string.
```

The object’s coordinates are determined as follows:

- If *objectName* is followed by a coordinates specification in (*objLeft*, *objTop*, *objRight*, *objBottom*) form then this sets the object’s coordinates. The units for the coordinates are points unless the */I* or */M* flag was present in which case the units are inches or centimeters respectively.
- If the object coordinates are not specified explicitly but the Layout/*S* flag was present then the object is stacked. If the Layout/*T* flag was present then the object is tiled, and if the Layout/*A=(rows,cols)* flag is present, tiling is performed using that number of rows and columns.
- If the object’s coordinates are not determined by these rules then the object is set to a default size and is stacked.

Each object has a type (graph, table, textbox or picture) determined as follows:

If the *objectName* */O=objType* flag is present then it determines the object’s type:

```
/O=objType      objType=1: Graph.
                  objType=2: Table.
                  objType=8: Picture.
                  objType=32: Textbox.
```

If there is no */O* flag and *objectName* is the name of an existing graph, table or picture, then the object type is graph, table or picture.

If the object’s type is not determined by the above rules and *objectName* contains “Table”, “PICT”, or “TextBox”, then the object type is table, picture or textbox.

If the object’s type is not specified by any of the above rules, it is taken to be a graph type object.

The remaining flags have the following meanings:

```
/D=fidelity      fidelity=0: Low fidelity display.
                  fidelity=1: High fidelity display (default).
/F=frame         frame=0: No frame.
                  frame=1: Single frame (default).
                  frame=2: Double frame.
                  frame=3: Triple frame.
```

frame=4: Shadow frame.

/T=trans *trans=0*: Opaque (default).

trans=1: Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. Pictures may have been created transparent or opaque, and Igor cannot make an inherently opaque picture transparent.

See Also

The **NewLayout** and **LayoutInfo** operations. See Chapter II-16, **Page Layouts**.

Layout

Layout

Layout is a procedure subtype keyword that identifies a macro as being a page layout recreation macro. It is automatically used when Igor creates a window recreation macro for a layout. See **Procedure Subtypes** on page IV-149 and **Killing and Recreating a Layout** on page II-347 for details.

See Also

See Chapter II-16, **Page Layouts**.

LayoutInfo

LayoutInfo(*winNameStr*, *itemNameStr*)

The LayoutInfo function returns a string containing a semicolon-separated list of keywords and values that describe an object in a page layout or overall properties of the page layout. The main purpose of LayoutInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges objects.

winNameStr is the name of an existing page layout window or " " to refer to the top layout.

itemNameStr is a string expression containing one of the following:

1. The name (e.g., "Graph0") of a layout object to get information about that object.
2. An object instance (e.g., "Graph0#0" or "Graph0#1") to get information about a particular instance of an object. This is of use only in the unusual situation when the same object appears in the layout multiple times. "Graph0#0" is equivalent to "Graph0". "Graph0#1" is the second occurrence of Graph0 in the layout.
3. An integer object index starting from zero to get information about an object referenced by its position in the layout. Zero refers to the first object going from back to front in the layout.
4. The word "Layout" to get overall information about the layout.

Details

In cases 1, 2 and 3 above, where *itemNameStr* references an object, the returned string contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
FIDELITY	Object fidelity expressed as a code usable in a ModifyLayout fidelity command.
FRAME	Object frame expressed as a code usable in a ModifyLayout frame command.
HEIGHT	Object height in points.
INDEX	Object position in the back-to-front order of the layout, starting from zero.
LEFT	Object left position in points.
NAME	The name of the object.
SELECTED	Zero if the object is not selected or nonzero if it is selected. You can identify the first-selected object by examining the SELECTED code of all objects. The one with the smallest nonzero selected code is the object that was first selected.
TOP	Object top position in points.

Keyword	Information Following Keyword
TRANS	Object transparency expressed as a code usable in a ModifyLayout trans command.
TYPE	Object type which is one of: Graph, Table, Picture, or Textbox.
WIDTH	Object width in points.

In case 4 above, where *itemNameStr* is "Layout", the returned string contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
BGRGB	Layout background color expressed as <red>, <green>, <blue> where each color is a value from 0 to 65535.
MAG	Layout magnification: 0.25, 0.5, 1.0, or 2.0.
NUMOBJECTS	Total number of objects in the layout.
NUMSELECTED	Number of selected objects.
PAGE	A rectangle defining the part of the paper that is inside the margins, expressed in points. The format is <left>, <top>, <right>, <bottom>.
PAPER	A rectangle defining the bounds of the paper, expressed in points. The format is <left>, <top>, <right>, <bottom>.
SELECTED	A comma-separated list of the names of selected objects.
UNITS	Units used to display object locations and sizes. This will be one of the following: 0 for points, 1 for inches, 2 for centimeters.

LayoutInfo returns "" in the following situations:

winNameStr is "" and there are no layout windows.

winNameStr is a name but there are no layout windows with that name.

itemNameStr is not "Layout" and is not the name or index of an existing object.

Examples

This example sets the background color of all selected graphs in a particular page layout to the color specified by red, green, and blue, which are numbers from 0 to 65535.

```
Function SetLayoutGraphsBackgroundColor(layoutName,red,green,blue)
    String layoutName      // Name of layout or "" for top layout.
    Variable red, green, blue
    Variable index
    String info
    Variable selected
    String indexStr
    String objectTypeStr
    String graphNameStr
    index = 0
    do
        sprintf indexStr, "%d", index
        info = LayoutInfo(layoutName, indexStr)
        if (strlen(info) == 0)
            break      // No more objects
        endif
        selected = NumberByKey("SELECTED", info)
        if (selected)
            objectTypeStr = StringByKey("TYPE", info)
            if (CmpStr(objectTypeStr,"Graph") == 0)// This is a graph?
                graphNameStr = StringByKey("NAME", info)
                ModifyGraph/W=$graphNameStr wbRGB=(red,green,blue)
                ModifyGraph/W=$graphNameStr gbRGB=(red,green,blue)
            endif
        endif
    endif
```

```
        index += 1
    while(1)
End
```

See Also

The **Layout** operation. See Chapter II-16, **Page Layouts**.

LayoutMarquee

LayoutMarquee

LayoutMarquee is a procedure subtype keyword that puts the name of the procedure in the layout Marquee menu. See **Marquee Menu as Input Device** on page IV-115 for details.

See Also

See Chapter II-16, **Page Layouts**.

LayoutStyle

LayoutStyle

LayoutStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Layout dialog and in the Layout Macros menu. See **Layout Style Macros** on page II-366 for details.

See Also

See Chapter II-16, **Page Layouts** and **Layout Style Macros** on page II-366.

leftx

leftx (waveName)

The leftx function returns the X value of point 0 (the first point) of the named 1D wave. The leftx function is not multidimensional aware. The multidimensional equivalent of this function is **DimOffset**.

Details

Point 0 contains a wave's *first* value, which is usually the leftmost point when displayed in a graph. Leftx returns the value elsewhere called *x0*. The function DimOffset returns any of x0, y0, z0, or t0, for dimensions 0, 1, 2, or 3.

See Also

The **deltax** and **rightx** functions.

For multidimensional waves, see **DimDelta**, **DimOffset**, and **DimSize**.

For an explanation of waves and X scaling, see **Changing Dimension and Data Scaling** on page II-70.

Legend

Legend [flags] [legendStr]

The Legend operation puts a legend on a graph or page layout.

Parameters

legendStr contains the text that is printed in the legend.

If *legendStr* is missing or is the null string (""), the text needed for a default legend is automatically generated. Legends are automatically updated when waves are appended to or removed from the graph or when you rename a wave in the graph.

Flags

/H=*legendSymbolWidth*

Sets the width in points of the area in which to draw the wave symbols. A value of 0 means "default". This results in a width that is based on the text size in effect when the symbol is drawn. A value of 36 gives a 0.5 inch (36 points) width which is nice in most cases.

/H={*legendSymbolWidth*, *minThickness*, *maxThickness*}

A newer form (Igor Pro 4.0) of the /H flag. The *legendSymbolWidth* parameter works the same as described above.

The *minThickness* and *maxThickness* parameters allow you to create a legend whose line and marker thicknesses are different from the thicknesses of the associated traces in the

legendreA

graph. This can be handy to make the legend more readable when you use very thin lines or markers for the traces.

minThickness and *maxThickness* are values from 0.0 to 10.0. Also, setting *minThickness* to 0.0 and *maxThickness* to 0.0 (default) uses the same thicknesses for the legend symbols as for the traces.

/J Disables the default legend mechanism so that a default legend is not created even if string is the null string (" ") or omitted.

Window recreation macros use */J* in case *legendStr* is too long to fit on the same command line as the Legend operation itself. In this case, an AppendText command appears after the Legend command to append *legendStr* to the empty legend. For really long values of *legendStr*, there may be multiple AppendText commands.

/M[=sameSize] */M* or */M=1* specifies that legend markers should be the same size as the marker in the graph.

/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

For all other flags:

<i>/A=anchorCode</i>	<i>/C</i>	<i>/E[=exterior]</i>	<i>/F=frame</i>	<i>/K</i>
<i>/N=name</i>	<i>/R=newName</i>	<i>/S=style</i>	<i>/T=tabSpec</i>	<i>/V=vis</i>
<i>/W=winName</i>	<i>/X=xoffset</i>	<i>/Y=yoffset</i>		

see the **TextBox** and **AppendText** operations. Also see **ColorScale** and **Tag**.

Examples

The command **Legend** (with no parameters) creates a default legend. A default legend in a layout contains a line for each wave in each of the graphs in the layout, starting from the bottom graph and working toward the front.

The command:

```
Legend/C/N=name " "
```

changes the named existing legend to a default legend.

You can put a legend in a page layout with a command such as:

```
Legend "\s(Graph0.wave0) this is wave0"
```

This creates a legend in the layout that shows the symbol for wave0 in Graph0. The graph named in the command is usually in the layout but it doesn't have to be.

See Also

The **TextBox** operation for an explanation of the flags and the text content of *legendStr*.

legendreA

legendreA(*n*, *m*, *x*)

The legendreA function returns the associated Legendre polynomial: $P_n^m(x)$ where *n* and *m* are integers such that $0 \leq m \leq n$ and $|x| \leq 1$.

References

Arfken, G., *Mathematical Methods for Physicists*, Academic Press, New York, 1985.

limit

limit(*num*, *low*, *high*)

The limit function returns *num*, limited to the range from *low* to *high*:

num if $low \leq num \leq high$.

low if $num < low$.

high if $num > high$.

See Also

SelectNumber function.

LinearFeedbackShiftRegister

LinearFeedbackShiftRegister [*flags*]

The LinearFeedbackShiftRegister operation implements a, well, linear feedback shift register, or LFSR. A LFSR is a way to produce a sequence of very bad pseudorandom numbers, or a random bit stream (that is, a random sequence of zeroes or ones that over time are nearly equal in number).

If it produces bad random numbers, why would I want to use a LFSR? A properly-configured LFSR will create a “maximal-length sequence”: a LFSR of N bits will produce $2^N - 1$ numbers in a quasi-random sequence without repeating. That is, it will produce all the N -bit numbers except zero. This gives the sequence good spectral properties for certain applications, and, taking the least-significant bit as the output, it creates a pseudorandom bit stream with nearly equal numbers of zeroes and ones (*nearly* means one more one than zeroes).

The LinearFeedbackShiftRegister operation generates either a wave full of the sequential states of the shift register or a wave full of ones and zeroes representing the least significant bit of the shift register.

Linear Feedback Shift Registers

A LFSR is a shift register with taps. The tap bits are XOR’ed together and the result, after the register is shifted, becomes the new most significant bit. Here is a diagram of a 7-bit LFSR:

Each successive number is generated by shifting the contents of the register (boxes 1-7) to the right, while shifting in the output of the XOR node. The XOR node samples specified bits of the register contents, generating its output ready to be shifted in. Thus, the inputs of the XOR are bits sampled *before* a shift; the output of the XOR becomes the leading bit in the register *after* a shift.

In many applications the output of interest is the stream of bits that appear in the last position. This stream of bits is a pseudorandom sequence of ones and zeroes (or ones and minus ones, or whatever other binary sequence you need).

The bits fed into the XOR node are referred to as *taps*. The taps illustrated here would be specified with the tap list 7,6,4,1. As implemented in Igor Pro, the output tap (tap 7 in the illustration) is the least significant bit, so an alternate way to express the tap list is as the binary number 1001011_2 (77_{10}).

With the right taps, a LFSR produces a maximal-length sequence. The list of sequential states in a maximal-length sequence has length $2^N - 1$ without repeating a state. That means that every possible N -bit nonzero number appears exactly once in the maximal-length sequence.

Maximal-length tap lists always have an even number of taps.

If you have a tap list that gives a maximal-length sequence, you can generate another tap list from it. If your tap list is (n, A, B, C) the new tap list is (n, n-C, n-B, n-A). This new tap list will generate a bit stream that is the mirror image in time of the bit stream produced by the first tap list.

Flags

/DEST=wavename Specifies a wave to receive the generated sequence. With */MODE=0*, the number type of the wave must have at least *nbits* bits for an integer wave, or at least an *nbit* mantissa if it is a floating-point wave. That is, */N=25* requires a double-precision wave or a 32-bit integer wave. */N=18* requires any floating-point wave or a 16- or 32-bit integer wave. If you use an integer wave, we recommend an unsigned integer wave for */N=8, 16, or 32*. If */MODE=1* is used, any number type is acceptable. See the Details for what happens if you don’t use */DEST*.

/INIT=initialValue Sets the initial value of the shift register to *initialValue*. This will also be the first value in the output for */MODE=0*, or the least-significant bit of *initialValue* will be the first output for */MODE=1*. You can use this initial value to restart a very long sequence from the last state of a previous run.

Default is a single 1 bit in the first position (bit *nbits-1* for */N=nbits*).

/LEN= <i>length</i>	Sets the length of sequence to generate. If the sequence repeats before <i>length</i> states are generated, the sequence is terminated early. If <i>length</i> is larger than the number of states in a maximal-length sequence, you will get a maximal-length sequence, or a shorter sequence if the initial value is seen again (that is, your sequence is not a maximal-length sequence). You can specify <i>length</i> greater than the maximal-length sequence length, but it will be truncated to the maximal length.
/MAX= <i>index</i>	An internal table of tap lists gives maximal-length sequences. This table has up to 32 tap lists for each value of <i>nbits</i> . You select a tap list by setting <i>index</i> to a number from 0 to 31. For values of <i>nbits</i> that do not have 32 maximal-length tap lists, the table repeats. Most <i>nbits</i> values have many more than 32 possible maximal-length sequences. For each tap list in the table, another tap list can be accessed using the /MROR flag.
/MODE= <i>doBitStream</i>	Sets the output stream format. <i>doBitStream</i> =0: Succession of bit register states (default). <i>doBitStream</i> =1: Stream of ones and zeroes.
/MROR [=doMirror]	Transforms the tap list into its complementary tap list, creating a mirror-image bit stream, when you use /MROR or <i>doMirror</i> =1. Specify the tap list using /TAPS, /TAPB, or /MAX.
/N= <i>nbits</i>	Determines the number of bits in the shift register. A maximal-length sequence will have $2^{nbits}-1$ states. <i>nbits</i> must be in the range of 1-32. Note that <i>nbits</i> = 1 or 2 is not very interesting.
/STOP= <i>stopValue</i>	Terminates the sequence when <i>stopValue</i> is the next shift register value. You can use this flag to generate long sequences using multiple calls to LinearFeedbackShiftRegister by storing the initial value of the first call, and setting <i>stopValue</i> to that initial value in subsequent calls.
/TAPB= <i>tapbits</i>	An alternate way to express the tap list. <i>tapbits</i> is a number in which each bit represents a tap, with bit 0 representing the tap with tap number <i>nbits</i> .
/TAPS={ <i>t1</i> , <i>t2</i> , ...}	Specifies the tap list. Tap numbers are in the range from 1 to <i>nbits</i> .

Details

If the /TAPS, /TAPB, or /MAX flags are absent, the maximal-length sequence corresponding to /MAX=0 is generated.

In you omit the /DEST flag, a wave named W_LFSR will be generated for you. W_LFSR is an unsigned integer wave with number type set to the minimum size for the shift register size and /MODE setting. Thus, if you set /N=10/MODE=0, W_LFSR will be an unsigned 16-bit integer wave.

Because W_LFSR is an unsigned integer wave, you will need to redimension the wave to a floating-point wave for many purposes. Use the **Redimension** operation or the Redimension Waves item in the Data menu.

Up to /N=18, W_LFSR will initially be created large enough to hold a maximal-length sequence, unless you request a shorter sequence using the /LEN flag. If the initial value is seen again before a maximal-length sequence is generated, it means that the tap list specified was not one that generates a maximal-length sequence, and generation is terminated. The wave is shortened to the generated sequence length.

If you set a register size greater than /N=18 and you do not use /LEN, the generated sequence will stop after $2^{18}-1$ (262143) states. Note that beyond some N, it will be impossible to create a wave large enough to hold a maximal-length sequence.

Some tap lists do not generate maximal-length sequences but also do not repeat the initial value. In that case, the generated sequence will be of maximal length but will contain repeated subsequences. The V_flag variable will be set to 0 if the sequence was not a maximal-length sequence, or 1 if it was. If /LEN=*length* values were generated, V_flag is set to 2.

If you specify your own wave using /DEST, the sequence length will be the same as the length of your wave. Your wave will be resized if a shorter sequence is generated.

Generating Long Sequences in Smaller Segments

Very long maximal-length sequences will not fit in the largest wave you can make. It may also be more convenient to make multiple, small fragments of a longer sequence. You can do this using the /INIT, /STOP, and /LEN flags, along with the V_nextValue variable. Here is an example of making 1000-point subsequences from a 16-bit maximal-length sequence:

```
// Start with the first 1000 states, with initial value of 1
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=1
// Restart using the V_nextValue variable to continue the sequence
// /STOP=1 sets the stopping value to the first initial value
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
// Continue...
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
```

Variables

The LinearFeedbackShiftRegister operation returns information in the following variables:

V_flag	Set to zero when a nonmaximal-length sequence was detected. This occurs if the initial value is seen again before a maximal-length sequence was generated, or if a maximal-length sequence was generated but the final state was not the same as the initial state. Set to 1 when a maximal-length sequence was generated. Set to 2 when the sequence was limited by /LEN=length or by the default limit of $2^{18}-1$ (262143) states.
V_tapValue	Set to the binary representation of the tap sequence used. That is, you can generate the same sequence using /TAPB=V_tapValue. If you use /MROR=1, V_tapValue reflects that setting. It will also give the actual tap value used when you specify the a maximal-length sequence using the /MAX flag.
V_nextValue	Set to the next value beyond the last generated register state. This can be used to restart a truncated sequence.

Examples

Generate a 16-bit maximal-length sequence and reprocess the output values to be centered on zero and normalized to a maximum value of 1:

```
LinearFeedbackShiftRegister/N=16
Redimension/D W_LFSR
W_LFSR -= 2^15
W_LFSR /= 2^15-1
```

Another way to do the same thing that avoids the Redimension operation, which could lead to fragmentation of memory:

```
Make/D/N=(2^16-1) LFSR_output
LinearFeedbackShiftRegister/N=16/DEST=LFSR_output
LFSR_output -= 2^15
LFSR_output /= 2^15-1
```

Make a bit stream with random +1 and -1 instead of 0 and 1:

```
LinearFeedbackShiftRegister/N=16/MODE=1
Redimension/B W_LFSR
W_LFSR = W_LFSR*2-1
```

If you really need random numbers, we provide high-quality RNG's that return random deviates from a number of distributions. See **noise**, **gnoise**, and others.

References

A discussion of LFSR's can be found in "Generation of Random Bits" (Section 7.4) in Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992. They refer to "primitive polynomials modulo 2" and do not use the name Linear Feedback Shift Register, but it is the same thing. We use an implementation equivalent to their Method I.

ListBox

ListBox [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The ListBox operation creates or modifies the named control that displays, in the target window, a list from which the user can select any number of items.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the ListBox control to be created or changed.

key is one of the following parameters:

appearance={ <i>kind</i> [, <i>platform</i>]}	<p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i> can be one of default, native, or os9.</p> <p><i>platform</i> can be one of Mac, Win, or All.</p> <p>See Button and DefaultGuiControls for more appearance details.</p>
col= <i>c</i>	Sets the left-most visible column (user scrolling will change this). The list is scrolled horizontally as far as possible. Sometimes this won't be far enough to actually make column <i>c</i> the first column, but it will at least be visible. Use <i>c</i> =1 to put the left edge of column 1 (the <i>second</i> column) at the left edge of the list.
colorWave= <i>cw</i>	Specifies a 3 column numeric wave containing red, green, and blue values as short unsigned integers. Used in conjunction with planes in selWave to define foreground and background colors for individual cells. Values range from 65535 (full on) to 0.
disable= <i>d</i>	<p>Sets user editability of the control.</p> <p><i>d</i>=0: Normal.</p> <p><i>d</i>=1: Hide.</p> <p><i>d</i>=2: Draw in gray state; disable control action.</p>
editStyle= <i>e</i>	<p>Sets the style for cells designated as editable (see selWave, bit 1).</p> <p><i>e</i>=0: Uses a light blue background (default).</p> <p><i>e</i>=1: Draws a frame around the cell with a white background.</p> <p><i>e</i>=2: Combines the frame with the blue background. The background in all cases can be overridden using the colorWave parameter.</p>
font=" <i>fontName</i> "	Sets the font used for the list box items, e.g., font="Helvetica".
frame= <i>f</i>	<p>Specifies the list box frame style.</p> <p><i>f</i>=0: No frame.</p> <p><i>f</i>=1: Simple rectangle.</p> <p><i>f</i>=2: 3D well.</p> <p><i>f</i>=3: 3D raised.</p> <p><i>f</i>=4: text well style.</p>
fsize= <i>s</i>	Sets list box font size.
fstyle= <i>fs</i>	<p><i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows:</p> <p>bit 0: Bold.</p> <p>bit 1: Italic.</p> <p>bit 2: Underline.</p> <p>bit 3: Outline (<i>Macintosh only</i>).</p> <p>bit 4: Shadow (<i>Macintosh only</i>).</p> <p>See Setting Bit Parameters on page IV-11 for details about bit settings.</p>
hScroll= <i>h</i>	<p>Scrolls the list to the right by <i>h</i> pixels (user scrolling will change this). <i>h</i> is the total amount of horizontal scrolling, not an increment from the current scroll position: <i>h</i> will be the value returned in the V_horizScroll variable by ControlInfo.</p> <p>The hScroll value will not be automatically included in a ListBox recreation macro until Igor Pro 6 or later (to keep experiments compatible with Igor 5.0 and 5.01) unless you execute <code>SetIgorOption recreateListboxHScroll=1</code>. This means that normally the scroll position will be lost when saving a ListBox window recreation macro, and hScroll won't be included in the ControlInfo S_recreation string or in the WinRecreation result.</p>
keySelectCol= <i>col</i>	Sets scan column number <i>col</i> when doing keyboard selection. Default is to scan column zero.
listWave= <i>w</i>	A 1D or 2D text wave containing the list contents.
mode= <i>m</i>	<p>List selection mode specifying how many list selections can be made at a time.</p> <p><i>m</i>=0: No selection allowed.</p>

	<p>$m=1$: One or zero selection allowed.</p> <p>$m=2$: One and only one selection allowed.</p> <p>$m=3$: Multiple, but not disjoint, selections allowed.</p> <p>$m=4$: Multiple and disjoint selections allowed.</p> <p>When multiple columns are used, you can enable individual cells to be selected using modes 5, 6, 7, and 8 in analogy to $m=1-4$. When using $m=3$ or 4 with multiple columns, only the first column of the selWave is used to indicate selections. Checkboxes and editing mode, however, use all cells even in modes 0-4.</p> <p>Modes 9 and 10 are the same as modes 4 and 8 except they use different selection rules and require testing bit 3 as well as bit 0 in selWave. In modes 4 and 8, a shift click toggles individual cells or rows, but in modes 9 and 10, the Command (<i>Macintosh</i>) or Ctrl (<i>Windows</i>) key toggles individual cells or rows whereas Shift defines a rectangular selection. To determine if a cell is selected, perform a bitwise AND with 0x09.</p>
proc= <i>p</i>	Set name of user function proc to be called upon certain events. See discussion below.
pos={left,top}	Sets location of top left corner of the list box in pixels.
row= <i>r</i>	<i>r</i> is desired top row (user scrolling will change this). Use a value of -1 to scroll to the first selected cell (if any). Combine with selRow to select a row and to ensure it is visible (modes 1 and 2).
selCol= <i>c</i>	Defines the selected column when mode is 5 or 6 and no selWave is used. To read this value, use ControlInfo and the V_selCol variable.
selRow= <i>s</i>	Defines the selected row when mode is 1 or 2; when no selWave is used, it is defined by modes 5 or 6. Use -1 for no selection.
selWave= <i>sw</i>	<p>To read this value, use ControlInfo and the V_value variable.</p> <p><i>sw</i> is a numeric wave with the same dimensions as listWave. It is optional for modes 0-2, 5 and 6 and required in all other modes.</p> <p>In modes greater than 2, <i>sw</i> indicates which cells are selected. In modes 1 and 2 use ControlInfo to find out which row is selected.</p> <p>In all modes <i>sw</i> defines which cells are editable or function as checkboxes or disclosure controls.</p> <p>Numeric values are treated as integers with individual bits defined as follows:</p> <p>Bit 0 (0x01): Cell is selected.</p> <p>Bit 1 (0x02): Cell is editable.</p> <p>Bit 2 (0x04): Cell editing requires a double click.</p> <p>Bit 3 (0x08): Current shift selection.</p> <p>Bit 4 (0x10): Current state of a checkbox cell.</p> <p>Bit 5 (0x20): Cell is a checkbox.</p> <p>Bit 6 (0x40): Cell is a disclosure cell. Drawn as a disclosure triangle (<i>Macintosh</i>) or a treeview expansion node (<i>Windows</i>).</p> <p>In modes 3 and 4 bit 0 is set only in column zero of a multicolumn listbox.</p> <p>Other bits are reserved. Additional dimensions are used for color info. See the discussion for colorWave. As of Igor Pro 6, selWave is not required for modes 5 and 6.</p>
size={width,height}	Sets list box size in pixels.
special={kind,height,style}	<p>Specifies special cell formatting or contents.</p> <p><i>kind=0</i>: Normal text but with specified <i>height</i> (if nonzero). Use a <i>style</i> of 1 to autocalculate widths based on the entire list contents. In this case, user widths are taken to be minimums and the last is not repeated.</p> <p><i>kind=1</i>: Text taken to be the names of graphs. Images of the graphs are displayed in the cells. Use a <i>style</i> of 0 to display just the presentation portion of the graph or 1 to display it entirely.</p> <p><i>kind=2</i>: Text taken to be the names of pictures. Images are displayed in the cells.</p> <p><i>kind=3</i>: Displays a PNG, TIFF, or JPEG image. You can obtain binary picture data using SavePict.</p>

	For <i>kind</i> =1 or 2, <i>height</i> may be zero to auto-set cell height to same as width or a specific value.
<code>userColumnResize= u</code>	Enables resizing the list columns using the mouse. <i>u</i> =0: Columns are not resizable (default). The widths parameter still works, though. <i>u</i> =1: User can resize columns by dragging the column dividers. When resizing a column without Option, Alt, or Shift modifiers (a “normal” resizing), any width added to the column is subtracted from the following column (if any). When resizing while pressing Option (<i>Macintosh</i>) or Alt (<i>Windows</i>), only columns following the dragged divider will move (the same way table columns are resized). When pressing Shift, all columns are set to the same width as the column being resized. If the total widths of all columns is less than the width of the listbox, then each column expands to fill the available width.
<code>userdata=UDStr</code>	Sets the unnamed user data to <i>UDStr</i> .
<code>userdata(UDName)=UDStr</code>	Sets the named user data, <i>UDName</i> , to <i>UDStr</i> .
<code>userdata+=UDStr</code>	Appends <i>UDStr</i> to the current unnamed user data.
<code>userdata(UDName)+=UDStr</code>	Appends <i>UDStr</i> to the current named user data, <i>UDName</i> .
<code>widths={w1,w2,...}</code>	Optional list of minimum column widths in screen pixels. If more columns than widths, the last is repeated. If total of widths is greater than list box width then a horizontal scroll bar will appear. If total is less than available width then each expands proportionally.
<code>widths+={w1,w2,...}</code>	Additional column widths. Because only 400 characters fit on a command line, lists with many columns may require multiple widths+= parameters to define all the column widths. However if all the widths are the same, widths+= is not needed; just use: ListBox <i>ctrlName</i> widths={sameWidth}
<code>win=winName</code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

If the list wave has column dimension labels (see **SetDimLabel**), then those will be used as column titles. Note that a 1D wave is subtly different from a 1 column 2D wave. The former does not have any columns and therefore no column dimension labels.

You can make a column title bold using TextBox-style escape codes, provided the length, including formatting, is 31 characters or less:

```
SetDimLabel 1, columnNum, $"\\f01My Label", textWave
```

When using modes that allow multiple selections, use Shift to extend or add. Due to the use of Command on the Macintosh to bring up a pop-up menu, Command (*Macintosh*) and Ctrl (*Windows*) are not used.

You can specify individual cells as being editable by setting bit 1 (counting from zero on the right) in *selWave*. The user can start editing a cell by either clicking in it or, if the cell is selected, by pressing Enter (or Return). When finished, the user can press Enter to accept the changes or can press Escape to reject changes. The user may also press Up or Down Arrow to accept changes and begin editing the next editable cell in a column. Likewise, Tab and Shift-Tab moves to the next or previous column in a row. If bit 2 of *selWave* is set then a double click will be required rather than a single click. **Note:** in edit mode, Tab and Shift-Tab are used to move left and right because the Left and Right Arrow keys are used to move the text entry cursor left and right.

When the listbox has keyboard focus (either by tabbing to the list box or by clicking in the box), the keyboard arrow keys move a cell selection (or row depending on mode). When not in cell edit mode, Tab and Shift-Tab move the keyboard focus to other objects in the window. The Home, End, Page Up, and Page Down keys affect the vertical scroll bar.

When the listbox has focus, the user may type the first few chars of an entry in the list to select that entry. Only the first column is used. If a match is not found then nothing is done. The search is case insensitive.

You may define a user-function that will be called when certain events occur. Your action function must have the following syntax:

```
Function MyListboxProc(ctrlName,row,col,event) : ListboxControl
    String ctrlName      // name of this control
    Variable row         // row if click in interior, -1 if click in title
    Variable col         // column number
    Variable event       // event code
    ...
    return 0             // other return values reserved
End
```

The action procedure for a ListBox control can also use a predefined structure **WMListboxAction** as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a ListBox control, otherwise it will use the old-style method.

A ListBox action procedure using a structure has the format:

```
Function newActionProcName(LB_Struct) : ListboxControl
    STRUCT WMListboxAction &LB_Struct
    ...
End
```

For a ListBox control, the **WMListboxAction** structure has members as described in the following table:

WMListboxAction Structure Members

Member	Description
char ctrlName[MAX_OBJ_NAME+1]	Control name.
char win[MAX_WIN_PATH+1]	Host (sub)window.
STRUCT Rect winRect	Local coordinates of host window.
STRUCT Rect ctrlRect	Enclosing rectangle of the control.
STRUCT Point mouseLoc	Mouse location.
Int32 eventCode	Event that caused the procedure to execute. See table following for eventCode values.
String userdata	Primary (unnamed) user data. If this changes, it is written back automatically.
Int32 eventCode2	Used for the second event when two events happen at the same time. In this case, the various values in the structure refer to this second event. As of Igor 5.02, an event queue is used to deliver events to new-style action procedures and eventCode2 is not used. Instead your procedure simply gets called multiple times. See Event Queue on page V-305 for more details
Int32 eventMod	Bitfield of modifiers. See description of MODIFIERS: flags for SetWindow under Unnamed Hooks on page V-505.
Int32 row, col	Row number of selection in interior or -1 if in title area, and column number of selection.

WMListBoxAction Structure Members

Member	Description																					
	<p>The meanings of row and col are different for eventCodes 8-11:</p> <table><tr><th>Code</th><th>row</th><th>col</th></tr><tr><td>8</td><td>top visible row</td><td>horiz shift in pixels.</td></tr><tr><td>9</td><td>top visible row</td><td>horiz shift (user scroll).</td></tr><tr><td>9</td><td>-1</td><td>horiz shift (hScroll keyword).</td></tr><tr><td>10</td><td>top visible row</td><td>-1 (row keyword).</td></tr><tr><td>10</td><td>-1</td><td>first visible col (col keyword).</td></tr><tr><td>11</td><td>column shift</td><td>column resized by user.</td></tr></table> <p>If eventCode is 11, row is the horizontal shift in pixels of the column col that was resized, not the total horizontal shift of the list as reported in V_hORIZScroll by ControlInfo. If row is negative, the divider was moved to the left. col=0 corresponds to adjusting the divider on the right side of the first column. Use ControlInfo to get a list of all column widths.</p>	Code	row	col	8	top visible row	horiz shift in pixels.	9	top visible row	horiz shift (user scroll).	9	-1	horiz shift (hScroll keyword).	10	top visible row	-1 (row keyword).	10	-1	first visible col (col keyword).	11	column shift	column resized by user.
Code	row	col																				
8	top visible row	horiz shift in pixels.																				
9	top visible row	horiz shift (user scroll).																				
9	-1	horiz shift (hScroll keyword).																				
10	top visible row	-1 (row keyword).																				
10	-1	first visible col (col keyword).																				
11	column shift	column resized by user.																				
WAVE/T listWave	Reads back the same named input.																					
WAVE selWave	Reads back the same named input.																					
WAVE colorWave	Reads back the same named input.																					

The event code passed to your action procedure has the following meanings:

eventCode	Meaning
-1	Control being killed.
1	Mouse down.
2	Mouse up.
3	Double click.
4	Cell selection (mouse or arrow keys).
5	Cell selection plus Shift key.
6	Begin edit.
7	Finish edit.
8	Vertical scroll. See Scroll Event Warnings on page V-305.
9	Horizontal scroll by user or by the hScroll= <i>h</i> keyword.
10	Top row set by row= <i>r</i> or first column set by col= <i>c</i> keywords.
11	Column divider resized.

Action functions should respond only to documented eventCode values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

Some events cause another event immediately. For example a cell selection usually follows a mouse down. Before Igor Pro 5.02, the second event is stored in eventCode 2. In Igor Pro 5.02 and later, each event causes a separate call to your event handler. See **Event Queue** for more details.

The background and foreground (text) color of individual cells may be defined by providing colorWave in conjunction with specific planes in selWave. The planes in selWave are taken to be integer indexes into colorWave. The planes are defined by specific dimension labels and not by specific plane numbers. To provide foreground colors, define a plane labeled "foreColors" that contains the desired index values. Likewise define and fill a plane labeled "backColors" for background colors. The value 0 is special and indicates that the default colors should be used. Note that if you have a one column list for which you want to supply colors, the selWave needs to be three dimensional but with just one column. Here is an example:

```
Make/T/N=(5,1) tw= "row "+num2str(p)           // 5 row, 1 col text wave (2D)
Make/B/U/N=(5,1,2) sw           // 5 row, 1 col, 2 plane byte wave
Make/O/W/U myColors={{0,0,0},{65535,0,0},{0,65535,0},{0,0,65535},{0,65535,65535}}
MatrixTranspose myColors           // above was easier to enter as 3 rows, 5 cols
```

```
NewPanel
```

```
Listbox lb,mode=3,listWave= tw,selWave= sw,size={200,100},colorWave=myColors
sw[][][1]= p           // arbitrary index values into plane 1
```

Now, execute the following commands one at a time and observe the results:

```
SetDimLabel 2,1,backColors,sw           // define plane 1 as background colors
SetDimLabel 2,1,foreColors,sw           // redefine plane 1 s foreground colors
sw[][][%foreColors]= 4-p           // change the color index values
```

In the above example, the selWave was defined as unsigned byte. If you need more than 254 colors, you will have to use a larger number size.

Checkboxes in Cells

You can cause a cell to contain a checkbox by setting bit 5 in selWave. The title (if any) is taken from listWave and the results (selected / deselected) is bit 4 of selWave. If a checkbox cell is selected then the space bar will toggle the checkbox. (Clicking a checkbox cell does not select it — use the arrow keys.)

Errors

Your listbox may be drawn with a red X and an error code. The error codes are:

Error	Meaning
E1	Too small.
E2	listWave is invalid (missing, not text or no rows).
E3	listWave and selWave do not match in dimensions.
E4	mode > 2 with no selWave.

Event Queue

It is possible for a single user action to produce more than one event. For instance, using the Up Arrow key while editing to select a cell that is not visible will generate events 4, 8, and 6. As of Igor 5.02, such a cascade of events will generate three separate calls to your new-style action procedure that uses a structure for input. Before Igor 5.02 eventCode2 was used to deliver a second event to your action procedure (scroll events 8, 9, and 10 were not available then).

If your code tests for a nonzero value in eventCode2, and uses it only if it is nonzero, then the event queue method will not break your code. If you have determined empirically when you need to use eventCode2 and you do not test, your code will break.

If you really want to use the nonqueued style or if you encounter problems, you can use **SetIgorOption** to use the nonqueued method:

```
SetIgorOption useControlEventsQueue=0
```

Scroll Event Warnings

Events 8, 9, and 10 report to you that the listbox has been scrolled vertically or horizontally. These events are envisioned as allowing you to keep two listboxes synchronized (you may find other uses for these events). You might use an action procedure like this one to keep two listboxes (named list0 and list1) in sync:

```
Function ListBoxProc2(LB_Struct) : ListBoxControl
    STRUCT WMListboxAction &LB_Struct
    if (LB_Struct.eventCode == 8)
        String listname
        if (CmpStr(LB_Struct.ctrlName, "list1") == 0)
            listname = "list0"
```

ListMatch

```
        else
            listname = "list1"
        endif
        ControlInfo $listname
        if (V_startRow != LB_Struct.row)
            listbox $listname,row=LB_Struct.row
            ControlUpdate $listname
        endif
    endif
End
```

It is very easy to create an infinite cascade of events feeding back between the two listboxes, especially if you use event 10. When this happens, you will see your listboxes jiggling up and down endlessly. The test using ControlInfo is intended to make this unlikely.

The slow response of the old-style, nonstructure action procedure can defeat the ControlInfo test by delaying the action procedure execution. If you use events 8, 9, or 10, we recommended that you use the new-style action procedure.

Examples

Here is a simple Listbox example:

```
Make/O/T/N=30 tjack="this is row "+num2str(p)
Make/O/B/N=30 sjack=0
NewPanel /W=(19,61,319,261)
ListBox lb1,pos={42,9},size={137,94},listWave=tjack,selWave=sjack,mode= 3
Edit/W=(367,61,724,306) tjack,sjack
ModifyTable width(tjack)=148
```

Make selections in the list and note changes in the table and vice versa. Edit one of the list text values in the table and note update of the list.

An example experiment that lets you easily experiment with ListBox settings is available in “Examples:Testing & Misc:ListBox Demo.pxp”.

Setting Bit Parameters on page IV-11 for further details about bit settings.

The **GetUserData** operation for retrieving named user data.

ListMatch

ListMatch(listStr, matchStr [, listSepStr])

The ListMatch function returns each list item in *listStr* that matches *matchStr*.

ListStr should contain items separated by the *listSepStr* character, such as "abc;def;".

You may include asterisks in *matchStr* as a wildcard character. Note that matching is case-insensitive. See **stringmatch** for wildcard details.

ListSepStr is optional. If missing, it is taken to be ";".

See Also

The **GrepList**, **stringmatch**, **StringFromList**, and **WhichListItem** functions.

ln

ln(num)

The ln function returns the natural logarithm of *num*, -INF if *num* is 0, or NaN if *num* is less than 0. In complex expressions, *num* is complex, and ln(*num*) returns a complex value.

LoadData

LoadData [flags] fileOrFolderNameStr

The LoadData operation loads data from the named file or folder. “Data” means Igor waves, numeric and string variables and data folders containing them. The specified file or folder must be an Igor packed experiment file or a folder containing Igor binary data, such as an Igor unpacked experiment folder or a folder in which you have stored Igor binary wave files.

LoadData loads data objects into memory and they become part of the current Igor experiment, disassociated from the file from which they were loaded.

If loading from a file-system folder, the data (waves, variables, strings) in the folder, including any subfolders if /R is specified, is loaded into the current Igor data folder.

If loading from a packed Igor experiment file, the data in the file, including any packed subdata folders if /R is specified, is loaded into the current Igor data folder.

Use LoadData to load experiment data using Igor procedures. To load experiment data interactively, use the Data Browser (Data menu).

Parameters

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If *fileOrFolderNameStr* is omitted you get to locate the file (if /D is omitted) or the folder (if /D is present) via a dialog.

Flags

/D If present, loads from a file-system folder (a directory). If omitted, LoadData loads from an Igor packed experiment file.

/I Interactive. Forces LoadData to present a dialog.

/J=*objectNamesStr* Loads only the objects named in the semicolon-separated list of object names.

/L=*loadFlags* Controls what kind of data objects are loaded with a bit for each data type:

<i>loadFlags</i>	Bit Number	Loads this Object Type
1	0	Waves
2	1	Numeric Variables
4	2	String Variables

To load multiple data types, sum the values shown in the table. For example, /L=1 loads waves only, /L=2 loads numeric variables only, and /L=3 loads both waves and numeric variables. See **Setting Bit Parameters** on page IV-11 for further details about bit settings.

If no /L is specified, all object types are loaded. This is equivalent to /L=7. All other bits are reserved and should be set to zero.

/O[=*overwriteMode*] If /O alone is used, overwrites existing data objects in case of a name conflict. *overwriteMode* is defined as follows:

- 0: No overwrite, as if there were no /O.
- 1: Normal overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory. Incoming data folders completely replace any conflicting data folders in memory.
- 2: Mix-in overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory but nonconflicting objects in memory are left untouched.

See **Details** for more about overwriting.

/P=*pathName* Specifies folder to look in for the specified file or folder. *pathName* is the name of an existing symbolic path.

/Q Suppresses the normal messages in the history area.

/R Recursively loads subdata folders.

/S=*subDataFolderStr* Specifies a subdata folder within a packed experiment file to be loaded. See **Details** for more.

/T[=*topLevelName*] If /T=*topLevelName* is specified, it creates a new data folder in the current data folder with the specified name and places the loaded data in the new data folder. If just /T is specified, it creates a new data folder in the current data folder with a name derived from the name of the unpacked experiment folder, packed experiment file or packed subdata folder being loaded.

Details

If /T is present, LoadData loads the top level data folder and its contents. If /T is omitted, it loads just the contents of the top level data folder and not the data folder itself. This distinction has an analogy in the desktop. You can drag the contents of disk folder A into folder B or you can drag folder A itself into folder B.

If present, /S=*subDataFolderStr* specifies the subdata folder within the packed experiment file from which the load is to start. For example:

```
LoadData/P=Path1/S="Folder A:Folder B" "aPackedExpFile"
```

This starts loading from data folder "Folder B" which is in "Folder A" in the packed experiment file. Note that the string specified by /S must specify each subdata folder until the desired data folder is reached. Since this parameter is specified as a string, you must not use single quotes.

/S has no effect if you are loading from a file system folder rather than from a packed experiment file.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

If /J=*objectNamesStr* is used, then only the objects named in *objectNamesStr* are loaded into the current experiment. For example, /J="wave0;wave1" will load only the two named waves, ignoring any other data in the file or folder being loaded.

Assume that you have an experiment that contains 5 runs where each run, stored in a separate data folder in a packed experiment file, consists of data acquired from four channels from an ADC card. Using the /J flag, you can load just one specific channel from each run. This way you can compare that channel's data from all runs without loading the other channels.

The list of object names used with /J must be semicolon-separated. A semicolon after the last object name in the list is optional. Because the object names exist in a string expression, they should not be quoted. The list is limited to 1000 characters.

Using /J="" acts like no /J at all.

If you load a hierarchy of data folders (using the /R flag) with /J in effect, LoadData will create each data folder in the hierarchy even if it contains none of the named objects. This behavior is necessary to avoid loading a subdata folder without loading its parent, as well as other such complications.

If you do a load of a data folder, overwriting an existing data folder of the same name, the behavior of LoadData depends on whether you use /J. If you do not use /J, the entire data folder and all of its contents are replaced. If you do use /J, just the specified objects in the data folder are replaced, leaving any other preexisting objects in the data folder unchanged.

If you do not use the /O (overwrite) flag or if you use /O=0 and there is a conflict between objects or data folders in the current data folder and objects or data folders in the file or folder being loaded, LoadData will present a dialog to ask you if you want to replace the existing data. However, LoadData can not replace an object with an object of a different type and will refuse to do so.

You can overwrite an object that is in use, such as a wave that is displayed in a graph or table. You can also overwrite a data folder that contains objects that are in use. This is a powerful feature. Imagine that you define a data structure consisting of waves, variables and possibly subdata folders. You can display the data in graphs and tables and you can display these in a layout. You can then overwrite the data with an analogous data structure from a packed experiment file and Igor will automatically update any graphs, tables, or layouts that need to be updated.

Because LoadData can load from a complex packed Igor experiment file or from a complex hierarchy of file-system folders, it does not set the variables normally set by a file loader: S_path, S_fileName, S_waveNames and V_flag. To find what objects were created by LoadData, you can use the **CountObjects** and **GetIndexedObjName** functions.

The **SaveData** operation. Chapter II-9, **Importing and Exporting Data; Data Browser** on page II-114.

LoadPackagePreferences

```
LoadPackagePreferences [/MIS=mismatch /P=pathName] packageName, prefsFileName,  
recordID, prefsStruct
```

The LoadPackagePreferences operation loads preference data previously stored on disk by the **SavePackagePreferences** operation. The data is loaded into the specified structure.

If the /P flag is present then the location on disk of the preference file is determined by *pathName* and *prefsFileName*. However in the usual case the /P flag will be omitted and the preference file is located in a file named *prefsFileName* in a directory named *packageName* in the Packages directory in Igor's preferences directory.

Note: You must choose a very distinctive name for *packageName* as this is the only thing preventing collisions between your package and someone else's package.

See **Saving Package Preferences** on page IV-180 for background information and examples.

Parameters

packageName is the name of your package of Igor procedures. It is limited to 31 characters and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package.

prefsFileName is the name of a preference file to be loaded by LoadPackagePreferences. It should include an extension, typically ".bin".

prefsStruct is the structure into which data from disk, if it exists, will be loaded.

recordID is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordIDs* to identify which structure you want to load. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

Flags

<i>/MIS=mismatch</i>	Controls what happens if the number of bytes in the file does not match the size of the structure: 0: Returns an error. Default behavior if /MIS is omitted. 1: Returns the smaller of the size of the structure and the number of bytes in the file. Does not return an error. Use this if you want to read and update old versions of a preferences structure.
<i>/P=pathName</i>	Specifies the directory to look in for the file specified by <i>prefsFileName</i> . <i>pathName</i> is the name of an existing symbolic path. See Symbolic Paths on page II-30 for details. <i>/P=\$<empty string variable></i> acts as if the /P flag were omitted.

Details

LoadPackagePreferences sets the variable *V_flag* to 0 if no error occurred or to a nonzero error code. If the preference file does not exist, *V_flag* is set to zero so you must use *V_bytesRead* to detect that case.

LoadPackagePreferences sets the variable *V_bytesRead* to the number of bytes read from the file. This will be zero if the preference file does not exist.

After calling LoadPackagePreferences if *V_flag* is nonzero or *V_bytesRead* is zero then you need to create default preferences as illustrated by the example referenced below.

V_bytesRead, in conjunction with the /MIS flag, makes it possible to check for and deal with old versions of a preferences structure as it loads the version field (typically the first field) of an older or newer version structure. However in most cases it is sufficient to omit the /MIS flag and treat incompatible preference data the same as missing preference data.

Example

See the example under **Saving Package Preferences in a Special-Format Binary File** on page IV-181.

See Also

SavePackagePreferences.

LoadPICT

LoadPICT [*flags*] [*fileNameStr*][, *pictName*]

The LoadPICT operation loads a picture from a file or from the Clipboard into Igor. Once you have loaded a picture, you can append it to graphs and page layouts.

Parameters

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder

associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

If *fileNameStr* is "Clipboard" and */P=pathName* is omitted, LoadPICT loads its data from the Clipboard rather than from a file.

pictName is the name that you want to give to the newly loaded picture. You can refer to the picture by its name to append it to graphs and page layouts. LoadPICT generates an error if the name conflicts with some other type of object (e.g., wave or variable) or if the name conflicts with a built-in name (e.g., the name of an operation or function).

If you omit *pictName*, LoadPICT automatically names the picture as explained in **Details**.

Flags

<i>/I=resIndex</i>	Specifies the resource to load by resource index, starting from 1 (<i>Macintosh only</i>).
<i>/M=promptStr</i>	Specifies a prompt to use if LoadPICT needs to put up a dialog to find the file.
<i>/N=resNameStr</i>	A string that specifies the resource to load by resource name (<i>Macintosh only</i>).
<i>/O</i>	Overwrites an existing picture with the same name. If <i>/O</i> is omitted and there is an existing picture with the same name, LoadPICT displays a dialog in which you can resolve the name conflict.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/Q</i>	Quiet: suppresses the insertion of picture info into the history area.
<i>/R=resourceID</i>	Specifies the resource to load by resource ID (<i>Macintosh only</i>).
<i>/Z</i>	Doesn't load the picture, just checks for its existence.

Details

If the picture file is not fully specified then LoadPICT presents a dialog from which you can select the file. "Fully specified" means that LoadPICT can determine the name of the file (from the *fileNameStr* parameter) and the folder containing the file (from the flag */P=pathName* flag or from the *fileNameStr* parameter). If you want to force a dialog, omit the *fileNameStr* parameter.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

On Macintosh, LoadPICT can load picture data from the file's data or resource fork. Most graphics programs store a picture in the data fork. Some programs may store one or more pictures as resources. If you use */R*, */I*, or */N*, it loads the picture from the specified resource in the file. Otherwise, it loads the picture from the file's data fork.

If you omit *pictName*, LoadPICT automatically names the picture as follows:

On Macintosh, if the picture was loaded from the resource fork of a file (you used */R*, */I*, or */N*) and the resource had a nonempty name, it uses the resource name. If necessary, the name is made legal by replacing illegal characters or shortening it.

If the picture was loaded from a file, LoadPICT uses the file name. If necessary, it makes it into a legal name by replacing illegal characters or shortening it.

Otherwise, LoadPICT uses a name of the form "PICT_n".

If the resulting name is in conflict with an existing picture name, Igor puts up a name conflict resolution dialog.

LoadPICT sets the variable *V_flag* to 1 if the picture exists and fits in available memory or to 0 otherwise.

It also sets the string variable `S_info` to a semicolon-separated list of values:

Keyword	Information Following Keyword
NAME	Name of the loaded PICT, often "PICT_0", etc.
SOURCE	One of "data fork", "resource fork" or "Clipboard".
RESOURCENAME	Name of the resource the picture was loaded from, or " " if the source was not the file's resource fork.
RESOURCEID	Resource ID the picture was loaded from, or 0 if the source was not the file's resource fork.
TYPE	One of: "Enhanced metafile", "Windows metafile", "DIB", "Windows bitmap", "PICT", "PNG", or "Unknown type".
BYTES	Amount of memory used by the picture.
WIDTH	Width of the picture in pixels.
HEIGHT	Height of the picture in pixels.
PHYSWIDTH	Physical width of the picture in points.
PHYSHEIGHT	Physical height of the picture in points.

See Also

See **Pictures** on page III-405 for general information on how Igor handles pictures.

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTInfo** function.

LoadWave

LoadWave [*flags*] [*fileNameStr*]

The LoadWave operation loads data from the named Igor binary, Igor text, delimited text, fixed field text, or general text file into waves. LoadWave can load 1D and 2D data from delimited text, fixed field text and general text files, or data of any dimensionality from Igor binary and Igor text files.

Parameters

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If LoadWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If *fileNameStr* is "Clipboard" and */P=pathName* is omitted, LoadWave takes its data from the Clipboard rather than from a file. This is not implemented for binary loads.

If *fileNameStr* is omitted you get to locate the file via a dialog.

Flags

<i>/A</i>	"Auto-name and go" option (used with <i>/G</i> , <i>/F</i> or <i>/J</i>). This skips the dialog in which you normally enter wave names. Instead it automatically assigns names of the form <i>wave0</i> , <i>wave1</i> , choosing names that are not already in use. When used with <i>/W</i> , it reads wave names from the file instead of automatically assigning names and <i>/A</i> just skips the wave name dialog. The <i>/B</i> flag can also override names specified by <i>/A</i> .
<i>/A=baseName</i>	Same as <i>/A</i> but it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .
<i>/B=columnInfoStr</i>	Specifies the name, format, numeric type, and field width for columns in the file. See Specifying Characteristics of Individual Columns .
<i>/D</i>	Creates double precision waves. (Used with <i>/G</i> , <i>/F</i> or <i>/J</i> .) The <i>/B</i> flag can override the numeric precision specified by the <i>/D</i> flag.

<i>/E=editCmd</i>	<i>editCmd</i> = 1: Makes a new table containing the loaded waves. <i>editCmd</i> = 2: Appends the loaded waves to the top table. If no table exists, a new table is created. <i>editCmd</i> = 0: Same as if <i>/E</i> had not been specified (loaded waves are not put in any table).
<i>/F={numColumns, defaultFieldWidth, flags}</i>	Indicates that the file uses the fixed field file format. Most FORTRAN programs generate files in this format. <i>numColumns</i> is the number of columns of data in the file. <i>defaultFieldWidth</i> is the default number of characters in each column. If the columns do not all have the same number of characters, you need to use the <i>/B</i> flag to provide more information to LoadWave. <i>flags</i> is a bitwise parameter that controls the conversion of text to values. The bits are defined as follows: bit 0: If set, any field that consists entirely of the digit “9” is taken to be blank. A field that consists entirely of the digit “9” except for a leading “+” or “-” is also taken to be blank. All other bits are reserved and you should use 0 for them.
<i>/G</i>	Indicates that the file uses the general text format.
<i>/H</i>	Copies Igor Binary waves to “home”. See Avoiding Shared Igor Binary Files on page II-34.
<i>/J</i>	Indicates that the file uses the delimited text format.
<i>/K=k</i>	Controls how to determine whether a column in the file is numeric or text (only for delimited text and fixed field text files). <i>k</i> =0: Deduces the nature of the column automatically. <i>k</i> =1: Treats all columns as numeric. <i>k</i> =2: Treats all columns as text. This flag as well as the ability to load text data into text waves were added in Igor Pro 3.0. The default for the LoadWave operation is <i>/K</i> =1, meaning that it will treat all columns as numeric. We did this so that existing procedures would behave the same in Igor Pro 3.0 as before. Use <i>/K</i> =0 when you want to load text columns into text waves. <i>/K</i> =2 may have use in a text-processing application. For finer control, the <i>/B</i> flag specifies the format of each column in the file individually.
<i>/L={nameLine, firstLine, numLines, firstColumn, numColumns}</i>	Affects loading delimited text, fixed field text, and general text files only (<i>/J</i> , <i>/F</i> or <i>/G</i>). <i>/L</i> is accepted no matter what the load type but is ignored for Igor binary and Igor text loads. Line and column numbers start from 0. <i>nameLine</i> is the number of the line containing column names. For general text loads, 0 means auto. See Loading General Text Files on page II-136 for details. <i>firstLine</i> is the number of the first line to load into a wave. For general text loads, 0 means auto. See Loading General Text Files on page II-136 for details. <i>numLines</i> is the number of lines that should be treated as data. 0 means auto which loads until the end of the file or until the end of the block of data in general text files. The <i>numLines</i> parameter can also be used to make loading very large files more efficient. See Loading Very Large Files . <i>firstColumn</i> is the number of the first column to load into a wave. This is useful for skipping columns. <i>numColumns</i> is the number of columns to load into a wave. 0 means auto, which loads all columns.
<i>/M</i>	Loads data as matrix wave. If <i>/M</i> is used then it ignores the <i>/W</i> flag (read wave names) and follows the <i>/U</i> flags instead. The wave is autonamed unless you provide a specific wave name using the <i>/B</i> flag. The type of the wave (numeric or text) is determined by an assessment of the type of the first loaded column unless you override this using the <i>/K</i> flag or the <i>/B</i> flag.

See **The Load Waves Dialog for Delimited Text — 2D** on page II-132 for further information.

/N Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.

/N=baseName Same as /N except that it automatically assigns wave names of the form *baseName0*, *baseName1*.

/O Overwrite existing waves in case of a name conflict.

/P=pathName Specifies the folder to look in for *fileNameStr*. *pathName* is the name of an existing symbolic path.

/Q Suppresses the normal messages in the history area.

/R={languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, pivotYear} Specifies a custom date format for dates in the file. If the /R flag is used, it overrides the date setting that is part of the /V flag.

languageName controls the language used for the alphabetic date components, namely the month and the day-of-week. *languageName* is one of the following:

Default			
Chinese	ChineseSimplified	Danish	Dutch
English	Finnish	French	German
Italian	Japanese	Korean	Norwegian
Portuguese	Russian	Spanish	Swedish

Default means the system language on Macintosh or the user default language on Windows.

yearFormat is one of the following codes:

- 1: Two digit year.
- 2: Four digit year.

monthFormat is one of the following codes:

- 1: Numeric, no leading zero.
- 2: Numeric with leading zero.
- 3: Abbreviated alphabetic (e.g., Jan).
- 4: Full alphabetic (e.g., January).

dayOfMonthFormat is one of the following codes:

- 1: Numeric, no leading zero.
- 2: Numeric with leading zero.

dayOfWeekFormat is one of the following codes:

- 1: Abbreviated alphabetic (e.g., Mon).
- 2: Full alphabetic (e.g., Monday).

layoutStr describes which components appear in the date in what order and what separators are used. *layoutStr* is constructed as follows (but with no line break):

```
"<component keyword><separator>
<component keyword><separator>
<component keyword><separator>
<component keyword>"
```

where <component keyword> is one of the following:

Year

Month

DayOfMonth

DayOfWeek

Extraneous spaces are not allowed in *layoutStr*. Each separator must be no longer than 15 characters. No component can be used more than once. Some components may be used zero times.

pivotYear determines how LoadWave interprets two-digit years. If the year is specified using two digits, *yy*, and is less than *pivotYear* then the date is assumed to be 20*yy*. If the two digit year is greater than or equal *pivotYear* then the year is assumed to be 19*yy*. Because Igor supports dates from 1904 to 2040, *pivotYear* must be between 4 and 40.

See **Loading Custom Date Formats** for further discussion of date formats.

/T Indicates that the file uses the Igor text format.

/U={*readRowLabels*, *rowPositionAction*, *readColLabels*, *colPositionAction*}

These parameters affect loading a matrix (/M) from a delimited text (/J) or a fixed field text (/F) file. They are accepted no matter what the load type is but are ignored when they don't apply.

If *readRowLabels* is nonzero, it reads the first column of data in the file as the row labels for the matrix wave.

rowPositionAction has one of the following values:

- 0: The file has no row position column.
- 1: Uses the row position column to set the row scaling of the matrix wave.
- 2: Creates a 1D wave containing the values in the row position column. The name of the 1D wave will be the same as the matrix wave but with the suffix "_RP".

The *readColumnLabels* and *columnPositionAction* parameters have analogous meanings. The suffix used for the column position wave is "_CP".

See Chapter II-9, **Importing and Exporting Data** for further details.

/V={*delimsStr*, *skipCharsStr*, *numConversionFlags*, *loadFlags*}

These parameters affect loading delimited text (/J) and fixed field text (/F) data and column names. They are accepted no matter what the load type is but are ignored when they don't apply. These parameters should rarely be needed.

delimsStr is a string expression containing the characters that should act as delimiters for delimited file loads. The default is "\t," for tab and comma. You can specify the space character as a delimiter, but it is always given the lowest priority behind any other delimiters contained in *delimsStr*. The low priority means that if a line of text contains any other delimiter besides the space character, then that delimiter is used rather than the space character.

skipCharsStr is a string expression containing characters that should always be treated as garbage and skipped when they appear before a number. The default is "\$" for space and dollar sign. This parameter should rarely be needed.

numConversionFlags is a bitwise parameter that controls the conversion of text to numbers. The bits are defined as follows:

- bit 0 — if set: dates are dd/mm/yy;
if cleared: dates are mm/dd/yy.
- bit 1 — if set: decimal character is comma;
if cleared: it is period.

bit 2: If set: Enables pre-counting of lines of data. See **Loading Very Large Files**.

All other bits are reserved and you should use 0 for them. To set both bits use *numConversionFlags* = 3. If the /R flag is used to specify the date format, this overrides the setting of bit 0.

loadFlags is a bitwise parameter that controls the overall load. The bits are defined as follows:

- bit 0 — if set, ignores blanks at the end of a column. This is appropriate if the file contains columns of unequal length. Set *loadFlags* = 1 to set bit 0.
- bit 1 — if set, when the /W flag is specified and the line containing column labels starts with one or more space characters, the spaces are taken to be a blank column name. The resulting column will be named Blank. Use this if both the line containing column labels and the lines containing data start with leading spaces in a space-delimited file. Set *loadFlags* = 2 to set bit 1.

All other bits are reserved and you should use 0 for them.

/W Looks for wave names in a file. (With /G, /F, and /J.)

Use /W/A to read wave names from the file and then continue the load without displaying the normal wave name dialog.

Details

Without the /G, /F, /J, or /T flags, LoadWave loads Igor Binary files.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

When loading a general text file, the delimiters are always tab, comma and space.

Loading Custom Date Formats

Here are some examples showing custom date formats and how you would specify them using the /R flag:

Date Format	Specification
October 11, 1999	/R={English, 2, 4, 1, 1, "Month DayOfMonth, Year", 40}
Oct 11, 1999	/R={English, 2, 3, 1, 1, "Month DayOfMonth, Year", 40}
11 October 1999	/R={English, 2, 4, 1, 1, "DayOfMonth Month Year", 40}
11 Oct 1999	/R={English, 2, 3, 1, 1, "DayOfMonth Month Year", 40}
10/11/99	/R={English, 1, 2, 1, 1, "Month/DayOfMonth/Year", 40}
11-10-99	/R={English, 1, 2, 2, 1, "DayOfMonth-Month-Year", 40}
11-Jun-99	/R={English, 1, 3, 2, 1, "DayOfMonth-Month-Year", 40}
991011	/R={English, 1, 2, 2, 1, "YearMonthDayOfMonth", 40}
19991011	/R={English, 2, 2, 2, 1, "YearMonthDayOfMonth", 40}

When loading data as delimited text, if you use a date format containing a comma, such as "October 11, 1999", you must use the /V flag to make sure that LoadWave will not treat the comma as a delimiter.

When loading a date format that consists entirely of digits, such as 991011, you must use the LoadWave/B to specify that the data is a date. Otherwise, LoadWave will treat it as a regular number.

Loading Very Large Files

The number of waves (columns) or points (rows) that LoadWave can handle when loading a text file is limited only by available memory.

You can improve the speed and efficiency of loading very large files (i.e., more than 50,000 lines of data) using the *numLines* parameter of the /L flag. Normally this parameter is used to load a section of the file instead of the whole file. However, in delimited, general text and fixed field text loads, the *numLines* parameter also specifies how many rows the waves should initially have. Thus all of the required memory is allocated at the start of the load, rather than increasing the number of wave rows over and over as more lines of data are loaded. When loading very large files, if you know the exact number of lines of data in the file, use the *numLines* parameter of the /L flag. If you don't know the exact number of lines, you can provide a number that is guaranteed to be larger.

As of Igor Pro 6.02, if you omit the /L flag or if the *numLines* parameter is zero, and if you are loading a file greater than 500,000 bytes, and if you are running on Windows, LoadWave will automatically count the lines of data in the file so that the entire wave can be allocated before data loading starts. This acts as if you used /L and set *numLines* to the exact correct value. For very large files on Windows, this can speed the loading process considerably. For small files on Windows and for files of any size on Macintosh, it actually makes the load slower. That's why this feature takes effect only on Windows and only for files of greater than 500,000 bytes. You can disable this feature by using the /V flag and setting bit 2 to 1.

Generating Wave Names

The /N flag automatically names new waves "wave" (or *baseName* if =*baseName* is used) plus a digit. The digit starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The /A flag is like /N except that it skips names already in use.

Specifiying Characteristics of Individual Columns

The /B=*columnInfoStr* flag provides information to LoadWave for each column in a delimited text (/J), fixed field text (/F) or general text (/G) file. The flag overrides LoadWave's normal behavior. In most cases, you will not need to use it.

columnInfoStr is constructed as follows:

```
"<column info>;<column info>; ... ;<column info>;"
```

where <column info> consists of one or more of the following:

- | | |
|-------------|--|
| C=<number> | The number of columns controlled by this column info specification. <number> is an integer greater than or equal to one. |
| F=<format> | <p>A code that specifies the data type of the column or columns. <format> is an integer from -2 to 10. The meaning of the <format> is:</p> <ul style="list-style-type: none">-2: Text. The column will be loaded into a text wave.-1: Format unknown. It will deduce the format.0 to 5: Numeric.6: Date.7: Time.8: Date/Time.9: Octal number.10: Hexadecimal number. <p>The F= flag is used for delimited text and fixed field text files only. It is ignored for general text files.</p> |
| N=<name> | <p>A name to use for the column. <name> can be a standard name (e.g., wave0) or a quoted liberal name (e.g., 'Heart Rate'). If <name> is '_skip_' (including single quotation marks) then LoadWave will skip the column.</p> <p>The N= flag works for delimited text, fixed field text and general text files.</p> |
| T=<numtype> | <p>A number that specifies what the numeric type for the column should be. This flag overrides the LoadWave/D flag. It has no effect on columns whose format is text. <numtype> must be one of the following:</p> <ul style="list-style-type: none">2: 32-bit float.4: 64-bit float.8: 8-bit signed integer.16: 16-bit signed integer.32: 32-bit signed integer.72: 8-bit unsigned integer.80: 16-bit unsigned integer.96: 32-bit unsigned integer. |
| W=<width> | <p>The column field width for fixed field files. <width> is an integer greater than or equal to one. Fixed width files are FORTRAN-style files in which a fixed number of characters is allocated for each column and spaces are used as padding.</p> <p>The W= flag is used for fixed field text only.</p> |

Here is an example of the /B=*columnInfoStr* flag:

```
/B="C=1,F=-2,T=2,W=20,N=Factory; C=1,F=6,W=16,T=4,N=MfgDate;  
C=1,F=0,W=16,T=2,N=TotalUnits; C=1,F=0,W=16,T=2,N=DefectiveUnits;"
```

This example is shown on two lines but in a real command it would be on a single line. In a procedure, it could be written as:

```
String columnInfoStr = ""  
columnInfoStr += "C=1,F=-2,T=2,W=20,N=Factory;"  
columnInfoStr += "C=1,F=6,T=4,W=16,N=MfgDate;"  
columnInfoStr += "C=1,F=0,T=2,W=16,N=TotalUnits;"  
columnInfoStr += "C=1,F=0,T=2,W=16,N=DefectiveUnits;"
```

Note that each flag inside the quoted string ends with either a comma or a semicolon. The comma separates one flag from the next within a particular column info specification. The semicolon marks the end of a column info specification. The trailing semicolon is required. Spaces and tabs are permitted within the string.

This example provides information about a file containing four columns.

The first column info specification is `"C=1;F=-2,T=2,W=20,N=Factory;"`. This indicates that the specification applies to one column, that the column format is text, that the numeric format is single-precision floating point (but this has no effect on text columns), that the column data is in a fixed field width of 20 characters, and that the wave created for this column is to be named `Factory`.

The second column info specification is `"C=1;F=6,T=4,W=16,N=MfgDate;"`. This indicates that the specification applies to one column, that the column format is date, that the numeric format is double-precision floating point (double precision should always be used for dates), that the column data is in a fixed field width of 16 characters, and that the wave created for this column is to be named `MfgDate`.

The third column info specification is `"C=1;F=0,T=2,W=16,N=TotalUnits;"`. This indicates that the specification applies to one column, that the column format is numeric, that the numeric format is single-precision floating point, that the column data is in a fixed field width of 16 characters, and that the wave created for this column is to be named `TotalUnits`.

The fourth column info specification is the same as the third except that the wave name is `DefectiveUnits`.

All of the items in a column specification are optional. The default value for each item in the column info specification is as follows:

<code>C=<number></code>	<code>C=1</code> . Specifies that the column info describes one column.
<code>F=<format></code>	<code>F=-1</code> . Determines the format as dictated by the <code>/K</code> flag. If <code>/K=0</code> is used, LoadWave will automatically determine the column format.
<code>N=<name></code>	<code>N=_auto_</code> . Generates the wave name as it would if the <code>/B</code> flag were omitted.
<code>T=<numtype></code>	Defaults to <code>T=4</code> (double precision) if the LoadWave <code>/D</code> flag is used or to <code>T=2</code> (single precision) if the <code>/D</code> flag is omitted.
<code>W=<width></code>	<code>W=0</code> . For a fixed width file, LoadWave will use the default field width specified by the <code>/F</code> flag unless you provide an explicit field width greater than 0 using <code>W=<width></code> .

Taking advantage of the default values, we could abbreviate the example as follows:

```
/B="F=-2,W=20,N=Factory; F=6,T=4,W=16,N=MfgDate;
W=16,N=TotalUnits; W=16,N=DefectiveUnits;"
```

If the file were not a fixed field text file, we would omit the `W=` flag and the example would become:

```
/B="F=-2,N=Factory;F=6,T=4,N=MfgDate;N=TotalUnits;N=DefectiveUnits;"
```

Here are some more examples and discussion that illustrate the use of the `/B=columnInfoStr` flag.

In this example, the `/B` flag is used solely to specify the name to use for the waves created from the columns in the file:

```
/B="N=WaveLength; N=Absorbance;"
```

The wave names in the previous example are standard names. If you want to use liberal names, such as names containing spaces or dots, you must use single quotes. For example:

```
/B="N='Wave Number'; N='Reflection Angle';"
```

The name that you specify via `N=` can not be used if overwrite is off and there is already a wave with this name or if the name conflicts with a macro, function or operation or variable. In these cases, LoadWave generates a unique name by adding one or more digits to the name specified by the `N=` flag for the column in question. You can avoid the problem of a conflict with another wave name by using the overwrite (`/O`) flag or by loading your data into a newly-created data folder. You can minimize the likelihood of a name conflict with a function, operation or variable by avoiding vague names.

If you specify the same name in two `N=` flags, LoadWave will generate an error, so make sure that the names are unique.

Except if the specified name is `'_skip_'`, the `N=` flag generates a name for one column only, even if the `C=` flag is used to specify multiple columns. Consider this example:

```
/B="C=10,N=Test;"
```

This ostensibly uses the name `Test` for 10 columns. However, wave names must be unique, so LoadWave will not do this. It will use the name `Test` for just the first column and the other columns will receive default names.

Also, when loading data into a matrix wave, LoadWave uses only one name. If you specify more than one name, only the first is used.

In this example, the /B flag solely specifies the format of each column in the file. The file in question starts with a text column, followed by a date column, followed by 3 numeric columns.

```
/B="F=-2; F=6; C=3,F=0"
```

In most cases, it is not necessary to use the F= flag because LoadWave can automatically deduce the formats. The flag is useful for those cases where it deduces the column formats incorrectly. It is also useful to force LoadWave to interpret a column as octal or hexadecimal because LoadWave can not automatically deduce these formats.

The numeric codes (0...10) used by the F= flag are the same as the codes used by the ModifyTable operation. If you create a table using the /E flag, the F= flag controls the numeric format of table columns.

The code -1 is not a real column format code. If you use F=-1 for a particular column, LoadWave will deduce the format for that column from the column text.

In this example, the /B flag is used solely to specify the width of each column in a fixed field file. This file contains a 20 character column followed by ten 16 character columns followed by three 24 character columns.

```
/B="C=1,W=20; C=10,W=16; C=3,W=24"
```

The field widths specified via W= override the default field width specified by the /F flag. If all of the columns in the file have the same field width then you can use just the /F flag.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded.

Output Variables

LoadWave sets the following variables:

V_flag	Number of waves loaded.
S_fileName	Name of the file being loaded.
S_path	File system path to the folder containing the file.
S_waveNames	Semicolon-separated list of the names of loaded waves.

The setting of S_path was added in Igor Pro 3.14. S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon. If LoadWave is loading from the Clipboard, S_path is set to "".

When LoadWave presents an Open File dialog and the user cancels, V_flag is set to 0 and S_fileName is set to "".

The **ImageLoad** operation.

See Chapter II-9, **Importing and Exporting Data** for further information on loading waves, including loading multidimensional data from HDF, PICT, TIFF and other graphics files. Check the "More Extensions:File Loaders" folder other file-loader extensions.

Setting Bit Parameters on page IV-11 for further details about bit settings.

Loess

```
Loess [flags] srcWave = srcWaveName [, factors = factorWaveName1  
[, factorWaveName2 ...]]
```

The Loess operation smooths *srcWaveName* using locally-weighted regression smoothing. This algorithm is sometimes classified as a "nonparametric regression" procedure. The regression can be constant, linear, or quadratic. A robust option that ignores outliers is available. See **Basic Algorithm**, **Robust Algorithm**, and **References** for additional details and terminology.

This implementation works with waveforms, XY pairs of waves, false-color images, matrix surfaces, and multivariate data (one dependent data wave with multiple independent variable data waves).

Unlike the **FilterFIR** operation, Loess discards any NaN input values and will not generate a result that is wholly NaN.

Parameters

srcWaveName is the input data to be smoothed. It may be a one-dimensional or a two-dimensional wave, and it may contain NaNs.

When no /DEST flag is specified, Loess will overwrite *srcWaveName* with the smoothed result.

If *srcWaveName* is one-dimensional and no factors are provided, X values are derived from the X scaling of *srcWaveName*.

If *srcWaveName* is two-dimensional, the factors keyword is not permitted and the X and Y values are derived from the X and Y scaling of *srcWaveName*.

Higher dimensions of *srcWaveName* are not supported.

The optional factors parameter(s) provide the independent variable value(s) that correspond to the observed value in *srcWaveName*.

Note: Cleveland et al. (1992) use the term “multiple factors” instead of “multivariate”, hence the keyword name “factors” is used to denote these waves.

Use one factors wave when *srcWaveName* is the one-dimensional Y wave of an XY data pair:

```
srcWaveName[i] = someFunction( factorWaveName1[i] )
```

Use multiple factors waves when *srcWaveName* contains the values of a multivariate function.

“Multivariate” means that *srcWaveName* contains the observed results of a process that combines multiple independent input variables:

```
srcWaveName[i] = someFunction( factorWaveName1[i], factorWaveName2[i],... )
```

A maximum of 10 factors waves is supported.

All factors wave(s) must be numeric, noncomplex, one-dimensional and have the same number points as *srcWaveName*.

Any NaN values in *srcWaveName*[i], *factorWaveName1*[i], *factorWaveName2*[i], ... cause all corresponding values to be ignored. Factors waves may contain NaN values only when /DFCT is specified.

Loess does not support NaNs in any of *destFactorWaveName1*, *destFactorWaveName2*,... and the results are undefined.

Flags

/CONF={*confInt*, *ciPlusWaveName* [, *ciMinusWaveName*]}

confInt specifies the confidence interval (a probability value from 0 to 1).

ciPlusWaveName and the optional *ciMinusWaveName* are the names of new or overwritten output waves to hold the fitted value \pm the confidence interval.

Note: /CONF uses large memory allocations, approximately $N*N*8$ bytes, where N is the number of points in *srcWaveName* (see **Memory Details**).

/DEST=*destWaveName* Specifies the name of the wave to hold the smoothed data. It creates *destWaveName* if it does not already exist or overwrites it if it does. The X (and possibly Y) scaling of *destWave* determines the independent (factor) coordinates unless /DFCT is also specified.

/DFCT={*destFactorWaveName1* [, *destFactorWaveName2*...]}

Specifies the names of one-dimensional waves providing the independent coordinates at which to compute the smoothed data.

If /DFCT is used, the same number of waves must be specified for /DFCT and for factors = {*factorWaveName1* [, *factorWaveName2*...]}, though their lengths may (and usually will) be different. The length of *destFactorWaveName* waves must be the same as that of the *destWaveName* wave.

All destination factor waves must be numeric, noncomplex, and one-dimensional. The number of destination factor waves must match the number of source factor waves (if specified), or match the dimensionality of *srcWaveName* (one destination factor wave if *srcWaveName* is one-dimensional, two destination factors waves if *srcWaveName* is two-dimensional.)

The values in the destination factor waves may not be NaN.

/E=*extrapolate*

Set *extrapolate* to nonzero to use a slower fitting method that computes values beyond the domain defined by the source factors. This is the “surface” parameter named “direct” in Cleveland et al. (1992). The default is *extrapolate* = 0, which uses the “interpolate” surface parameter, instead.

/N=*neighbors*

Specifies the number of values in the smoothing window.

	<p>If <i>neighbors</i> is even, the next larger odd number is used. When <i>neighbors</i> is less than two, no smoothing is done.</p> <p>The default is $0.5 * \text{numpts}(\text{srcWaveName})$ rounded up to the next odd integer or 3, whichever is larger.</p> <p>Use either /N or /SMTH, but not both.</p>
/NORM [=norm]	<p>Set <i>norm</i> to 0 when specifying multiple factors and they all have the same scale and meaning, for example multiple factors all in units of meters.</p> <p>The default is <i>norm</i> = 1, which normalizes each factor independently when computing the weighting function. This is appropriate when the factors are not dimensionally related, for example one factor measures wavelength and another measures temperature.</p>
/ORD=order	<p>Specifies the regression (fitting) order, the <i>d</i> parameter in Cleveland (1977):</p> <p><i>order</i>=0: Fits a constant to the locally-weighted neighbors around each point.</p> <p><i>order</i>=1: Fits a line to the locally-weighted neighbors around each point (Lowess smoothing).</p> <p><i>order</i>=2: Default; fits a quadratic (Loess smoothing).</p>
/PASS=passes	<p>The number of iterations of local weighting and regression fitting performed. The minimum is 1 and the default is 4. In Cleveland (1977), <i>passes</i> corresponds to <i>r</i>.</p>
/R [=robust]	<p>Set <i>robust</i> to nonzero to use a robust fitting method that uses a bisquare weight function instead of the normal tricube weight function. This corresponds to the “symmetric” family in Cleveland et al. (1992). The robust method is less affected by outliers. The default is <i>robust</i> = 0, which is the “gaussian” family in Cleveland et al. (1992).</p>
/SMTH=sf	<p>Another way to express the number of values in the smoothing window, $0 \leq sf \leq 1$. The default is 0.5.</p> <p>To compute <i>neighbors</i> from <i>sf</i>, use:</p> <p>$\text{neighbors} = 1 + \text{floor}(sf * \text{numpts}(\text{srcWaveName}))$.</p> <p>Use either /N or /SMTH, but not both.</p>
/V [=verbose]	<p>Controls how much information to print to the history window. <i>verbose</i> is a binary coded number with each bit controlling one aspect:</p> <p><i>verbose</i>=0: Prints nothing to the history area (default).</p> <p><i>verbose</i>=1: Prints the number of observations, equivalent number of parameters, and residual standard error.</p> <p><i>verbose</i>=2: Prints diagnostic information and error messages.</p> <p>/V alone is the same as /V=3, which prints all information.</p> <p>S_info contains all the informational messages regardless of the value of <i>verbose</i>.</p>
/Z[=z]	<p>Set <i>z</i> to nonzero to prevent an error from stopping execution. Use the V_flag variable to see if the smoothing succeeded.</p>

Basic Algorithm

The basic locally-weighted regression algorithm fits a constant, line, or quadratic to each point of the source data, using data that falls within the given span of neighbors over the factor data. Data outside of the span is ignored (given a weight of zero), and data inside the span is given a weight that depends on the distance of the data from the point being evaluated: data closer to the point being evaluated have higher weights and have a greater affect on the fit.

The basic algorithm uses the “tricube” weighting function to emphasize near values and deemphasize far values. For the one-factor case (simple XY data), the weighting function can be expressed as:

$$w_i = \left(1 - \left| \frac{(x - x_i)}{\max_j (x - x_j)} \right| \right)^3$$

where $\max_j (x - x_j)$ is the maximum Euclidean distance of the *q* factor values within the given span from the factor point (*x*) whose observation (*y*) value is being evaluated.

The weights are applied to the factor values in the span to compute the constant, linear, or quadratic regression at *x*.

When multiple factors are used, the Euclidean distance is computed using one dimension per factor. The default is to normalize each factor's range by the standard deviation of that factor's values before computing the Euclidean distances. When factors are dimensionally equal, use the /NORM=0 option to skip this normalization. (See /NORM, about "dimensionally equal".)

Robust Algorithm

The robust algorithm adds to the basic algorithm a method to identify and remove outliers by rejecting values that exceed a threshold related to the "median absolute deviation" of the basic regression's residuals. The remaining values are used to compute robust "bisquare" weighting values:

$$r_i = \begin{cases} \left(1 - \left| \frac{e_i}{6 \cdot \text{median}(|e_i|)} \right|^2 \right)^2 & \text{for } 0 \leq |e_i| < 6 \cdot \text{median}(|e_i|) \\ 0 & \text{for } (|e_i| \geq 6 \cdot \text{median}(|e_i|)) \end{cases}$$

where e_i is the difference between the observed value and the regression's fitted value, and $\text{median}(|e_i|)$ is evaluated for all the observed values.

These robust weighting values are multiplied with the original weighting values and a new regression (with new residuals) is computed. This process repeats 4 times by default. Use the /PASS flag to specify a different number of repetitions.

Details

Loess sets the variable V_flag to 0 if the smoothing was successful, or to an error code if not. Unlike other operations, the /Z flag allows execution to continue even if input parameters are in error.

Information printed to the history area when /V=3 is always stored in the S_info string, even if /V=0 (the default). S_Info also contains the error message text if V_flag is an error code.

The error messages are described in Cleveland et al. (1992). They are often more dire than they seem.

The error message "Span too small. Fewer data values than degrees of freedom" usually means that the /SMTH or /N values are too small. The error code returned in V_Flag for this case is 1106.

The "Extrapolation not allowed with blending" (V_Flag = 1115) error usually means that the destination factors are trying to compute observations outside of the source factors domain without specifying /E=1. This happens if the /DEST *destWaveName* already exists and has X scaling that extends beyond the X scaling of *srcWaveName*. The solution is either kill the /DEST wave, limit the X scaling to the domain of the source wave, or use /E=1.

Memory Details

Loess requires a lot of memory, especially with the /CONF flag. Even without /CONF, the memory allocations exceed this approximation:

Number of bytes allocated = number of points in *srcWaveName* * 216

With /CONF, Loess can allocate large amounts of memory, approximately $N \times N \times 8$ bytes, where N is the number of points in *srcWaveName*. The 2GB memory limit of 32-bit addressing limits *srcWaveName* to approximately 10,000 points when using /CONF.

More precisely, the memory allocation may be approximated by this function:

```
Function ComputeLoessMemory(srcPoints, numFactorsWaves, doConfidence)
  Variable srcPoints          // number of points in srcWave, aka N
  Variable numFactorsWaves    // 1 or number of factors (independent variables)
  Variable doConfidence       // true if /CONF is specified

  Variable doubles= 9 * srcPoints          // 9 allocated double arrays
  doubles += 5 * numFactorsWaves * srcPoints // 5 more arrays
  doubles += (1+numFactorsWaves) * srcPoints // another array
  doubles += (1+numFactorsWaves) * srcPoints // another array
  doubles += (4+5) * srcPoints             // two more arrays
  if( doConfidence )
    doubles += srcPoints*srcPoints         // one HUGE array
  endif
  Variable bytes= doubles * 8
  return bytes
End

Macro DemoLoessMemory()
  Make/O wSrcPoints={10,100,1000,2000,3000,5000,7500,10000,12500,15000,20000}

log

log (num)

The log function returns the log base 10 of *num*.

It returns -INF if *num* is 0, and returns NaN if *num* is less than 0.

logNormalNoise

logNormalNoise (m, s)

The logNormalNoise function returns a pseudo-random value from the lognormal distribution function whose probability distribution function is

$$f(x, m, s) = \frac{1}{xs\sqrt{2\pi}} \exp\left\{-\frac{1}{2s^2}[\log(x) - m]^2\right\}, \quad x > 0$$

with a mean $\exp\left(m + \frac{1}{2}s^2\right)$ and variance $\exp(2m^2 + s^2)[\exp(s^2) - 1]$.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **SetRandomSeed**.

LowerStr

LowerStr (str)

The LowerStr function returns a string expression identical to *str* except that all upper-case characters are converted to lower-case.

See Also

The **UpperStr** function.

Macro

Macro macroName([parameters]) [:macro type]

The Macro keyword introduces a macro. The macro will appear in the Macros menu unless the procedure file has an explicit Macros menu definition. See Chapter IV-4, **Macros** and **Macro Syntax** on page IV-80 for further information.

MacroList

MacroList(*matchStr*, *separatorStr*, *optionsStr*)

The MacroList function returns a string containing a list of the names of user-defined procedures that start with the Proc, Macro, or Window keywords that also satisfy certain criteria. Note that if the procedures need to be compiled, then MacroList may not list all of the procedures.

Parameters

Only functions having names that match *matchStr* string are listed. See **WaveList** for examples.

The first character of *separatorStr* is appended to each function name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-144 for details on list processing).

optionsStr is used to further qualify the wave. It is a string containing keyword-value pairs separated by commas. Available options are:

KIND: <i>nk</i>	<i>nk</i> =1: List Proc procedures. <i>nk</i> =2: List Macro procedures. <i>nk</i> =4: List Window procedures. <i>nk</i> can be the sum of these values to match multiple procedure kinds. For example, use 3 to list both Proc and Macro procedures.
NPARAMS: <i>np</i>	Restricts the list to functions having exactly <i>np</i> parameters. Omitting this option lists functions having any number of parameters.
SUBTYPE: <i>typeStr</i>	Lists functions that have the type <i>typeStr</i> . That is, you could use ButtonControl as <i>typeStr</i> to list only functions that are action procedures for buttons.
WIN: <i>windowNameStr</i>	Lists functions that are defined in the named procedure window. "Procedure" is the name of the built-in procedure window. Note: Because <i>optionsStr</i> keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN: keyword must be the last one specified.

Examples

To list all Macros with three parameters:

```
Print MacroList("*", ";", "KIND:2,NPARAMS:3")
```

To list all Macro, Proc, and Window procedures in the main procedure window whose names start with b:

```
Print MacroList("b*", ";", "WIN:Procedure")
```

For details on procedure subtypes, see **Procedure Subtypes** on page IV-149, as well as **Button**, **CheckBox**, **SetVariable**, and **PopupMenu**.

magsqr

magsqr(*z*)

The magsqr function returns the sum of the squares of the real and imaginary parts of the complex number *z*, that is, the magnitude squared.

Examples

Assume waveCmplx is complex and waveReal is real.

```
waveReal = sqrt(magsqr(waveCmplx))
```

sets each point of waveReal to the magnitude of the complex points in waveCmplx.

You may get unexpected results if the number of points in waveCmplx differs from the number of points in waveReal because of interpolation. See **Mismatched Waves** on page II-85 for details.

See Also

The **cabs** function.

WaveMetrics provides Igor Technical Note 006, “DSP Support Macros” which uses the magsqr function to compute the magnitude of FFT data, and Power Spectral Density with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the “WaveMetrics Procedures:Analysis:” folder.

Make

Make [*flags*] *waveName* [, *waveName*]...
Make [*flags*] *waveName* [= { *n0*, *n1*, ... }]...
Make [*flags*] *waveName* [= { { *n0*, *n1*, ... }, { *n0*, *n1*, ... }, ... }]...

The Make operation creates the named waves. Use braces to assign data values when creating the wave.

Flags

/B Makes 8-bit signed integer waves or unsigned waves if /U is present.
 /C Makes complex waves.
 /D Makes double precision waves.
 /I Makes 32-bit signed integer waves or unsigned waves if /U is present.
 /N=*n* *n* is the number of points each wave will have. If *n* is an expression, it must be enclosed in parentheses: Make/N=(myVar+1) aNewWave
 /N=(*n1*, *n2*, *n3*, *n4*)
n1, *n2*, *n3*, *n4* specify the number of rows, columns, layers and chunks each wave will have. Trailing zeros can be omitted (e.g., /N=(*n1*, *n2*, 0, 0) can be abbreviated as /N=(*n1*, *n2*)).
 /O Overwrites existing waves in case of a name conflict. After an overwrite, you cannot rely on the contents of the waves and you will need to reinitialize them or to assign appropriate values.
 /R Makes real value waves (default).
 /T Makes text waves.
 /U Makes unsigned Integer waves.
 /W Makes 16-bit signed integer waves or unsigned waves if /U is present.

As a replacement for the above number type flags you can use /Y=*numType* to set the number type as an integer code. See the **WaveType** function for code values. The /Y flag overrides other type flags but you may still need to use the /C or /T flags to define the type of an automatic WAVE reference variable when used in user functions.

Details

Unless overridden by the flags, the created waves have the default length, type, precision, units and scaling. The factory defaults are:

Property	Default
Number of points	128
Precision	Single precision floating point
Type	Real
dimensions	1
x, y, z, and t scaling	offset=0, delta=1 (“point scaling”)
x, y, z, and t units	" " (blank)
Data Full Scale	0, 0
Data units	" " (blank)

Note: The *preferred* precision set by the Miscellaneous Settings dialog only presets the Make Waves dialog checkbox and determines the precision of imported waves. It does not affect the Make operation.

See Also

The **SetScale**, **Duplicate**, and **Redimension** operations.

MakeIndex

MakeIndex [/A/C/R] *sortKeyWaves*, *indexWaveName*

The MakeIndex operation sets the data values of *indexWaveName* such that they give the ordering of *sortKeyWaves*.

For simple sorting problems, MakeIndex is not needed. Just use the **Sort** operation.

Parameters

sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

indexWaveName must specify a numeric wave.

All waves must be of the same length and must not be complex.

Flags

- /A Alphanumeric. When *sortKeyWaves* includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”. Use /A to sort the number portion numerically, so that “wave9” is sorted before “wave10”.
- /C Case-sensitive. When *sortKeyWaves* includes text waves, the ordering is case-insensitive unless you use the /C flag which makes it case-sensitive.
- /R Reverse the index so that ordering is from largest to smallest.

Details

MakeIndex is used in preparation for a subsequent **IndexSort** operation. If /R is used the ordering is from largest to smallest. Otherwise it is from smallest to largest.

See Also

MakeIndex and IndexSort Operations on page III-135.

MarcumQ

MarcumQ(*m*, *a*, *b*)

The MarcumQ function returns the generalized Q-function defined by the integral

$$Q_m(a,b) = \int_b^{\infty} u \left(\frac{u}{a}\right)^{m-1} \exp\left(-\frac{(a^2 + u^2)}{2}\right) I_{m-1}(au) du$$

where I_k is the modified Bessel function of the first kind and order k .

Depending on the input arguments, the MarcumQ function may be computationally intensive but you can abort the calculation at any time.

References

Cantrell, P.E., and A.K. Ojha, Comparison of Generalized Q-Function Algorithms, *IEEE Transactions on Information Theory*, IT-33, 591-596, 1987.

MarkPerfTestTime

MarkPerfTestTime *idval*

Use the MarkPerfTestTime operation for performance testing of user-defined functions in conjunction with SetIgorOption DebugTimer. When used between SetIgorOption DebugTimer, Start and SetIgorOption DebugTimer, Stop, MarkPerfTestTime stores the ID value and the time of the call in a buffer. When SetIgorOption DebugTimer, Stop is called the contents of the buffer are dumped to a pair of waves: W_DebugTimerIDs will contain the ID values and W_DebugTimerVals will contain the corresponding times of the calls relative to the very first call. The timings use the same high precision mechanism as the startMSTimer and stopMSTimer calls.

By default, SetIgorOption DebugTimer, Start allocates a buffer for up to 10000 entries. You can allocate a different sized buffer using SetIgorOption DebugTimer, Start=bufsize.

See Also

SetIgorOption, **startMSTimer**, and **stopMSTimer**.

Additional documentation can be found in an example experiment, *PerformanceTesting.pxp*, and a WaveMetrics procedure file, *PerformanceTestReport.ipf*.

MatrixConvolve

MatrixConvolve [/R=*roiWave*] *coefMatrix*, *dataMatrix*

The MatrixConvolve operation convolves a small coefficient matrix *coefMatrix* into the destination *dataMatrix*.

Flags

/R=*roiWave* Modifies only data contained inside the region of interest. The ROI wave should be 8-bit unsigned with the same dimensions as *dataMatrix*. The interior of the ROI is defined by zeros and the exterior is any nonzero value.

Details

On input *coefMatrix* contains an $N \times M$ matrix of coefficients where N and M should be odd. Generally N and M will be equal. If N and M are greater than 13, it is more efficient to perform the using the Fourier transform (see **FFT**).

The convolution is performed in place on the data matrix and is acausal, i.e., the output data is not shifted. Edges are handled by replication of edge data.

When *dataMatrix* is an integer type, the results are clipped to limits of the given number type. For example, unsigned byte is clipped to 0 to 255.

MatrixConvolve works also when both *coefMatrix* and *dataMatrix* are 3D waves. In this case the convolution result is placed in the wave *M_Convolution* in the current data folder, and the optional /R=*roiWave* is required to be an unsigned byte wave that has the same dimensions as *dataMatrix*.

See Also

MatrixFilter and **ImageFilter** for filter convolutions.

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

The **Loess** operation.

MatrixCorr

MatrixCorr [/COV] [/DEGC] *waveA* [, *waveB*]

The MatrixCorr operation computes the correlation or covariance or degree of correlation matrix for the input 1D wave(s).

If we denote elements of *waveA* by $\{x_i\}$ and elements of *waveB* by $\{y_i\}$ then the correlation matrix for these waves is the vector product of the form:

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{bmatrix} \begin{bmatrix} y_1 & y_2 & y_3 & \dots & y_n \end{bmatrix}^* = \begin{bmatrix} x_1 y_1^* & x_1 y_2^* & x_1 y_3^* & \dots & x_1 y_n^* \\ x_2 y_1^* & x_2 y_2^* & x_2 y_3^* & \dots & x_2 y_n^* \\ x_3 y_1^* & x_3 y_2^* & x_3 y_3^* & \dots & x_3 y_n^* \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ x_n y_1^* & x_n y_2^* & x_n y_3^* & \dots & x_n y_n^* \end{bmatrix}$$

where * denotes complex conjugation. If you use the optional *waveB* then the matrix is the cross correlation matrix. *waveB* must have the same length of *waveA* but it does not have to be the same number type.

Flags

The flags are mutually exclusive; only one matrix can be generated at a time.

/COV Calculates the covariance matrix.

The covariance matrix for the same input is formed in a similar way after subtracting from each vector its mean value and then dividing the resulting matrix elements by $(n-1)$ where n is the number of elements of *waveA*.

Results are stored in the *M_Corr* or *M_Covar* waves in the current data folder.

/DEGC Calculates the complex degree of correlation. The degree of correlation is defined by:

$$\text{degC} = \frac{M_Covar}{\sqrt{\text{Var}(waveA) \cdot \text{Var}(waveB)}}$$

here *M_Covar* is the covariance matrix and *Var(wave)* is the variance of the wave.

The complex degree of correlation should satisfy: $0 \leq |\text{degC}| \leq 1$.

Examples

The covariance matrix calculation is equivalent to:

```
Variable N=1/(DimSize(waveA,0)-1)
Variable ma=mean(waveA,-inf,inf)
Variable mb=mean(waveB,-inf,inf)
waveA-=ma
waveB-=mb
MatrixTranspose/H waveB
MatrixMultiply waveA,waveB
M_product*=N
```

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

References

Hayes, M.H., *Statistical Digital Signal Processing And Modeling*, 85 pp., John Wiley, 1996.

MatrixDet

matrixDet(dataMatrix)

The *matrixDet* function returns the determinant of *dataMatrix*. The matrix wave must be a real, square matrix or else the returned value will be NaN.

Details

The function calculates the determinant using LU decomposition. If, following the decomposition, any one of the diagonal elements is either identically zero or equal to 10^{-100} , the return value of the function will be zero.

See Also

The **MatrixOP** operation for more efficient matrix operations.

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixDot

MatrixDot(waveA, waveB)

The *MatrixDot* function calculates the inner (scalar) product for two 1D waves. A 1D wave **A** represents a vector in the sense:

$$\mathbf{A} = \sum (\alpha_i \hat{e}_i), \quad \hat{e}_i \text{ is a unit vector.}$$

Given two such waves **A** and **B**, the inner product is defined as

$$ip = \sum \alpha_i \beta_i.$$

When both *waveA* and *waveB* are complex and the result is assigned to a complex-valued number *MatrixDot* returns:

$$ipc = \sum \alpha_i^* \beta_i.$$

If the result is assigned to a real number, *MatrixDot* returns:

$$ip = \left| \sum \alpha_i^* \beta_i \right|.$$

If either *waveA* or *waveB* is complex and the result is assigned to a real-valued number, *MatrixDot* returns:

$$ip = |\sum \alpha_i \beta_i|.$$

When the result is assigned to a complex-valued number MatrixDot returns:

$$ipc = \sum \alpha_i \beta_i.$$

See Also

The **MatrixOP** operation for more efficient matrix operations.

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixEigenV

MatrixEigenV [*flags*] *matrixWave*

The MatrixEigenV operation computes the eigen values and eigen vectors of a square matrix using LAPACK routines. There are two mutually exclusive branches for the operation. The first is designed for a general square matrix and uses the appropriate routines depending on the data type of *matrixWave*. The second branch is designed for symmetric matrices. The first group, Flags for General Matrices, applies to general matrices only. The second group, Flags for Symmetric Matrices, applies to symmetric matrices only while the /Z flag applies to both. Both branches support single and double precision in real or complex waves.

Flags for General Matrices

/B= <i>balance</i>	Determines how the input matrix should be scaled and or permuted to improve the conditioning of the eigen values. <i>balance</i> =0 (default), 1, 2, or 3, corresponding respectively to N, P, S, or B in the LAPACK routines. Applicable only with the /X flag. 0: Do not scale or permute. 1: Permute. 2: Do diagonal scaling. 3: Scale and permute.
/L	Calculates for left eigen vectors.
/O	Overwrites <i>matrixWave</i> , requiring less memory.
/R	Calculates for right eigen vectors.
/S= <i>sense</i>	Determines which reciprocal condition numbers are calculated. <i>sense</i> =0 (default), 1, 2, or 3, corresponding respectively to N, E, V, or B in the LAPACK routines. Applicable only with the /X flag. 0: None. 1: Eigen values only. 2: Right eigen vectors. 3: Eigen values and right eigen vectors.
/X	Uses LAPACK expert routines, which require additional parameters (see /B and /S flags). The operation creates additional waves. The W_MatrixOpInfo wave contains in element 0 the ILO, in element 1 the IHI, and in element 2 the ABNRM from the LAPACK routines. The wave W_MatrixRCONDE contains the reciprocal condition numbers for the eigen values, and the wave W_MatrixRCONDV contains the reciprocal condition number for the eigen vectors.

LAPACK Flags

N	Do not diagonally scale or permute.
P	Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale.
S	Diagonally scale the <i>matrixWave</i> , i.e., replace <i>matrixWave</i> by $D * matrixWave * D^{**(-1)}$, where D is the diagonal matrix calculated to make the rows and columns of <i>matrixWave</i> more equal in the norm. Do not permute.
B	Both diagonally scale and permute <i>matrixWave</i> .

Flags for Symmetric Matrices

- /SYM Computes the eigen values of an NxN symmetric matrix and stores them in the wave W_eigenValues. You must specify this flag if you want to use the special routines for symmetric matrices. The number of eigen values is stored in the variable V_npnts. Because W_eigenValues has N points, only the first V_npnts will contain relevant eigen values.
- /EVEC Computes eigen vectors in addition to eigen values. Eigen values will be stored in the wave M_eigenVectors, which is of dimension NxN. The first V_npnts columns of the wave will contain the V_npnts eigen vectors corresponding to the eigen values in W_eigenValues.
- /RNG={method,low,high}
- method=0: Computes all the eigen values or eigen vectors (default).
 - method=1: Computes eigen values for *low* and *high* double precision range.
 - method=2: Computes eigen values for *low* and *high* integer indices (1 based). For example, to compute the first 3 eigen values use: /RNG={2,1,3}.

General Flags

- /Z No error reporting (except for setting V_flag).

Details for General Matrices

The eigen values are stored in the 1D complex wave W_eigenValues. The eigen vectors are stored in the 2D wave M_R_eigenVectors or M_L_eigenVectors.

The calculated eigen vectors are normalized to unit length.

Complex conjugate pairs of eigen values appear consecutively with the eigen value having the positive imaginary part first.

If the *j*th eigen value is real, then the corresponding eigen vector $u(j)=M[][j]$ is the *j*th column of M_L_eigenVectors or M_R_eigenVectors. If the *j*th and (*j*+1)th eigen values form a complex conjugate pair, then $u(j) = M[][j] + i*M[][j+1]$ and $u(j+1) = M[][j] - i*M[][j+1]$.

The variable V_flag is set to 0 when there is no error.

Details for Symmetric Matrices

The LAPACK routines that compute the eigen values and eigen vectors of symmetric matrices claim to use the Relatively Robust Representation whenever possible.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

Symmetric matrices can also be decomposed using the **MatrixSchur** operation.

MatrixFilter

MatrixFilter [flags] Method dataMatrix

The MatrixFilter operation performs one of several standard image filter type operations on the destination dataMatrix.

Note: The parameters below are also available in ImageFilter. See **ImageFilter** for additional parameters.

Parameters

Method selects the filter type. Method is one of the following names:

- avg *nxn* average filter.
- FindEdges 3x3 edge finding filter.
- gauss *nxn* gaussian filter.
- gradN, gradNW, gradW, gradSW, gradS, gradSE, gradE, gradNE 3x3 North, NorthWest, West, ... pointing gradient filter.
- median *nxn* median filter. You can assign values other than the median by specifying the desired rank using the /M flag.
- min *nxn* minimum rank filter.
- max *nxn* maximum rank filter.

NanZapMedian	$n \times n$ filter that only affects data points that are NaN. Replaces them with the median of the $n \times n$ surrounding points. Unless /P is used, automatically cycles through matrix until all NaNs are gone or until $cols \times rows$ iterations.
point	3x3 point finding filter $8 * center - outer$.
sharpen	3x3 sharpening $filter = (12 * center - outer) / 4$.
sharpenmore	3x3 sharpening $filter = (9 * center - outer)$.
thin	Calculates binary image thinning using neighborhood maps based on the algorithm in <i>Graphics Gems IV</i> , p. 465. Note: The thin keyword to MatrixFilter will be removed someday. The functionality will be available — just not as a part of MatrixFilter. The /R flag does not apply to the lame duck thin keyword.
Flags	
/B=b	Specifies value that is considered background. Used with thin. If object is black on white background, use 255. If object is white on a black background, use 0.
/M=rank	Assigns a pixel value other than the median when used with the median filter. Valid rank values are between 0 and $n^2 - 1$ (for the default median $rank = n^2 / 2$).
/N=n	For any method described above as “ $n \times n$ ”, you can specify that the filtering kernel will be a square matrix of size n . In the absence of the /N flag, the default size is 3.
/P=p	Filter passes over the data p times. The default is one pass.
/R=roiWave	Only the data outside the region of interest will be modified. roiWave should be an 8-bit unsigned wave with the same dimensions as the data matrix. The exterior of the ROI is defined by zeros and the interior is any nonzero value.
/T	Applies the thinning algorithm of Zhang and Suen with the thin parameter. The wave M_MatrixFilter contains the results; the input wave is not overwritten.

MatrixGaussJ

MatrixGaussJ matrixA, vectorsB

The MatrixGaussJ operation solves matrix expression $A * x = b$ for column vector x given matrix A and column vector b . The operation can also be used to calculate the inverse of a matrix.

Parameters

matrixA is a $N \times N$ matrix of coefficients and *vectorsB* is a $N \times M$ set of right-hand side vectors.

Details

On output, the array of solution vectors x is placed in M_x and the inverse of A is placed in $M_Inverse$.

If the result is a singular matrix, V_flag is set to 1 to indicate the error. All other errors result in an alert, and abort any calling procedure.

All output objects are created in the current data folder.

An error is generated if the dimensioning of the input arrays is invalid.

This routine is provided for completeness only and is not recommended for general work (use LU decomposition — see **MatrixLUD**). MatrixGaussJ does calculate the inverse matrix but that is not generally needed either.

See Also

Matrix Math Operations on page III-139 for more about Igor’s matrix routines. The **MatrixLUD** operation.

MatrixInverse

MatrixInverse [*flags*] *srcWave*

The MatrixInverse operation calculates the inverse or the pseudo-inverse of a square matrix. *srcWave* may be real or complex.

MatrixInverse saves the result in the wave M_Inverse in the current data folder.

Flags

- /D Creates the wave W_W that contains eigen values of the singular value decomposition (SVD) for the pseudo-inverse calculation. If one or more of the eigen values are small, the matrix may be close to singular.
- /G Calculates only the direct inverse; does not affect calculation of pseudo-inverse. By default, it calculates the inverse of the matrix using LU decomposition. The inverse is calculated using Gauss-Jordan method. The only advantage in using Gauss-Jordan is that it is more likely to flag singular matrices than the LU method.
- /O Overwrites the source with the result.
- /P Calculates the pseudo-inverse of a square matrix using the SVD algorithm. The calculated pseudo-inverse is a unique minimal solution to the problem: $\min \|AX - Im\|$.
 X belongs to $R^{m \times n}$.

MatrixLinearSolve

MatrixLinearSolve [*flags*] *matrixA matrixB*

The MatrixLinearSolve operation solves the linear system $matrixA * X = matrixB$ where *matrixA* is an N-by-N matrix and *matrixB* is an N-by-NRHS matrix of the same data type.

Flags

- /M=*method* Determines the solution method which best suites input *matrixA*.
 - method*=1: Uses simple LU decomposition (default). See also LAPACK documentation for SGESV, CGESV, DGESV, and ZGESV.
Creates the wave W_IPIV that contains the pivot indices that define the permutation matrix P. Row (i) if the matrix was interchanged with row ipiv(i).
 - method*=2: If *matrixA* is band diagonal, you also have to specify /D. See also LAPACK documentation for SGBSV, CGBSV, DGBSV, and ZGBSV.
Creates the wave W_IPIV, which contains the pivot indices that define the permutation matrix P. Row (i) if the matrix was interchanged with row ipiv(i). Also note that if you are using the /O flag, the overwritten waves may have a different dimensions.
 - method*=4: For tridiagonal matrix; still expecting full matrix in *matrixA*, but it will ignore the data in the elements outside the 3 diagonals. See also LAPACK documentation for SGTSV, CGTSV, DGTSV, and ZGTSV.
 - method*=8: Symmetric/hermitian. See also LAPACK documentation for SPOSV, CPOSV, DPOSV, and ZPOSV.
 - method*=16: Complex symmetric (complex only). See also LAPACK documentation for CSYSV and ZSYSV.
- /D={*sub,super*} Specifies a band diagonal matrix. The subdiagonal (*sub*) and superdiagonal (*super*) size must be positive integers.
- /L Uses the lower triangle of *matrixA*. /L and /U are mutually exclusive flags.
- /U Uses the upper triangle of *matrixA*. /U is the default.

- /O Overwrites *matrixA* and *matrixB* with the results of the operation. This will save on the amount of memory needed.
- /Z No error reporting.

Details

If /O is not specified, the operation also creates the n-by-n wave M_A and the n-by-nrhs solution wave M_B.

The variable V_flag is created by the operation. If the operation completes successfully, V_flag is set to zero, otherwise it is set to the LAPACK error code.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixLinearSolveTD

MatrixLinearSolveTD [/Z] *upperW, mainW, lowerW, matrixB*

The MatrixLinearSolveTD operation solves the linear system $TDMatrix \cdot X = matrixB$. In the matrix product on the left hand side, *TDMatrix* is a tridiagonal matrix with upper diagonal *upperW*, main diagonal *mainW*, and lower diagonal *lowerW*. It solves for vector(s) X depending on the number of columns (NRHS) in *matrixB*.

Flags

- /Z No error reporting.

Details

The input waves can be single or double precision (real or complex). Results are returned in the wave M_TDLinearSolution in the current data folder. The wave *mainW* determines the size of the main diagonal (N). All other waves must match it in size with *upperW* and *mainW* containing one less point and *matrixB* consisting of N-by-NRHS elements of the same data type.

MatrixLinearSolveTD should be more efficient than MatrixLinearSolve with respect to storage requirements.

MatrixLinearSolveTD creates the variable V_flag, which is zero when it finishes successfully.

See Also

Matrix Math Operations on page III-139; the **MatrixLinearSolve** and **MatrixOP** operations.

MatrixLLS

MatrixLLS [/O/Z/M=method] *matrixA matrixB*

The MatrixLLS operation solves overdetermined or underdetermined linear systems involving MxN *matrixA*, using either QR/LQ or SV decompositions. Both *matrixA* and *matrixB* must have the same number type. Supported types are real or complex single precision and double precision numbers.

Flags

- /M=method Specifies the decomposition method.
- method*=0: Decomposition is to QR or LQ (default). Creates the 2D wave M_A, which contains details of the QR/LQ factorization.
- method*=1: Singular value decomposition. Creates the 2D wave MA, which contains the right singular vectors stored row-wise in the first $\min(m, n)$ rows. Creates the 1D wave M_SV, which contains the singular values of *matrixA* arranged in decreasing order.
- /O Overwrites *matrixA* with its decomposition and *matrixB* with the solution vectors. This requires less memory.
- /Z No error reporting.

Details

When the /O flag is not specified, the solution vectors are stored in the wave M_B, otherwise the solution vectors are stored in *matrixB*. Let *matrixA* be *m* rows by *n* columns and *matrixB* be an *m* by NRHS (if NRHS=1 it can be omitted). If $m \geq n$, MatrixLLS solves the least squares solution to an overdetermined system: Minimize $\| matrixB - matrixA \cdot X \|$.

MatrixLUBkSub

Here the first n rows of M_B contain the least squares solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares. If you are not interested in the residual you can resize the wave using, for example:

Redimension/N=(n,NRHS) M_B

If $m < n$, MatrixLLS finds the minimum norm solution of the underdetermined system:

$$\text{matrix}A \cdot X = \text{matrix}B.$$

In this case, the first m rows of M_B contain the minimum norm solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares for the solution. If you are not interested in the residual you can resize the wave using, for example:

Redimension/N=(m,NRHS) M_B

Note: Here $\text{matrix}B$ consists of one or more column vectors B corresponding to one or more solution vectors X that are computed simultaneously. If $\text{matrix}B$ consists of a single column, M_B is a 2D matrix wave that contains a single solution column.

The variable V_flag is set to 0 when there is no error; otherwise it contains the LAPACK error code.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixLUBkSub

MatrixLUBkSub *matrtixL, matrixU, index, vectorB*

The MatrixLUBkSub operation provides back substitution for LU decomposition.

Details

This operation is used to solve the matrix equation $Ax=b$ after you have performed LU decomposition (see **MatrixLUD**). Feed this routine M_Lower , M_Upper and $W_LUPermutation$ from MatrixLUD along with your right-hand-side vector b . The solution vector x is returned as M_x . The array b can be a matrix containing a number of b vectors and the M_x will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixLUD

MatrixLUD *matrixA*

The MatrixLUD operation decomposes $N \times N$ wave, $\text{matrix}A$, into a pair of upper and lower triangular matrices.

Details

The output matrices are placed into waves named M_Upper and M_Lower . A permutation wave is returned in $W_LUPermutation$. This is needed for the back substitution routine, **MatrixLUBkSub**.

The variable V_flag is set to zero if the operation succeeds and to 1 if singular. The polarity of the matrix is returned in the variable $V_LUPolarity$.

All output objects are created in the current data folder.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixMultiply

MatrixMultiply *matrixA* [/T], *matrixB* [/T] [, *additional matrices*]

The MatrixMultiply operation calculates matrix expression $\text{matrix}A * \text{matrix}B$ and puts the result in a matrix wave named $M_product$ generated in the current data folder. The /T flag can be included to indicate that the transpose of the specified matrix should be used.

If any of the source matrices are complex, then the result is complex.

Parameters

If *matrixA* is an NxP matrix then *matrixB* must be a PxM matrix and the product is an NxM matrix. Up to 10 matrices can be specified although it is unlikely you will need more than three. The inner dimensions must be the same. Multiplication is performed from right to left.

It is legal for *M_product* to be one of the input matrices. Thus `MatrixMultiply A,B,C` could also be done as:

```
MatrixMultiply B,C
MatrixMultiply A,M_product
```

Details

Supports multiplication of complex matrices.

An error is generated if the dimensioning of the input arrays is invalid.

See Also

The **MatrixOP** operation for more efficient matrix operations.

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixOP

MatrixOp [/C/O/S] *destwave* = *matrixExpression*

The MatrixOP operation improves the execution efficiency and readability of matrix expressions over standard Igor syntax.

For example, the expression

```
MatrixOP matA = Inv((Identity(vecSize) - matB x matC) x matD)
```

is equivalent to:

```
Make/O/N=(vecSize,vecSize) identityMatrix = p==q ? 1 : 0
MatrixMultiply matB,matC
identityMatrix--M Product
MatrixMultiply identityMatrix,matD
MatrixInverse M_Product
ReName M_Inverse, matA
```

Parameters

destWave

Specifies a destination wave for the assignment expression. *destWave* will be created at runtime. If it already exists, you must use the /O flag to overwrite it or the operation will generate an error. When the operation finishes, *destWave* has the dimensions and data type implied by the operation. In particular, it may be complex if the matrix expression evaluates to a complex quantity. If the matrix expression evaluates to a scalar, *destWave* is a 1x1 wave.

The data type of *destWave* depends on the data types of the operands and the nature of the operations on the right-hand side of the equation. If you are only working with integer waves, *destWave* is an integer but all operation with a scalars convert *destWave* into a double precision wave. **Note:** even if *destWave* exists before the operation, you do not need to modify it's data type or dimensionality. MatrixOP will do it for you.

matrixExpression

Represents an algebraic expression containing waves, local variables, global variables, and numerical constants together with the following operators:

MatrixOP Operator	Precedence
^h ^t	Highest
x	
* /	
+ -	
&&	Lowest

Operators

The following operators work as described only with MatrixOP.

+	Addition between scalars, matrix addition or addition of a scalar (real or complex) to each element of a matrix.
-	Subtraction of one scalar from another, matrix subtraction, or subtracting a scalar from each element of a matrix. Subtraction of a matrix from a scalar is not defined.
*	Multiplication between two scalars, multiplication of a matrix by a scalar, or element-by-element multiplication of two waves of the same dimensions.
/	Division of two scalars, division of a matrix by a scalar, or element-by-element division between two waves of the same dimensions.
x	Matrix multiplication (lower case symbol only). Operator <i>must</i> be preceded and followed by a space. Matrix multiplication requires that the number of columns in the matrix on the left side be equal to the number of rows in the matrix on the right.
.	Generalized form of a dot product. In an expression $a.b$ it is expected that a and b have the same number of points although they may be of arbitrary numeric type. The operator returns the sum of the products of the sequential elements as if both a and b were 1D arrays.
^t	Matrix transpose.
^h	Hermitian transpose.
&&	Logical AND operator supports all real data types and results in signed byte numerical type with values of either 0 or 1. The operation acts on an element by element basis and it therefore does not stop evaluation if the left hand operand of a logical AND is zero.
	Logical OR operator supports all real data types and results in signed byte numerical type with values of either 0 or 1.

Functions

These functions are only available for use with MatrixOP.

Abs ()	Absolute value of a real number or the magnitude of a complex number.
acos (z)	Arc cosine of the generic argument z .
asin (z)	Arc sine of the generic argument z .
asyncCorrelation (w)	Asynchronous spectrum correlation matrix for a real valued input matrix wave w . See also <code>syncCorrelation</code> .
atan (z)	Arc tangent of the generic argument z .
atan2 (y , x)	Arc arc tangent of real y/x .
beam (w3D , row , col)	Returns a 1D array corresponding to the data in the beam defined by $w3D$ [row][col][] (see also ImageTransform <code>getBeam</code>). The beam function belongs to a special class in that it does not operate layer by layer. It therefore does not permit compound expressions in place of any of its parameters. The beam function has the highest precedence.
ceil (z)	Smallest integer larger than z .
ChirpZ (data , A , W , M)	Chirp Z Transform of the 1D wave data calculated for the contour defined by $z_k = AW^{-k} \quad k = 0, 1, \dots, M-1$ where both A and W are complex and the standard z transform for a sequence $\{x(n)\}$ is defined by $X(z) = \sum_{n=0}^{n-1} x(n)z^{-n}$ The phase of the output is inverted to match the result of the ChirpZ transform on the unit circle with that of the FFT.
ChirpZf (data , f1 , f2 , df)	Chirp Z Transform except that the transform parameters are specified by real-valued starting frequency $f1$, end frequency $f2$ and frequency resolution df . The transform is confined to the unit circle because both A and W have unit magnitude.

<code>col(w, c)</code>	Returns column <i>c</i> from matrix wave <i>w</i> .
<code>Conj(matrixWave)</code>	Ccomplex conjugate of the input expression.
<code>convolve(w1, w2, opt)</code>	Convolution of <i>w1</i> with <i>w2</i> subject to options <i>opt</i> . The dimensions of the result are determined by the largest dimensions of <i>w1</i> and <i>w2</i> with the number of rows padded (if necessary) so that they are even. Supported options include <i>opt</i> =0 for circular convolution and <i>opt</i> =4 for acausal convolution.
<code>correlate(w1, w2, opt)</code>	Correlation of <i>w1</i> with <i>w2</i> subject to options <i>opt</i> . The dimensions of the result are determined by the largest dimensions of <i>w1</i> and <i>w2</i> with the number of rows padded (if necessary) so that they are even. Supported options include <i>opt</i> =0 for circular correlation and <i>opt</i> =4 for acausal correlation.
<code>cos(z)</code>	Cosine of the generic argument <i>z</i> .
<code>Det(matrixWave)</code>	Scalar corresponding to the determinant of <i>matrixWave</i> , which must be real.
<code>Diagonal(wave1D)</code>	Creates a square matrix that has the same number of rows as <i>wave1D</i> . All entries are zero except for the diagonal elements for which the entries are taken from the first column in <i>wave1D</i> . Use <code>DiagRC</code> if the input is not an existing wave (such as a result from another function).
<code>DiagRC(waveA, rows, cols)</code>	2D matrix of dimensions <i>rows</i> by <i>cols</i> . All matrix elements are set to zero except those of the diagonal which are filled sequentially from elements of <i>waveA</i> . The dimensionality of <i>waveA</i> is unimportant. If the total number of elements in <i>waveA</i> is less than the number of elements on the diagonal then all elements will be used and the remaining diagonal elements will be set to zero.
<code>e</code>	Returns the base of the natural logarithm.
<code>equal(a, b)</code>	Returns unsigned byte result with 1 for equality and zero otherwise. The dimensionality of the result matches the dimensionality of the largest parameter. Either or both <i>a</i> or <i>b</i> can be constants (i.e., one row by one column). If <i>a</i> and <i>b</i> are not constants, they must have the same dimensions. Both parameters can be either real or complex. A comparison of a real with a complex parameter returns zero.
<code>exp(z)</code>	Exponential function for a generic argument <i>z</i> , which can be real or complex, scalar or a matrix.
<code>FFT(inWave, options)</code>	FFT of <i>inWave</i> subject to the <i>options</i> field. <i>inWave</i> must have an even number of rows. The options field contains a binary field flag. Set the second bit to 1 if you want to disable the zero centering (see /Z flag in the FFT operation). Other bits are reserved. MatrixOP does not support wave scaling and therefore it does not produce the same wave scaling changes as the FFT operation.
<code>floor(z)</code>	Largest integer smaller than <i>z</i> .
<code>Frobenius(matWave)</code>	Returns the Frobenius norm of a matrix defined as the square root of the sum of the squared absolute values of all elements.
<code>greater(a, b)</code>	Returns an unsigned byte for the truth of <i>a</i> > <i>b</i> . Both <i>a</i> and <i>b</i> must be real but one or both can be constants (see <code>equal()</code> above). The dimensionality of the result matches the dimensionality of the largest parameter.
<code>IFFT(inWave, options)</code>	IFFT of <i>inWave</i> subject to the <i>options</i> field. The <i>options</i> field corresponds to the /C and /Z flags of the IFFT operation. Set the first bit to 1 if you want to allow real-valued output (in the case of a complex input of 2n+1 rows. Set the second bit to 1 if you want to disable the zero centering. Other bits are reserved. Note that MatrixOP does not support wave scaling and therefore it does not produce the same wave scaling changes as the IFFT operation.
<code>Identity(n, m)</code> <code>Identity(n)</code>	Creates a computational object that is an identity matrix. If you use a single argument <i>n</i> , the identity created is an <i>n</i> × <i>n</i> square matrix with 1's for diagonal elements (the remaining elements are set to zero). If you use both arguments, the function creates an <i>n</i> × <i>m</i> zero matrix and fills its diagonal elements with 1's. Note that the identity is created at runtime and persists only for the purpose of the specific operation.

<code>imag(inWave)</code>	Imaginary part of <i>inWave</i> .
<code>Inv(matrixWave)</code>	Inverse of a square <i>matrixWave</i> .
<code>log(z)</code>	Log (i.e., log base 10) of a generic argument <i>z</i> which can be real or complex, scalar or a matrix.
<code>ln(z)</code>	Natural logarithm of a generic argument <i>z</i> which can be real or complex, scalar or a matrix.
<code>mag(inWave)</code>	Returns a real valued wave containing the magnitude of each element of <i>inWave</i> . This is equivalent to the <code>Abs()</code> function.
<code>magSqr(inWave)</code>	Returns a real value wave containing the square of a real <i>inWave</i> or the squared magnitude of complex <i>inWave</i> .
<code>Normalize(inWave)</code>	Normalized version of a vector or a matrix. Normalization is such that the returned wave should have a unity magnitude except if all entries are zero, in which case output is unchanged.
<code>NormalizeCols(w)</code>	Divides each column of the real wave <i>w</i> with the square root of the sum of the squares of all elements of the column.
<code>NormalizeRows(w)</code>	Divides each row of the real wave <i>w</i> with the square root of the sum of the squares of all the elements in that row.
<code>numType(z)</code>	Number type for the element passed to this function.
<code>p2Rect(inWave)</code>	Performs the equivalent of the <code>p2rect</code> function on each element of <i>inWave</i> , i.e., each complex number of <i>inWave</i> is converted from polar to rectangular representation.
<code>phase(inWave)</code>	Returns a real valued wave containing the phase of each element of <i>inWave</i> calculated using <code>phase=atan2(y,x)</code> .
<code>Pi</code>	Returns π .
<code>powC(z1,z2)</code>	Complex valued $z1^{z2}$ where <i>z1</i> and <i>z2</i> can be real or complex.
<code>powR(x,y)</code>	Returns x^y for real <i>x</i> and <i>y</i> .
<code>r2Polar(inWave)</code>	Performs the equivalent of the <code>r2polar</code> function on each element of <i>inWave</i> , i.e., each complex number (<i>x</i> + <i>iy</i>) is converted into the polar representation <i>r</i> , <i>theta</i> with $x+iy=r*\exp(i*theta)$
<code>real(inWave)</code>	Real part of <i>inWave</i> .
<code>rec(inWave)</code>	Reciprocal of each element in <i>inWave</i> .
<code>round(z)</code>	Rounds <i>z</i> to the nearest integer. The rounding method is away from zero.
<code>row(w,r)</code>	Returns row <i>r</i> from matrix wave <i>w</i> . The returned row is a (1xC) wave where C is the number of columns in <i>w</i> . To convert it to a 1D wave use <code>Redimension/N=(C)</code> . See also <code>ImageTransform.getRow</code> .
<code>sgn(w)</code>	Returns the sign of each element in <i>w</i> . It returns -1 for negative numbers and 1 otherwise. It does not accept complex numbers.
<code>shiftVector(w, n, val)</code>	Shifts the element of a 1D row-vector <i>w</i> by <i>n</i> elements and fills the displaced elements with <i>val</i> , which must match the data type of <i>w</i> and should be expressed as <code>cmplx(a,b)</code> for complex <i>w</i> .
<code>sin(z)</code>	Sine of the generic argument <i>z</i> .
<code>sqrt(z)</code>	Square root of the generic argument <i>z</i> .
<code>SubtractMean(w, opt)</code>	Computes the mean of the real wave <i>w</i> and returns the values of the wave minus the mean value (<i>opt</i> =0). Computes the mean of each column and subtracts it from that column (<i>opt</i> =1). Subtracts the mean of each row from row values (<i>opt</i> =2).
<code>sum(z)</code>	Returns the sum of all the elements in expression <i>z</i> .
<code>sumCols(w)</code>	Returns a 1xcols wave where each element contains the sum of all elements in the corresponding column of <i>w</i> .
<code>sumSqr(inWave)</code>	Sum of the squares of all elements in <i>inWave</i> .
<code>syncCorrelation(w)</code>	Synchronous spectrum correlation matrix for a real valued input matrix wave <i>w</i> . See also <code>asyncCorrelation</code> .

	The correlation matrix is computed by subtracting from each column of w its mean value, multiplying the resulting matrix by its transpose, and finally dividing all entries by $(nrows-1)$ where $nrows$ is the number of rows in w .
<code>tan(z)</code>	Tangent of the generic argument z .
<code>Trace(matrixWave)</code>	Returns a real or complex scalar which is the sum of the diagonal elements of <i>matrixWave</i> . If <i>matrixWave</i> is not a square matrix, the sum is over the elements for which the row and column indices are the same.
<code>TriDiag(w1,w2,w3)</code>	Returns a tri-diagonal matrix where $w1$ is the upper diagonal, $w2$ the main diagonal and $w3$ the lower diagonal. If $w2$ has n points than $w1$ and $w3$ are expected to have $n-1$ points. The waves can be of any numeric type and the returned wave has a numeric type that accommodates the input.
<code>varCols(w)</code>	Returns a 1xcols wave where each element contains the variance of the corresponding column in w .
<code>waveMap(w1,w2)</code>	Returns an array of the same dimensions as $w2$ containing the values $w1[w2[i][j]]$. The data type of the output is the same as that of $w1$. Values of $w2$ are taken as 1D integer indices into the $w1$ array. See also IndexSort .

Wave Arguments

MatrixOP was designed to work with 2D matrices but it also works with a variety of other formats such as the following “nonmatrix” formats:

<code>wave1d[a]</code>	Where a is a constant index or a local variable. This will be converted into a constant equal to the corresponding wave element. The index a will be clipped to the valid range for wave1d.
<code>wave2d[a][b]</code>	Where a and b are constants or local variables. Both indices will be clipped to the valid range in the corresponding dimension.
<code>wave3d[a][b][c]</code>	Where a , b , and c are constants or local variables. All three indices will be clipped to the valid range in the corresponding dimension.
<code>wave3d[][][a]</code>	Layer a from the 3D wave will be treated as a 2D matrix. The first and second bracket pairs must be empty. a must be a constant that will be clipped to the valid range of layers.
<code>wave3d[][][a,b]</code>	The expression is evaluated for all layers between layer a and layer b . The result is a 3D wave.
<code>wave3d[][][a,b,c]</code>	The expression is evaluated for layers starting with layer a and increasing the layer number up to layer b using increments c . a , b , and c must be constants. Layers are clipped to the valid range and c must be a positive integer.

MatrixOP does not support expressions that include the same 3D wave on both sides of the expressions. For example, the expression

```
MatrixOP/O wave3D=wave3D+A
```

is not permitted. You can also use waves of any dimensions in the standard numerical functions. For example:

```
Make/O/N=128 wave1d=x
MatrixOP/O outWave=powR(wave1d,2)
```

Flags

<code>/C</code>	Provides a complex wave reference for the wave on the left hand side of the equation.
<code>/NTHR=n</code>	Sets the number of threads used to compute the results for 3D waves. Each thread computes the results for a single layer of the input. By default $n=0$ and the calculations are preformed by the main thread. For $n=1$ the operation uses as many threads as the number of processors on your computer. Higher values of n may or may not improve performance.
<code>/O</code>	Overwrites <i>destWave</i> if it already exists.
<code>/S</code>	Saves wave properties in output wave, e.g., units and wave note.

Details

MatrixOP does not support wave scaling, it does not support the standard p , q , r , s , t or x , y , z , and it does not support operator combinations of the form $+=$. The operation works only on 1D and 2D numerical waves.

You can use any combination of data types for operands. In particular, you can mix between real and complex types without having to worry about /C declarations for complex waves. MatrixOP determines the appropriate output data type at runtime.

When considering operator precedence, the first rule about operator precedence is that when in doubt, use parentheses. Otherwise, operation precedence is as indicated in the table above. When operators have the same precedence, execution associativity is from right to left.

When using MatrixOP, simple matrix operations execute approximately 20-30 times faster than normal Igor syntax. In most situations MatrixOP is faster than FastOP. It is important to note that usually you will find the best performance for single or double precision data types, so unless there is a severe memory restriction, it is advantageous to convert integer calculations to single precision floating point before performing any operations.

Examples

The following matrices are used in the examples:

```
Make/O/N=(3,3) r1=x, r2=y
```

Matrix addition and matrix multiplication by a scalar:

```
MatrixOP/O outWave = r1+r2-3*r1
```

Using the matrix Identity function:

```
MatrixOP/O outWave = Identity(3) x r1
```

Create a persisting identity matrix for another calculation:

```
MatrixOP/O id4 = Identity(4)
```

Using the Trace function:

```
MatrixOP/O outWave = (Trace(r1)*identity(3) x r1)-3*r1
```

Using matrix inverse function Inv() with matrix multiplication:

```
MatrixOP/O outWave = Inv(r2) x r2
```

Using the determinant function Det():

```
MatrixOP/O outWave = Det(r1)+Det(r2)
```

Using the Transpose postfix operator:

```
MatrixOP/O outWave = r1^t+(r2-r1)^t-r2^t
```

Using a mix of real and complex data:

```
Variable/C complexVar = cmplx(1,2)
```

```
MatrixOP/O outWave = complexVar*r2 - Cmplx(2,4)*r1
```

Hermitian transpose operator:

```
MatrixOP/O outWave = Trace(complexVar*r2)^h -Trace(cmplx(2,4)*r1)^h
```

In-place operation and conversion to complex:

```
MatrixOP/O r1 = r1*cmplx(1,2)
```

Image filtering using 2D spatial filter filterWave:

```
MatrixOP/O filteredImage=IFFT(FFT(srcImage,2)*filterWave,3)
```

Positive shift:

```
Make/O w={0,1,2,3,4,5,6}
```

```
MatrixOP/O w=shiftVector(w,2,77)
```

```
Print w
```

```
// w[0]= {77,77,0,1,2,3,4}
```

Negative shift:

```
Make/O w={0,1,2,3,4,5,6}
```

```
MatrixOP/O w=shiftVector(w,(-2),77)
```

```
Print w
```

```
// w[0]= {2,3,4,5,6,77,77}
```

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

The **FastOp** operation and **p2rect** and **r2polar** functions.

MatrixRank

matrixRank(matrixWaveA [, conditionNumberA])

The matrixRank function returns the rank of *matrixWaveA* subject to the specified condition number.

The matrix is not considered to have full rank if its condition number exceeds the specified *conditionNumberA*.

If the optional parameter *conditionNumberA* is not specified, Igor Pro uses the value 10^{20} .

matrixRank supports real and complex single precision and double precision numeric wave data types.

The value of *conditionNumberA* should be large enough but taking into account the accuracy of the numerical representation given the numeric data type.

If there are any errors the function returns NaN.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixSchur

MatrixSchur [/Z] srcMatrix

The MatrixSchur operation computes for an N-by-N real nonsymmetric *srcMatrix*, the eigen values, the real Schur form T, and, the matrix of Schur vectors Z which gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Flags

/Z No error reporting.

Details

The operation creates:

M_A	Matrix containing the Schur form T.
M_V	Matrix containing the orthogonal matrix Z of the Schur vectors.
W_REigenValues	
W_IEigenValues	Waves containing the real and imaginary parts of the eigen values when <i>srcMatrix</i> is a real wave. If <i>srcMatrix</i> is complex, the eigen values are stored in W_eigenValues.

The variable V_flag is set to 0 when there is no error; otherwise it contains the LAPACK error code.

Examples

You can test this operation for an N-by-N source matrix srcWave:

```
MatrixSchur srcWave
Duplicate M_V M_VT           // for the transpose
MatrixTranspose M_VT
MatrixMultiply M_V,M_A,M_VT
Edit M_Product                // compare the result with srcWave
```

Matrix Math Operations on page III-139 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixSolve

MatrixSolve method, matrixA, vectorB

The MatrixSolve operation was superseded by MatrixLLS and is included for backward compatibility only.

Used to solve matrix equation $Ax=b$ using the method of your choice. Choices for *method* are:

MatrixSVBkSub

<i>method</i>	Solution Method
GJ	Gauss Jordan.
LU	LU decomposition.
SV	Singular Value decomposition.

Details

The array *b* can be a matrix containing a number of *b* vectors and the output matrix *M_x* will contain a corresponding set of solution vectors.

V_flag is set to zero if success, 1 if singular matrix using GJ or LU and 1 if SV fails to converge.

For normal problems you should use LU. GJ is provided only for completeness and has no practical use.

When using SV, singular values smaller than 10^{-6} times the largest singular value are set to zero before back substitution.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also

The **MatrixLLS** operation. **Matrix Math Operations** on page III-139 for more about Igor's matrix routines.

MatrixSVBkSub

MatrixSVBkSub *matrixU*, *vectorW*, *matrixV*, *vectorB*

The MatrixSVBkSub operation does back substitution for SV decomposition.

Details

Used to solve matrix equation $Ax=b$ after you have performed an SV decomposition.

Feed this routine the *M_U*, *W_W* and *M_V* waves from **MatrixSVD** along with your right-hand-side vector *b*. The solution vector *x* is returned as *M_x*.

The array *b* can be a matrix containing a number of *b* vectors and the *M_x* will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixSVD

MatrixSVD [*flags*] *matrixWave*

The Matrix SVD operation uses the singular value decomposition algorithm to decompose an *MxN* *matrixWave* into a product of three matrices. The default decomposition is into *MxM* wave *M_U*, $\min(M,N)$ wave *W_W* and *NxN* wave *M_VT*.

Flags

/B Assures backwards compatibility with the old version (Igor Pro 3) of MatrixSVD. This option creates the variable *V_SVConditionNumber* and the *M_V* matrix. None of the other flags will have an effect when */B* is specified. The decomposition is such that:

$$U^*W^*V^T = \text{matrixWave}$$

U: *MxN* column-orthonormal matrix.

W: *NxN* diagonal matrix of positive singular values.

V: *NxN* orthonormal matrix.

/O Overwrites *matrixWave* with the first columns of *U*. Use this flag to if you need to conserve memory. See also related settings of */U* and */V*.

/U = UMatrixOptions

UMatrixOptions can have the following values:

0: All cols of *U* are returned in the wave *M_U* (default).

1: The first $\min(m,n)$ columns of *U* are returned in the wave *M_U*.

2: The first $\min(m,n)$ columns of *U* overwrite *matrixWave* (*/O* must be specified).

3: No columns of U are computed.

/V=VMatrixOptions
VMatrixOptions can have the following values:

0: All rows of V^T are returned in the wave *M_VT* (default).
 1: The first min(m,n) rows of V^T are returned in the wave *M_VT*.
 2: The first min(m,n) rows of V^T are overwritten on *matrixWave* (*/O* must be specified).
 3: No rows of V^T are computed.

/Z
 No error reporting.

Details

The singular value decomposition is computed using LAPACK routines. The diagonal elements of matrix W are returned as a 1D wave named *W_W*. If */B* is used *W_W* will have N elements. Otherwise the number of elements in *W_W* is min(M,N).

The matrix V is returned in a matrix wave named *M_V* if */B* is used otherwise the transpose V^T is returned in the wave *M_VT*.

If */B* is used, the variable *V_SVConditionNumber* is set to the condition number of the input matrix A. The condition number is the ratio of the largest singular value to the smallest.

All output objects are created in the current data folder.

The variable *V_flag* is set to zero if the operation succeeds. It is set to 1 if the algorithm fails to converge.

Example

```
Make/O/D/N=(10,20) A=gnoise(10)
MatrixSVD A
MatrixOP/O diff=abs(A-(M_U x DiagRC(W_W,10,20) x M_VT))
Print sum(diff,-inf,inf)
```

See Also

The **MatrixOP** operation for more efficient matrix operations.

Matrix Math Operations on page III-139 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixTrace

matrixTrace(*dataMatrix*)

The *matrixTrace* function calculates the trace (sum of diagonal elements) of a square matrix. *dataMatrix* can be of any numeric data type.

If the matrix is complex, it returns the sum of the magnitudes of the diagonal elements.

See Also

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

MatrixTranspose

MatrixTranspose [*/H*] *matrix*

The *MatrixTranspose* operation Swaps rows and columns in *matrix*.

Does not take complex conjugate if data are complex. You can do that as a follow-on step.

Swaps row and column labels, units and scaling.

This works with text as well as numeric waves. If the matrix has zero data points, it just swaps the row and column scaling.

Flags

/H Computes the Hermitian conjugate of a complex wave.

See Also

The **MatrixOP** operation for more efficient matrix operations.

Matrix Math Operations on page III-139 for more about Igor's matrix routines.

max

max

max(*num1*, *num2*)

The max function returns the more positive of *num1* and *num2*.

See Also

The **min** function.

mean

mean(*waveName* [, *x1*, *x2*])

The mean function returns the arithmetic mean of the wave for points from $x=x1$ to $x=x2$.

Details

If *x1* and *x2* are not specified, they default to $-\infty$ and $+\infty$, respectively.

The wave values from *x1* to *x2* are summed, and the result divided by the number of points in the range.

The X scaling of the wave is used only to locate the points nearest to $x=x1$ and $x=x2$. To use point indexing, replace *x1* with `pnt2x(waveName,pointNumber1)`, and a similar expression for *x2*.

If the points nearest to *x1* or *x2* are not within the point range of 0 to `numpts(waveName)-1`, mean limits them to the nearest of point 0 or point `numpts(waveName)-1`.

If any values in the point range are NaN, mean returns NaN.

Unlike the area function, reversing the order of *x1* and *x2* does *not* change the sign of the returned value.

Examples

```
Make/O/N=100 data;SetScale/I x 0,Pi,data
```

```
data=sin(x)
```

```
Print mean(data,0,Pi)           // the entire point range, and no more
```

```
Print mean(data)                // same as -infinity to +infinity
```

```
Print mean(data,Inf,-Inf)       // +infinity to -infinity
```

The following is printed to the history area:

```
·Print mean(data,0,Pi)           // the entire point range, and no more  
  0.630201
```

```
·Print mean(data)                // same as -infinity to +infinity  
  0.630201
```

```
·Print mean(data,Inf,-Inf)       // +infinity to -infinity  
  0.630201
```

See Also

The figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the **Details** section of the **faverage** function.

Menu

Menu *menuNameStr* [, *hideable*]

The Menu keyword introduces a menu definition. You can use this to create your own menu, or to add items to a built-in Igor menu. Use the optional *hideable* keyword to make the menu hideable using **HideIgorMenus**. See Chapter IV-5, **User-Defined Menus** for further information.

min

min(*num1*, *num2*)

The min function returns the more negative of *num1* and *num2*.

See Also

The **max** function.

mod

mod(*num*, *div*)

The mod function returns the remainder when *num* is divided by *div*.

The mod function will give unexpected results when *num* or *div* is fractional. For example:

```
Print/D mod(0.3,0.05)
```

prints
2.77555756156289e-17

This is because the numbers 0.3 and 0.05 can not be precisely represented by a finite precision binary number.

modDate

modDate (waveName)

The modDate function returns the modification date/time of the wave.

Details

The returned value is a double precision Igor date/time value, which is the number of seconds from 1/1/1904. It returns zero for waves created by versions of Igor prior to 1.2, for which no modification date/time is available.

See Also

The **Secs2Date** and **Secs2Time** functions.

Modify

Modify

We recommend that you use **ModifyGraph**, **ModifyTable**, **ModifyLayout**, or **ModifyPanel** rather than **Modify**. When interpreting a command, Igor treats the **Modify** operation as **ModifyGraph**, **ModifyTable**, **ModifyLayout** or **ModifyPanel**, depending on the target window. This does not work when executing a user-defined function.

ModifyContour

ModifyContour [/W=winName] *contourInstanceName*, keyword=value
[, keyword=value...]

ModifyContour modifies the number, Z value and appearance of the contour level traces associated with *contourInstanceName*.

contourInstanceName is a name derived from the name of the wave that provides the Z data values. It is usually just the name of the wave, but may have #1, #2, etc. added to it in the unlikely event that the same Z wave is contoured more than once in the same graph.

contourInstanceName can also take the form of a null name and instance number to affect the instanceth contour plot. That is,

ModifyContour ''#1

modifies the appearance of the second contour plot in the top graph, no matter what the contour plot names are. Note: Two single quotes, not a double quote.

contourInstanceName can also take the form of a null name and instance number to affect the instanceth contour plot. That is, **ModifyContour** ''#1 modifies the appearance of the second contour plot in the top graph, no matter what the contour plot names are. Note: two single quotes, not a double quote.

The number of contour level traces and their Z values are set by the *autoLevels*, *manLevels*, and *moreLevels* keywords, described in the **Parameters** section. Normally, you will use either *autoLevels* or *manLevels*, and then optionally generate additional levels using *moreLevels*.

Parameters

Each parameter has the syntax

keyword = *value*

and is applied to all of the contour level traces associated with *contourInstanceName*.

To modify an individual contour level trace, use **ModifyGraph**.

autoLevels= {*minLevel*, *maxLevel*, *numLevels*}

Controls automatic determination of contour levels.

If *numLevels* is zero, no automatic levels are generated. If it is nonzero, it specifies the desired number of automatic contour levels.

- minLevel* specifies the minimum contour level and *maxLevel* specifies the maximum contour level. The values that you specify are an approximate guide for Igor to use in determining the actual levels.
- However, if *minLevel* or *maxLevel* is * (asterisk symbol), Igor uses the minimum or maximum value of the Z data for the corresponding contour level.
- Using the *autoLevels* keyword cancels the effect of any previous *autoLevels* or *manLevels* keyword.
- When you first append a contour plot to a graph, default contour levels are generated by the default setting *autoLevels*={*,*,11}.
- boundary=b** Draws an outline around the XY domain of the contour data. For a matrix, this draws a rectangle showing the minimum and maximum X and Y values. For XYZ triples, the outline is a polygon enclosing the outside edges of the Delaunay Triangulation. Like the contour lines, the boundary is drawn using a graph trace, whose name is usually something like "contourInstanceName = boundary".
- b*=0: Hides the data boundary (default).
- b*=1: Shows the data boundary.
- cIndexLines= *matrixWave*** Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified matrix wave.
- matrixWave* is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than 3 columns. Any extra columns are ignored.)
- The color for a the contour line at *Z=z* is determined by finding the RGB values in the row of *matrixWave* whose scaled X index is *z*. In other words, the red value is *matrixWave*(*z*)[0], the green value is *matrixWave*(*z*)[1] and the blue value is *matrixWave*(*z*)[2].
- If *matrixWave* has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for *Z*=0, row 1 contains the color for *Z*=1, etc.
- If you use *cIndexLines*, you must not use *ctabLines* or *rgbLines* in the same command.
- ctabLines={*zMin*, *zMax*, *ctName*, *mode*}** Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified color table. *zMin* is mapped to the first color in the color table. *zMax* is mapped to the last color. Z values between the min and max are linearly mapped to the colors between the first and last in the color table.
- You can enter * (an asterisk) for *zMin* and *zMax*, which uses the minimum and maximum Z values of the data. The default is {*,*,Rainbow}.
- Set parameter *mode* to 1 to reverse the color table; zero or missing does not reverse the color table.
- ctName* can be any color table name returned by the **CTabList** function, such as Grays or Rainbow. Also see **Color Tables** on page II-327.
- If you use *ctabLines*, you must not use *cIndexLines* or *rgbLines* in the same command.
- interpolate=i** XYZ contours can be interpolated to increase the apparent resolution, resulting in smoother contour lines.
- This keyword is allowed only for XYZ contours, created by **AppendXYZContour**.
- i*=0: Linear interpolation (default). This means that only the original Delaunay triangulation generates contour lines.
- i*=1: Four times the resolution generates a smoother set of contour lines. As expected, this takes longer than Linear interpolation.
- i*=2: Sixteen times the resolution generates a much smoother set of contour lines. This is rather slow....
- The interpolate parameter can be up to 8. Each time you increase *i* by one, you quadruple the apparent resolution and get smoother contour lines at the expense of computation time. Values of *i* greater than two are impractical because of the computation time required.
- labelBkg=(*r*, *g*, *b*)** Sets the background color for all contour level labels to the specified color. *r*, *g*, and *b* are values from 0 to 65535.

labelBkg= <i>b</i>	<p><i>b</i>=0: Uses each label's individual background color, as set via the Modify Annotation dialog.</p> <p><i>b</i>=1: Makes all contour level labels transparent.</p> <p><i>b</i>=2: Uses the plot area background color as the label background color (default).</p> <p><i>b</i>=3: Uses the window background color as the label background color.</p>
labelDigits= <i>d</i>	<i>d</i> is the number of digits after the decimal point when using labelFormat=3 or labelFormat=5.
labelFont= <i>fontName</i>	Default; specifies the font to use for contour level labels. If you pass "" for <i>fontName</i> , it will use the graph font (set via the Modify Graph dialog) for contour labels.
labelFormat= <i>l</i>	<p>Controls the formatting of contour labels. See the printf operation for a discussion of formatting.</p> <p><i>l</i>=0: Uses general format that is suitable for most data. This is equivalent to "%<sigDigits>g".</p> <p><i>l</i>=1: Uses integer format, equivalent to "%<sigDigits>d".</p> <p><i>l</i>=3: Uses fixed point format, equivalent to "%<decimalDigits>f".</p> <p><i>l</i>=5: Uses exponential format, equivalent to "%<decimalDigits>e".</p>
labelFSize= <i>s</i>	Specifies the font size of contour labels in points. For example, use labelSize=12 for 12 point type. The default value is 0, which chooses the size automatically based on the size of the graph.
labelFStyle= <i>n</i>	<p><i>n</i> is a binary coded number with each bit controlling one aspect of the font style for the contour level labels. The default is 0, plain text.</p> <p>bit 0: Bold.</p> <p>bit 1: Italic.</p> <p>bit 2: Underline.</p> <p>bit 3: Outline (<i>Macintosh only</i>).</p> <p>bit 4: Shadow (<i>Macintosh only</i>).</p> <p>bit 5: Condensed (<i>Macintosh only</i>).</p> <p>bit 6: Extended (<i>Macintosh only</i>).</p> <p>See Setting Bit Parameters on page IV-11 for details about bit settings.</p>
labelHV= <i>hv</i>	<p>Specifies the contour label orientation.</p> <p><i>hv</i>=0: Horizontal contour level labels.</p> <p><i>hv</i>=1: Vertical contour level labels.</p> <p><i>hv</i>=2: Horizontal or vertical contour level labels, depending on the slope of the contour line (default).</p>
labelRGB=(<i>r</i> , <i>g</i> , <i>b</i>)	Sets the text color for all contour level labels. <i>r</i> , <i>g</i> , and <i>b</i> are values from 0 to 65535. The default is black, labelRGB=(0,0,0).
labels= <i>l</i>	<p><i>l</i>=0: Hides contour level labels.</p> <p><i>l</i>=1: Leaves any contour level labels in place but stops updating them and stops generation of new labels.</p> <p><i>l</i>=2: Generates or updates labels for the existing contour levels and window size when the command executes, but disables further updating of labels when window size or contour plot changes. This is the recommended setting if updating the labels takes long enough to annoy you.</p> <p><i>l</i>=3: Default; generates labels for all contour levels whenever the contoured data changes but not when the window size changes. If you resize the graph, the labels may overlap or be too sparse.</p> <p><i>l</i>=4: Generates labels for all contour levels whenever the contoured data, contour levels, axis range, or the graph size changes. (Actually, there are too many causes to list here. If all this update annoys you, use labels=2 "update once, now".)</p>
labelSigDigits= <i>d</i>	<i>d</i> is the number of significant digits when labelFormat=0 is used.

ModifyContour

- manLevels=** {*firstLevel*, *increment*, *numLevels*}
- Explicitly specifies contour levels. ModifyContour will generate *numLevels* contour levels, evenly spaced starting from *firstLevel* and stepping by *increment*.
- manLevels** cancels the effect of any previous **manLevels** or **autoLevels** settings.
- manLevels=** *manLevelsWave*
- Explicitly specifies contour levels. ModifyContour will generate contour levels at the values in *manLevelsWave*.
- manLevels** cancels the effect of any previous **manLevels** or **autoLevels** settings.
- moreLevels=** {*level*, *level* ...}
- Explicitly specifies contour levels. ModifyContour will generate a contour trace for each of the listed levels. The maximum number of levels that you can specify in a single command is the 50. However, you can concatenate any number of ModifyContour **moreLevels** commands. **moreLevels** adds levels in addition to any specified by **manLevels** or **autoLevels**. It does not override other parameters.
- moreLevels=0:** Removes all levels generated by previous **moreLevels** settings.
- nullValue=zValue** Treat blanks (NaNs) in the data as if they were the specified *zValue*.
- The **nullValue** keyword is allowed only for XYZ contours, created by **AppendXYZContour**.
- nullValueAuto** Treats blanks (NaNs) in the data as if they were the minimum value in the Z wave minus 1.
- The **nullValueAuto** keyword is allowed only for XYZ contours, created by **AppendXYZContour**.
- rgbLines=(*r*, *g*, *b*)** Specifies red, green, and blue values for all contour lines. *r*, *g*, and *b* are values from 0 to 65535.
- If you use **rgbLines**, you must not use **cIndexLines** or **ctabLines** in the same command.
- triangulation=t** Draws the Delaunay Triangulation. As part of the XYZ contouring algorithm, the XY domain is subdivided into triangles in a process called Delaunay Triangulation. Like the contour lines, the triangulation is drawn using a graph trace, whose name is usually something like "contourInstanceName =triangulation".
- The **triangulation** keyword is allowed only for XYZ contours, created by **AppendXYZContour**.
- t=0:** Hides the Delaunay triangulation (default).
- t=1:** Shows the Delaunay triangulation.
- update=u** Sets the type of updating of contour traces when the data or contour settings change.
- u=0:** Turns off dynamic updates, which might be advisable if updates take a long time.
- u=1:** Updates the contours only once, or until you next execute an **update=1** command.
- u=2:** Updates are automatic (default).
- u=3:** Marks the contour plot as having been updated once (**u=1**) already. This option is used in recreation macros to prevent an extra redraw of a graph saved with **u=1** update mode in effect.
- If you use it in a command, the result is similar to **u=0**, but the Modify Contour Appearance dialog will automatically select "update once, now" from the Update Contours pop-up menu.
- xymarkers=x** **x=0:** Hides markers showing XY coordinates of the Z data (default).
- x=1:** Displays markers showing XY coordinates of Z data. Initially, this uses marker number zero. You can change this using the Modify Trace Appearance dialog.

Flags

- /W=winName** Applies to contours in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

AppendMatrixContour and AppendXYZContour.

ModifyControl

ModifyControl [/Z] *ctrlName* [, **keyword** = *value*]

The ModifyControl operation modifies the named control. ModifyControl works on any kind of existing control. To modify multiple controls, use **ModifyControlList**.

Parameters

ctrlName specifies the name of the control to be created or changed. The control must exist.

win=winName Specifies the window or subwindow containing the named control. Without the keyword, the control is expected to exist in the target window or subwindow.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

Use ModifyControlList to move, hide, disable, or change the appearance of a control without regard to its kind

Most, but not all, control keywords work with ModifyControl. In general, keywords that are common to most controls will work. See the individual control command for keyword details.

Example

Here is a **TabControl** procedure that shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are.

The “trick” here is that all controls that are to be shown within particular tab *n* have been assigned names that end with “_tab*n*” such as “_tab0” and “_tab1”:

```
Function TabProc(ctrlName,tabNum) : TabControl
    String ctrlName
    Variable tabNum
    String curTabMatch= "_tab"+num2istr(tabNum)
    String controls= ControlNameList("")
    Variable i, n= ItemsInList(controls)
    for(i=0; i<n; i+=1)
        String control= StringFromList(i, controls)
        Variable isInATab= stringmatch(control,"*_tab*")
        if( isInATab )
            Variable show= stringmatch(control,curTabMatch)
            ControlInfo $control // gets V_disable
            if( show )
                V_disable= V_disable & ~0x1 // clear the hide bit
            else
                V_disable= V_disable | 0x1 // set the hide bit
            endif
            ModifyControl $control disable=V_disable
        endif
    endfor
    return 0
End
```

Here is a panel macro that creates a TabControl using TabProc ():

```
Window TabbedPanel() : Panel
    PauseUpdate; Silent 1 // building window...
    NewPanel /W=(381,121,614,237) as "Tab Demo"
    TabControl tab, pos={12,9},size={205,91},proc=TabProc,tabLabel(0)="Tab 0"
    TabControl tab, tabLabel(1)="Tab 1",value= 0
    Button button_tab0, pos={54,39},size={110,20},disable=2
    Button button_tab0, title="Button in Tab0"
    Button button_tab1, pos={54,63},size={110,20},disable=1
    Button button_tab1, title="Button in Tab1"
    CheckBox check1_tab1, pos={51,41}, size={117,14}, disable=1, value= 1
    CheckBox check1_tab1, proc=Tab1CheckProc, title="Enable Button in Tab 1"
    CheckBox check0_tab0, pos={51,73}, size={117,14}, proc=Tab0CheckProc,
```

ModifyControlList

```
        CheckBox check0_tab0, value= 0, title="Enable Button in Tab 0"  
EndMacro
```

Here are the action procedures which enable or disable the buttons:

```
Function Tab1CheckProc(ctrlName,enableButton) : CheckBoxControl  
    String ctrlName  
    Variable enableButton  
    ModifyControl button_tab1, disable=(enableButton ? 0 : 2 )  
End  
Function Tab0CheckProc(ctrlName,enableButton) : CheckBoxControl  
    String ctrlName  
    Variable enableButton  
    ModifyControl button_tab0, disable=(enableButton ? 0 : 2 )  
End
```

Click on “Tab 0” and “Tab 1” to run TabProc.

See Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Related functions **ModifyControlList** and **ControlNameList**.

The **Button**, **Chart**, **CheckBox**, **GroupBox**, **ListBox**, **PopupMenu**, **SetVariable**, **Slider**, **TabControl**, **TitleBox**, and **ValDisplay** controls.

ModifyControlList

ModifyControlList [/Z] *listStr* [, keyword = value]...

The **ModifyControlList** operation modifies the control(s) named in the *listStr* string expression. **ModifyControlList** works on any kind of existing control.

Parameters

listStr is a semicolon-separated list of name(s) in a string expression. The expression can be an explicit list of control names such as "button0;checkbox1;" or it can be any string expression such as a call to the **ControlNameList** string function:

```
ModifyControlList ControlNameList("",";","*_tab0") disable=1
```

The control(s) must exist.

Use the *win=winName* keyword to specify which window or subwindow the named control is in. Without the keyword, the control is expected to exist in the target window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

Use **ModifyControlList** to move, hide, disable, or change the appearance of multiple controls without regard to their kind.

Most, but not all, control keywords work with **ModifyControlList**. In general, keywords that are common to most controls will work. See the individual control command for keyword details.

If *listStr* contains the name of a nonexistent control, an error is generated.

if *listStr* is " " (or any list element in *listStr* is " "), it is ignored and no error is generated.

Example

Here is the **TabControl** procedure example from **ModifyControl** rewritten to use **ModifyControlList**. It shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are, but the code is simpler. This method does not, however, preserve the enable bit when a control is hidden.

The “trick” here is that all controls that are to be shown within particular tab *n* have been assigned names that end with “_tab*n*” such as “_tab0” and “_tab1”:

```
Function TabProc2(ctrlName,tabNum) : TabControl  
    String ctrlName  
    Variable tabNum  
    String controlsInATab= ControlNameList("",";","*_tab*")
```

```
String curTabMatch= "*" tab"+num2istr(tabNum)
String controlsInCurTab= ListMatch(controlsInATab, curTabMatch)
String controlsInOtherTabs=ListMatch(controlsInATab,"!" +curTabMatch)

ModifyControlList controlsInOtherTabs disable=1           // hide
ModifyControlList controlsInCurTab disable=0             // show

return 0
End
```

Here is a panel macro that creates a TabControl using TabProc2():

```
Window TabbedPanel2() : Panel
    PauseUpdate; Silent 1                                // building window...
    NewPanel /W=(35,208,266,374) as "Tab Demo"
    TabControl tab,pos={12,9},size={205,140},proc=TabProc2
    TabControl tab,tabLabel(0)="Tab 0"
    TabControl tab,tabLabel(1)="Tab 1",value= 0
    Button button_tab0,pos={26,43},size={110,20},title="Button in Tab0"
    Button button2_tab0,pos={26,74},size={110,20},title="Button in Tab0"
    Button button3_tab0,pos={26,106},size={110,20},title="Button in Tab0"
    Button button_tab1,pos={85,43},size={110,20},title="Button in Tab1"
    Button button2_tab1,pos={85,75},size={110,20},title="Button in Tab1"
    Button button3_tab1,pos={84,108},size={110,20},title="Button in Tab1"
    ModifyControlList ControlNameList("",";","*_tab1") disable=1
EndMacro
```

Click on “Tab 0” and “Tab 1” to run TabProc.

ModifyFreeAxis

ModifyFreeAxis [/W=*winName*] *axisName*, *master=masterName*
[, *hook=funcName*]

The ModifyFreeAxis operation designates the free axis (created with **NewFreeAxis**) to follow a controlling axis from which it gets axis range and units information. The free axis updates whenever the controlling axis changes. The axis limits and units can be modified by a user hook function.

Parameters

axisName is the name of the free axis (which must have been created by **NewFreeAxis**).

masterName is the name of the master axis controlling *axisName*.

funcName is the name of the user function that modifies the limits and units properties of the axis. If *funcName* is \$ " " , the named hook function is removed.

Flags

/W=*winName* Modifies *axisName* in the named graph window or subwindow. If /W is omitted the command affects the top graph window or subwindow.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The free axis can also be designated to call a user-defined hook function that can modify limits and units properties of the axis. The hook function must be of the following form:

```
Function MyAxisHook(info)
    STRUCT WMAxisHookStruct &info
    <code to modify graph units or limits>
    return 0
End
```

ModifyGraph (general)

where `WMAxisHookStruct` is a built-in structure with the following members:

WMAxisHookStruct Structure Members

Member	Description
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.
<code>char axName[MAX_OBJ_NAME+1]</code>	Name of the axis.
<code>char mastName[MAX_OBJ_NAME+1]</code>	Name of controlling axis or nil.
<code>char units[MAX_UNITS+1]</code>	Axis units. User modifiable.
<code>double min, max</code>	Axis range minimum and maximum values. User modifiable.

The constants used to size the `char` arrays are internal to Igor and are subject to change in future versions.

The hook function is called when refreshing axis range information (generally early in the update of a graph). Your hook must never kill a graph or an axis.

See Also

The **SetAxis**, **KillFreeAxis**, and **NewFreeAxis** operations.

The **ModifyGraph (axes)** operation for changing other aspects of a free axis.

ModifyGraph (general)

ModifyGraph [/W=*winName*/Z] **key=value** [, **key=value**]...

The **ModifyGraph** operation modifies the target or named graph. This section of **ModifyGraph** relates to general graph window settings.

Parameters

<code>expand=<i>e</i></code>	Specifies the onscreen expansion (or magnification) factor of a graph. <i>e</i> may be zero or 0.125 to 8 times expansion. Graph magnification affects only base graphs (not subwindowed graphs), and it affects only the onscreen display; it has no effect on graph exporting or printing. When magnification changes, the graph window will automatically resize except for negative values, which are used in recreation macros where the size is already correct.
<code>frameInset=<i>i</i></code>	Specifies the number of pixels by which to inset the frame of the graph subwindow.
<code>frameStyle=<i>f</i></code>	Specifies the frame style for a graph subwindow. <i>f</i> =0: None. <i>f</i> =1: Single. <i>f</i> =2: Double. <i>f</i> =3: Triple. <i>f</i> =4: Shadow. <i>f</i> =5: Indented. <i>f</i> =6: Raised. <i>f</i> =7: Text well. The last three styles are fake 3D and will look good only if the background color of the enclosing space and the graph itself is a light shade of gray.
<code>gfMult=<i>f</i></code>	Multiplies font and marker size by <i>f</i> percent. Clipped to between 25% and 400%; it is applied after all other font and marker size calculations.
<code>gFont=<i>fontStr</i></code>	Specifies the name of the default font for the graph, overriding the normal default font. The normal default font for a subgraph is obtained from its parent while a base graph uses the value set by the DefaultFont operation.
<code>gfSize=<i>gfs</i></code>	Sets the default size for text in the graph. Normally, the default size for text is proportional to the graph size; <i>gfSize</i> will override that calculation as will the <i>gfRelSize</i> method. Use a value of -1 to make a subgraph get its default font size from its parent.

<code>gfRelSize=pct</code>	Specifies the percentage of the graph size to use in calculating a default size for text in the graph. This overrides the normal method for setting default font size as a function of graph size. When used, the default marker size is set to one third the font size. Use a value of 0 to revert to the default method.
<code>gmSize=gms</code>	Sets the default size for markers in the graph. Use a value of -1 to make a subgraph get its default marker size from its parent.
<code>height=heightSpec</code>	Sets the height for the graph area. See the Examples .
<code>swapXY=s</code>	<p><code>s=0:</code> Normal orientation of X and Y axes.</p> <p><code>s=1:</code> Swap X and Y values to plot Y coordinates versus the horizontal axes and X coordinates versus the vertical axes. The effect is similar to mirroring the graph about the lower-left to upper-right diagonal.</p>
<code>useComma=uc</code>	<p><code>uc=0:</code> Use period as decimal separator and comma as thousands separator (default) when displaying numbers in graph labels and annotations.</p> <p><code>uc=1:</code> Use comma as decimal separator and period as the thousands separator. This does not alter the presentation of numbers in <code>\{expression\}</code> constructs in annotations.</p>
<code>useLongMinus=m</code>	Uses a normal (<code>m=0</code> ; default) or long dash (<code>m=1</code>) for the minus sign.
<code>width=widthSpec</code>	Sets the width of the graph area. See the examples.

Flags

<code>/W=winName</code>	<p>Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.</p> <p>When identifying a subwindow with <i>winName</i>, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.</p>
<code>/Z</code>	Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Examples

The following code creates a graph where all the text expands and contracts directly in relation to the window size:

```
Make jack=sin(x/8);display jack
ModifyGraph mode=4,marker=8,gfRelSize= 5.0
TextBox/N=text0/A=MC "Some \\Zr200big\\j0 and \\Zr050small\\j0\rtext"
```

The *widthSpec* and *heightSpecs* set the width and height mode for the top graph. The following examples illustrate how to specify the various modes.

<code>ModifyGraph width=0, height=0</code>	Set to auto height, width mode. The width, height of horizontal and vertical axes are automatically determined based on the overall size of the graph and other factors such as axis offset setting and effect of exterior textboxes. This is the normal, default mode.
<code>Variable n=72*5</code> <code>ModifyGraph width=n</code>	Five inches as points absolute width mode, horizontal axis width constrained to n points.
<code>ModifyGraph height=n</code>	Absolute height mode, n is in points. The height of the vertical axes is constrained to n points.
<code>Variable n=2</code> <code>ModifyGraph width={perUnit,n,bottom}</code>	Per unit width mode. The width of the horizontal axes is n points times the range of the bottom axis.
<code>ModifyGraph height={Aspect,n}</code>	Aspect height mode, n = aspect ratio. The height of the vertical axes is n times the width of the horizontal axes.
<code>ModifyGraph width={Plan,n,bottom,left}</code>	Plan width mode. The width of the horizontal axes is n times the height of the vertical axes times range of the bottom axis divided by the range of the left axis.

ModifyGraph (traces)

ModifyGraph [/W=*winName*/Z] **key** [(*traceName*)] = *value*
[, **key** [(*traceName*)] = *value*]...

This section of **ModifyGraph** relates to modifying the appearance of wave “traces” in a graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters

Each *key* parameter may take an optional *traceName* enclosed in parentheses. Usually *traceName* is simply the name of a wave displayed in the graph, as in “**mode**(*myWave*)=4”. If “(*traceName*)” is omitted, all traces in the graph are affected. For instance, “**ModifyGraph** *lSize*=0.5” sets the lines size of all traces to 0.5 points.

For multiple trace instances, *traceName* is followed by the “#” character and instance number. For example, “**mode**(*myWave*#1)=4”. See **Instance Notation** on page IV-16.

A string containing a trace name can be used with the \$ operator to specify *traceName*. For example, **String** *MyTrace*="myWave#1"; **mode**(*\$MyTrace*)=4.

Though not shown in the syntax, the optional “(*traceName*)” may be replaced with “[*traceIndex*]”, where *traceIndex* is zero or a positive integer denoting the trace to be modified. “[0]” denotes the first trace appended to the graph, “[1]” denotes the second trace, etc. This syntax is used for style macros, in conjunction with the /Z flag.

The parameter descriptions below omit the optional “(*traceName*)”. When using **ModifyGraph** from a user-defined function, be careful not to pass wave references to **ModifyGraph**. **ModifyGraph** expects trace names, not wave references. See **Trace Name Parameters** on page IV-60 for details.

arrowMarker=0

arrowMarker={*aWave*, *lineThick*, *headLen*, *headFat*, *posMode* [, *barbSharp*=*b*, *barbSide*=*s*, *frameThick*=*f*]}

Draws arrows instead of conventional markers at each data point in a wave. Arrows are not clipped to the plot area and will be drawn wherever a data point is within the plot area.

aWave contains arrow information for each data point. It is a two (or more) column wave containing arrow line lengths (in points) in column 0 and angles (in radians measured counterclockwise) in column 1. Zero angle is a horizontal arrow pointing to the right. If an arrow is below the minimum length of 4 points, a default marker is drawn.

You can change arrow markers into standard meteorological wind barbs by adding a column to *aWave* and giving it a column label of *windBarb*. Values are integers from 0 to 40 representing wind speeds up to 4 flags. Use positive integers for clockwise barbs and negative for the reverse. Use NaN to suppress the drawing. (See **Examples**.)

Additional columns may be supplied in *aWave* to control parameters on a point by point basis. These optional columns are specified by dimension label and not by specific column numbers. The labels are *lineThick*, *headLen*, and *headFat* that correspond to the same parameters listed above.

lineThick is the line thickness in points.

headLen is the arrow head length in points.

headFat controls the arrow fatness. It is the width of the arrow head divided by the length.

posMode specifies the arrow location relative to the data point.

posMode=0: Start at point.

posMode=1: Middle on point.

posMode=2: End at point.

In addition to the wave specification, *aWave* can also be the literal `_inline_` to draw lines and arrows between points on the trace (see **Examples**). If *aWave* is `_inline_`, *posMode* values are:

posMode=0: Arrow at end.

posMode=1: Arrow in middle.

posMode=2: Arrow at start.

posMode=3: Arrow in middle pointing backwards.

Note: Arrow behavior as specified by *posMode* is different when you use a multicolumn wave vs. `_inline_` for *aWave*.

Optional parameters must be specified using *keyword = value* syntax and can only be appended after *posMode* in any order.

barbSharp is the continuously variable barb sharpness between -1.0 and 1. 0:

barbSharp=1: No barb; lines only.

barbSharp=0: Blunt (default).

barbSharp=-1: Diamond.

barbSide specifies which side of the line has barbs relative to a right-facing arrow:

barbSide=0: None.

barbSide=1: Top.

barbSide=2: Bottom.

barbSide=3: Both (default).

frameThick specifies the stroke outline thickness of the arrow in points. The default is *frameThick* = 0 for solid fill.

aWave can contain columns with data for each optional parameter using matching column names.

cmplxMode=*c* Display method for complex waves.

c=0: Default mode displays both real and imaginary parts (imaginary part offset by $dx/2$).

c=1: Real part only.

c=2: Imaginary part only.

c=3: Magnitude.

c=4: Phase (radians).

gaps=*g* *g*=0: No gaps (ignores NaNs).

g=1: Gaps (shows NaNs as gaps).

hBarNegFill=*n* Fill kind for negative areas if useNegPat is true. *n* is the same as for the *hbFill* keyword.

hbFill=*n* Sets the fill pattern.

n=0: No fill.

n=1: Erase.

n=2: Solid black.

n=3: 75% gray.

n=4: 50% gray.

n=5: 25% gray.

n= 6 through 77 selects one of the 72 fill patterns.

hideTrace=*h* Removes a trace from the graph display.

h=1: Hides the trace and removes it from autoscale calculations.

h=2: Hides the trace.

When using *h*=1 to hide a graph trace, the hidden trace symbol and following text in annotations are also hidden. The amount of hidden text is the lesser of: 1) the remaining text on the same line or 2) the text up to but not including another trace symbol "*\s (traceName)*".

lHair=*lh* Sets the hairline factor for traces printed on a PostScript® printer.

live=*lv* Turns Live Mode off (*lv*=0) or on (*lv*=1).

lSize=*l* Sets the line thickness, which can be fractional or zero, which hides the line.

ModifyGraph (traces)

lSmooth=*ls*

Sets the smoothing factor for traces printed on a PostScript® printer.

lStyle=*s*

Sets trace line style or dash pattern.

s=0 for solid lines. *s*=1 to *s*=17 for various dashed line styles.

marker=*n*

Sets marker type.

n=0 to 50 designates various markers if mode=3 or 4. Markers 0-44 are compatible with Igor Pro 4.

mask={*maskwave*,*mode*,*value*} or 0

Specifies individual points for display by comparing values in *maskWave* with *value* as specified by *mode*.

mode=0: Exclude if equal.

mode=1: Include if equal.

mode=2: Include if bitwise AND is true.

mode=3: Include if bitwise AND is false.

maskwave can be specified using subrange notation. The length of *maskwave* (or subrange) must match the size of specified trace's wave (or subrange.) Bitwise modes should be used with integer waves with the intent of using one mask wave with multiple traces. (See **Examples**.)

mode=*m*

Sets trace display mode.

m=0: Lines between points.

m=1: Sticks to zero.

m=2: Dots at points.

m=3: Markers.

m=4: Lines and markers.

m=5: Histogram bars.

m=6: Cityscape.

m=7: Fill to zero.

m=8: Sticks and markers.

mrkStrokeRGB=(*r*,*g*,*b*)

Specifies the color for marker stroked lines if useMrkStrokeRGB = 1. *r*, *g*, and *b* values are the amount of red, green, and blue in the color of the lines as an integer from 0 to 65535. The marker fill color continues to be set with the rgb=(*r*,*g*,*b*) or zColor={...} parameters.

Applies only to the nontext and nonarrow marker modes.

Use mrkStrokeRGB and useMrkStrokeRGB to put a colored outline around filled markers, such as marker=19:

useMrkStrokeRGB=0

useMrkStrokeRGB=1

Note: The stroke color of unfilled markers such as marker 8 is also affected by mrkStrokeRGB, but their fill color is only affected by the opaque parameter (and the opaque fill color is always white, so if you want a color-filled marker, don't use unfilled markers).

mrkThick= <i>t</i>	Sets the thickness of markers in points, which can be fractional.
msize= <i>m</i>	Specifies the marker size in points. <i>m</i> =0: Autosize markers. <i>m</i> >0: Sets marker size. <i>m</i> can be fractional, which will only make a difference when the graph is printed because fractional points can not be displayed on the screen.
mskip= <i>n</i>	Puts a marker on only every <i>n</i> th data point in Lines and Markers mode (mode=4). Useful for displaying many data points when you want to identify the traces with markers. The maximum value for <i>n</i> is 32767.
muloffset={ <i>mx,my</i> }	Sets the display multiplier for X (<i>mx</i>) and Y (<i>my</i>). The effective value for a given X or Y data point then becomes <i>muloffset</i> * <i>data</i> + <i>offset</i> . A value of zero means "no multiplier" — not multiply by zero.
negRGB=(<i>r, g, b</i>)	Specifies the color for negative areas if useNegRGB is 1. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color of the trace as an integer from 0 to 65535.
offset={ <i>x,y</i> }	Sets the display offset in horizontal (X) and vertical (Y) axis units.
opaque= <i>o</i>	Displays transparent (<i>o</i> =0) or opaque (<i>o</i> =1) markers.
plotClip= <i>p</i>	<i>p</i> =1 clips the trace by the operating system (not by Igor) to the plot rectangle. This trims overhanging markers and thick lines. On Windows, this may not be supported for certain printers or by certain applications when importing.
plusRGB=(<i>r, g, b</i>)	Specifies the color for positive areas if usePlusRGB is 1. <i>r</i> , <i>g</i> , and <i>b</i> specify the amount of red, green, and blue in the color of the trace as an integer from 0 to 65535.
quickdrag= <i>q</i>	<i>q</i> =0: Normal traces. <i>q</i> =1: Traces that can be instantly dragged without the normal one second delay. See Details section.
rgb=(<i>r,g,b</i>)	Specifies the amount of red, green, and blue (<i>r</i> , <i>g</i> , and <i>b</i>) in the color of the waves as an integer from 0 to 65535.
textMarker={< <i>char</i> or <i>wave</i> >,font,style,rot,just,xOffset,yOffset} or 0	Uses the specified character or text from the specified wave in place of the marker for each point in the trace. <p>If the first parameter is a quoted string or a string expression of the form "<i>strexpr</i>" in a user function, ModifyGraph uses the first three bytes of the string as the marker for all points (three bytes are provided mainly for multi-byte Asian fonts but can be used for 3 separate one byte characters). Otherwise, it interprets the first parameter as the name of a wave. If the wave is a text wave, it uses the value of each point in the text wave as the marker for the corresponding point in the trace. If the wave is a numeric wave, the value for each point is converted into text and the result is used as the marker for the corresponding point in the trace.</p> <p><i>xOffset</i> and <i>yOffset</i> are offsets in fractional points. Each marker will be drawn offset from the location of the corresponding point in the trace by these amounts.</p> <p><i>style</i> is a font style code as used with the ModifyGraph <i>fstyle</i> keyword.</p> <p><i>rot</i> is a text rotation in degrees. Legal values are 0, 90, 180, 270, and -90.</p> <p><i>just</i> is a justification code as used in the DrawText operation except the X and Y codes are combined as <i>y</i>*4+<i>x</i>. Use 5 for centered.</p>

ModifyGraph (traces)

	<p>The font size is 3*marker size. Note that marker size and color can be dynamically set via the <code>zColor</code> and <code>zmrkSize</code> keywords.</p>
<code>toMode=t</code>	<p>Modifies the behavior of the display modes as determined by the mode parameter.</p> <p><code>t=0</code>: Fill to zero.</p> <p><code>t=1</code>: Fill to next trace. Applies to Sticks to zero (mode=1), histogram bars (mode=5), and fill to zero (mode=7).</p> <p><code>t=2</code>: Add the current trace's Y values to the next trace's Y values. Works with all display modes.</p> <p><code>t=3</code>: Stack on next and is the same as <code>t=2</code> except that the added value is clipped to zero. Works with all display modes.</p> <p><code>t=-1</code>: This mode is used only with category plots and means "keep with next" (i.e., put in the same subcategory as the next trace). It is used for special effects only.</p>
<code>useMrkStrokeRGB=u</code>	<p>If <code>u=1</code> then marker stroked lines use the color specified by the <code>mrkStrokeRGB</code> keyword. The marker fill color continues to be set with the <code>rgb=(r,g,b)</code> or <code>zColor={...}</code> parameters. Applies only to the nontext and nonarrow marker modes.</p> <p>If <code>u=0</code> then the marker stroked line colors are set with the <code>rgb=(r,g,b)</code> or <code>zColor={...}</code> parameters, just like the marker fill color.</p>
<code>useNegPat=u</code>	<p>If <code>u=1</code>, negative fills use the mode specified by the <code>hBarNegFill</code> keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.</p>
<code>useNegRGB=u</code>	<p>If <code>u=1</code>, negative fills use the color specified by the <code>negRGB</code> keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.</p>
<code>usePlusRGB=u</code>	<p>If <code>u=1</code>, positive fills use the color specified by the <code>plusRGB</code> keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.</p>
<code>zColor={zWave,zMin,zMax,ctName [,reverseMode [,ciWave]]}</code> or 0	<p>Dynamically sets color based on the values in <code>zWave</code> and color table specified by <code>ctName</code>. Use * or a missing parameter for <code>zMin</code> and <code>zMax</code> to autoscale. See color index mode, below, for usage of <code>ciWave</code>.</p> <p><code>zWave</code> may be a subrange expression such as <code>myzWave[2,9]</code> when <code>zWave</code> has more points than the trace, in which case <code>myzWave[2]</code> provides the Z value for the first point of the trace, and autoscaled <code>zMin</code> or <code>zMax</code> is determined over only the <code>zWave</code> subrange.</p> <p>If a value in the <code>zWave</code> is NaN then a gap or missing marker will be observed. If a value is out of range it will be replaced with the nearest valid value. See also the zColorMax and zColorMin parameters.</p> <p><code>ctName</code> can be any color table name returned by the CTabList function, such as Grays or Rainbow (for color table mode), or it can be <code>cindexRGB</code> for color index mode, or <code>directRGB</code> for direct color mode.</p> <p>For color table mode, set the <code>reverseMode</code> parameter to 1 to reverse the color table; zero sets the color table to unreversed. A <code>reverseMode</code> value of -1 (or if <code>reverseMode</code> is missing) leaves the color table reverse state unchanged. Also see Color Table Details on page II-331.</p> <p>The <code>zMin</code> and <code>zMax</code> parameters are not used and should be set to *. Set <code>ctName</code> to <code>cindexRGB</code> and <code>reverseMode</code> to 0.</p> <p>Specify a 3 column wave of RGB values for <code>ciWave</code> (not for <code>zWave</code>). The <code>zWave</code> values select the color from the row of <code>ciWave</code> whose X scaling is closest to the <code>zWave</code> value.</p> <p>Example color table <code>zColor</code> command:</p> <pre>zColor(data)={myzWave[2,9],*,*,Rainbow,1}</pre> <p>You can directly specify the color of each point in a trace by using <code>directRGB</code> for <code>ctName</code>. In this case, <code>zWave</code> is a 3 column wave of RGB values (column 0 is red, 1 is green, and 2 is blue) corresponding to each point in the trace. If <code>zWave</code> is 8-bit unsigned integer, then color values range from 0 to 255; for other numeric types color values range from 0 to 65535. The <code>zMin</code> and <code>zMax</code> parameters are not used and should be set to *. Also see the ColorTab2Wave operation (which generates such a wave) and Indexed Color Details on page II-333.</p> <p>Example <code>directRGB</code> <code>zColor</code> command:</p>

`zColor(data)={zWaveRGB,*,*,directRGB}`

Color index mode uses both a *zWave* and a three-column RGB color index wave. See **Color Index Wave** on page II-308.

The *zMin* and *zMax* parameters are not used and should be set to *, set *ctName* to *cindexRGB*. Specify a value for *reverseMode*, 0 for normal, 1 for reversed color indexing. Specify a 3 column wave of RGB values for *ciWave* (not for *zWave*). Normally, the *zWave* values select the color from the row of *ciWave* whose X scaling is closest to the *zWave* value. *ReverseMode*=1 reverses the colors.

Example *cindexRGB* *zColor* command:

`zColor(data)={myZWave,*,*,cindexRGB,0,M_colors}`

(*M_colors* is generated by the **ColorTab2Wave**.)

zColor = 0 turns the *zColor* modes off.

zColorMax=(*red, green, blue*)

Sets the color of the trace for *zColor*=*{zWave, ...}* values greater than the *zColor*'s *zMax*. Also turns on *zColorMax* mode.

The *red, green, and blue* color values are in the range of 0 to 65535.

zColorMax=1, 0, or NaN

Turns *zColorMax* mode off, on, or transparent. These modes affect the color of *zColor*=*{zWave, ...}* values greater than the *zColor*'s *zMax*.

1: Turns on *zColorMax* mode. The color of the affected trace pixels is black or the last color set by *zColorMax*=(*red, green, blue*).

0: Turns off *zColorMax* mode (default). The color of the affected trace pixels is the last color in the *zColor*'s *ctname* color table.

NaN: Transparent *zColorMax* mode. Affected trace pixels are not drawn.

zColorMin=(*red, green, blue*)

Sets the color of the trace for *zColor*=*{zWave, ...}* values less than the *zColor*'s *zMin*. Also turns *zColorMin* mode on.

The *red, green, and blue* color values are in the range of 0 to 65535.

zColorMin=1, 0, or NaN

Turns *zColorMin* mode off, on, or transparent. These modes affect the color of *zColor*=*{zWave, ...}* values less than the *zColor*'s *zMin*.

1: Turns on *zColorMin* mode. The color of the affected image pixels is black or the last color set by *zColorMin*=(*red, green, blue*).

0: Turns off *zColorMin* mode (default). The color of the affected trace pixels is the first color in the *zColor*'s *ctname* color table.

NaN: Transparent *zColorMin* mode. Affected trace pixels are not drawn.

zmrkNum=*{zWave}* or 0

Dynamically sets the marker number for each point to the corresponding value in *zWave*. The values in *zWave* are the marker numbers (as used with the marker keyword). If a value in the *zWave* is NaN then no marker will be drawn at the corresponding point. If a value is out of range it will be replaced with the nearest valid value.

textMarker=0 turns this mode off.

zmrkSize=*{zWave,zMin,zMax,mrkmin,mrkmax}* or 0

Dynamically sets marker size based on values in *zWave*. Use * or a missing parameter for *zMin* and *zMax* to autoscale. *mrkmin* and *mrkmax* can be fractional. If a value in the *zWave* is NaN then a gap or missing mark will be observed. The marker size is clipped to 20 on the high end and 1 on the low end. If a value is out of range it will be replaced with the nearest valid value.

Warning: The LaserWriter printer driver will not print certain marker types if they are "too small" relative to their line thickness. For example, the circle or square markers will disappear if they fall below about 2 in size with a thickness of 0.5. This effect is not observed if exported using Igor PostScript.

zmrkSize = 0 turns this mode off.

ModifyGraph (traces)

Flags

<code>/W=winName</code>	Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the Command Line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
<code>/Z</code>	Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Details

Live Mode (`live=1`) improves graph update performance when one or more of the waves displayed in the graph is frequently modified, for example, if the waves are being acquired from a data acquisition system. Live Mode traces do not autoscale the axes.

Waves supplied with `zmrkSize`, `zmrkNum`, and `zColor` may use **Subrange Display Syntax** on page II-267.

Quick drag mode (`quickdrag=1`) is a special purpose mode for creating cross hair cursors using a package of Igor procedures. (See the Cross Hair Demo example experiment.) Normally you would have to click and hold on a trace for one second before entering drag mode. When `quickdrag` is in effect, there is no delay. If a trace is in `quickdrag` mode it should also be set to live mode. With this combination you can click a trace and immediately drag it to a new XY offset. In addition to quick drag mode, the cross hair package relies on Igor to store information about the drag in a string variable if certain conditions are in effect. The string variable name (that you have to create) is `S_TraceOffsetInfo`, which must reside in a data folder that has the same name as the graph (not title!) which in turn must reside in `root:WinGlobals:`. If these conditions are met, then after a trace is dragged, information will be stored in the string using the following key-value format: `GRAPH:<name of graph>;XOFFSET:<x offset value>;YOFFSET:<y offset value>;TNAME:<trace name>;`

Examples

Following is a simple example of arrow markers.

```
Make/N=10 wavel= x; Display wavel
Make/N=(10,2) awave
awave[][0]= p*5 // length
awave[][1]= pi*p/9 // angle
ModifyGraph mode=3,arrowMarker(wavel)={awave,1,10,0.3,0}
// Now add an optional column to control headLen
Redimension/N=(-1,3) awave
awave[][2]= 7+p // will be head length
// Note: nothing changes until the following is executed
SetDimLabel 1,2,headLen,awave
```

Create meteorological wind barb symbols.

```
Make/O/N=50 jack= floor(x/10),jackx= mod(x,10)
Display jack vs jackx
Make/O/N=(50,3) jackbarb
jackbarb[][0]= 40 // length of stem
jackbarb[][1]= 45*pi/180 // angle (45deg)
jackbarb[][2]= p // wind speed code
SetDimLabel 1,2,windBarb,jackbarb
ModifyGraph mode=3,arrowMarker(jack)={jackbarb,1,10,0.5,0}
ModifyGraph margin(top)=62,margin(right)=84
```

Inline arrows and barb sharpness.

```
Make/O/N=20 wavex=cos(x/3),wavey=sin(x)
Display wavey vs wavex
ModifyGraph mode=3,arrowMarker={_inline_,1,20,.5,0,barbSharp= 0.2}
```

Use direct color mode to individually color each point in a trace:

```
Make jack=sin(x/8)
Make/N=(128,3)/B/U jackrgb
Display jack
ModifyGraph mode=3,marker=19
jackrgb= enoise(128)+128
ModifyGraph zColor(jack)={jackrgb,*,*,directRGB}
```

Use masking.

```
Make/N=100 jack= (p&1) ? sin(x/8) : cos(x/8)
Display jack
```

```
Make/N=100 mjack= (p&1) ? 0 : NaN          // just to show NaN can be used
ModifyGraph mask(jack)={mjack,0,NaN}
// now switch which points are shown
mjack= (p&1) ? NaN : 0
```

ModifyGraph (axes)

ModifyGraph [/W=*winName*/Z] **key** [(*axisName*)] = *value*
 [, **key** [(*axisName*)] = *value*]...

This section of ModifyGraph relates to modifying the appearance of axes in a graph.

Parameters

Each *key* parameter may take an optional *axisName* enclosed in parentheses.

axisName is “left”, “right”, “top”, “bottom” or the name of a free axis such as “vertCrossing”. For instance, “ModifyGraph axThick(left)=0.5” sets the axis thickness for only the left axis.

If “(*axisName*)” is omitted, all axes in the graph are affected. For instance, “ModifyGraph standoff=0” disables axis standoff for all axes in the graph.

The parameter descriptions below omit the optional “(*axisName*)”.

axisClip= <i>c</i>	Specifies one of three clipping modes for traces. <i>c</i> =0: Clips traces to a plot rectangle as defined by the pair of axes used by a given trace (default). <i>c</i> =1: Plots traces on an axis with a restricted range (as set by axisEnab) to extend to the full range of the normal plot rectangle. <i>c</i> =2: Traces extend outside the normal plot rectangle to the full extent of the graph area.
axisEnab={ <i>lowFrac</i> , <i>highFrac</i> }	Restricts the length of an axis to a subrange of normal. The axis is drawn from <i>lowFrac</i> to <i>highFrac</i> of graph area height (vertical axis) or width (horizontal axis). For instance, {0.1,0.75} specifies that the axis is drawn from 10% to 75% of the graph area height/width, instead of the normal 0% to 100%. AxisEnab is discussed in Creating Split Axes on page II-277 and Creating Stacked Plots on page II-272.
axisOnTop= <i>t</i>	Specifies drawing level of axis and associated grid lines. <i>t</i> =0: Draws axis before traces and images (default). <i>t</i> =1: Draws the axis after all traces and images.
axOffset= <i>a</i>	Specifies the distance from default axis position to actual axis position in units of the width of a zero character (0) in a tick mark label. Unlike margin, axOffset adjusts to changes in the size of the graph.
axThick= <i>t</i>	Specifies the axis thickness in points.
barGap= <i>fraction</i>	Sets the fraction of the width available for bars to be used as gap between bars. barGap sets the gap between bars within a single category while catGap sets the gap between categories.
btLen= <i>p</i>	Sets the length of major (“big”) tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional.
btThick= <i>p</i>	Sets the thickness of major (“big”) tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default thickness. <i>p</i> may be fractional.
catGap= <i>fraction</i>	The value for catGap is the fraction of the category width to be used as gap. The gap is divided equally between the start and end of the category width. A value of 0.2 would use 20% of the available space for the gap and leave 80% of the available space for the bars. catGap sets the gap between categories while barGap sets the gap between bars within a single category.
dateFormat={ <i>languageName</i> , <i>yearFormat</i> , <i>monthFormat</i> , <i>dayOfMonthFormat</i> , <i>dayOfWeekFormat</i> , <i>layoutStr</i> , <i>commonFormat</i> }	Sets the custom date format used in the active graph.

Note: Use a custom date format only if you turn it on via a ModifyGraph dateInfo command. The last parameter to the ModifyGraph dateInfo command must be -1 to turn on the custom date format.

Parameters are the same as for the LoadWave/R flag except for the last one.

commonFormat selects the common date format to use in the Modify Graph dialog. The legal values correspond to the choices in the Common Format pop-up menu of the Modify Graph dialog. They are:

Value	Date Format	Value	Date Format
1	mm/dd/yy	16	mm/yy
2	mm-dd-yy	17	mm.yy
3	mm.dd.yy	18	Abbreviated month and year
4	mmddyy	19	Full month and year
6	dd/mm/yy	21	mm/dd
7	dd-mm-yy	22	dd.mm
8	dd.mm.yy	23	Abbreviated month and day
9	ddmmyy	24	Full month and day
11	yy/mm/dd	26	Abbreviated date without day of week
12	yy-mm-dd	27	Abbreviated date with day of week
13	yy.mm.dd	28	Full date without day of week
14	yymmdd	29	Full date with day of week

If the *commonFormat* parameter is negative, then it will select the Use Custom Format radio button in the Modify Graph dialog rather than Use Common Format and will then use the absolute value of *commonFormat* to determine which item to select in the Common Format pop-up menu.

dateInfo={*sd,tm,dt*} Controls formatting of date/time axes.

sd=0: Show date in the date&time format.

sd=1: Suppress date.

tm=0: 12 hour (AM/PM) time.

tm=1: 24 hour (military) time.

tm=2: Elapsed time.

dt=-1: Custom date as specified via the dateFormat keyword.

dt=0: Short dates (2/22/90).

dt=1: Long dates (Thursday, February 22, 1990).

dt=2: Abbreviated dates (Thurs, Feb 22, 1990).

font="fontName" Sets the axis label font, e.g., font(left)="Helvetica".

freePos(freeAxName)=*p*

Sets the position of the *free* axis relative to the edge of the plot area to which the axis is anchored. *p* is in points. i.e., if the axis was made via /R=*axName* then the axis is placed *p* points from the right edge of the plot area. Positive is away from the central plot area. *freeAxName* may not be any of the standard axes: "left", "bottom", "right" or "top".

freePos(freeAxName)={*crossAxVal,crossAxName*}

Positions the *free* axis so it will cross the perpendicular axis *crossAxName* where it has a value of *crossAxVal*. *freeAxName* may not be any of the standard axis names "left", "bottom", "right", or "top", though *crossAxName* may.

You can position a free axis as a fraction of the distance across the plot area by using **kwFraction** for *crossAxName*. *crossAxVal* must then be between 0 and 1; any values outside this range are clipped to valid values.

fsize=*s*

Autosizes (*s*=0) tick mark labels and axis labels.

If *s* is between 3 and 99 then the labels are fixed at *s* points.

<code>fstyle=f</code>	<p><i>f</i> is a binary coded number with each bit controlling one aspect of the font style for the axis and tick mark labels as follows:</p> <ul style="list-style-type: none"> bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>). bit 5: Condensed (<i>Macintosh only</i>). bit 6: Extended (<i>Macintosh only</i>). <p>See Setting Bit Parameters on page IV-11 for details about bit settings.</p>
<code>ftLen=p</code>	Sets the length of 5th (or emphasized minor) tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional.
<code>ftThick=p</code>	Sets the thickness of 5th (or emphasized minor) tick marks to <i>p</i> points (fractional). If <i>p</i> is zero, it uses the default thickness.
<code>grid=g</code>	<ul style="list-style-type: none"> <i>g</i>=0: Grid off. <i>g</i>=1: Grid on. <i>g</i>=2: Grid on major ticks only.
<code>gridEnab={lowFrac,highFrac}</code>	Restricts the length of axis grid lines to a subrange of normal. The grid is drawn from <i>lowFrac</i> to <i>highFrac</i> of graph area height (if axis is horizontal) or width (if axis is vertical).
<code>gridHair=h</code>	Sets the grid hairline thickness (<i>h</i> =0 to 3; 0 for thicker lines, 3 for thinner; default is 2). If <i>h</i> =0, the thickness of grid lines on major tick marks is the same as the axis thickness, half for a minor tick and one tenth for a subminor tick (log axis only). As <i>h</i> increases these thicknesses decrease by a factor of 2 ^{<i>h</i>} . If you want to see the effect of different values of <i>gridHair</i> , you will need to print a sample graph because you generally can't see the effect of thin lines on the screen. Also see the example experiment "Examples:Testing & Misc:Graph Grid Demo".
<code>gridStyle=g</code>	<p>Sets the grid style to various combinations of solid and dashed lines. In the following discussion, major, minor and subminor refer to grid lines the corresponding tick marks. Subminor ticks are used only on log axes when there is a small range and sufficient room (they correspond to hundredths of a decade). The different grid styles are solid, dotted, dashed, and blank. The possible grids are as follows:</p> <ul style="list-style-type: none"> <i>g</i>=0: Same as mode 1 if graph background is white else uses mode 5. <i>g</i>=1: Major dotted, minor and subminor dashed. <i>g</i>=2: All dotted. <i>g</i>=3: Major solid, minor dotted, subminor blank. <i>g</i>=4: Major and minor solid, subminor dotted. <i>g</i>=5: All solid. <p>Also see the example experiment "Examples:Testing & Misc:Graph Grid Demo".</p>
<code>highTrip=h</code>	If the extrema of an axis are between its <i>lowTrip</i> and its <i>highTrip</i> then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.
<code>lblLatPos=p</code>	Sets a lateral offset for the axis label. This is an offset parallel to the corresponding axis. <i>p</i> is in points. Positive is down for vertical axes and to the right for horizontal axes.
<code>lblMargin=l</code>	Specifies the distance from the edge of graph to a label in points.
<code>lblPos=p</code>	Sets the distance from an axis to the corresponding axis label in points. If <i>p</i> =0, it automatically picks an appropriate distance.
<code>lblPosMode= m</code>	<p>This setting is used only if the given graph edge has at least one free axis. Otherwise, the <i>lblMargin</i> setting is used to position the axis label.</p> <p>Affects the meaning and usage of <i>lblPos</i>, <i>lblLatPos</i>, and <i>lblMargin</i> parameters. Mainly for use when you have multiple axes on a side and you need axis labels to be properly positioned even as you make graph windows dramatically larger or smaller.</p> <ul style="list-style-type: none"> <i>m</i>=0: Default compatibility mode (Margin or Axis absolute depending on presence of free axis).

	<p><i>m</i>=1: Margin absolute.</p> <p><i>m</i>=2: Margin scaled.</p> <p><i>m</i>=3: Axis absolute.</p> <p><i>m</i>=4: Axis scaled.</p> <p>The absolute modes are measured in points whereas scaled modes have similar values but automatically expand or contract as the axis font height changes. Mode 0 is the default and results in no change relative to previous versions of Igor Pro that used <code>lblMargin</code> unless a given side used a free axis in which case it used <code>lblPos</code> in absolute mode. The margin modes measure relative to the position of the axis. When using stacked axes, use either margin modes. With multiple nonstacked axes, use Axis scaled if the graph edge is not using a fixed margin or use axis absolute if it is.</p>
<code>lblRot=<i>r</i></code>	Rotates the axis label by <i>r</i> degrees (truncated to 0, 90, 180, or 270). Rotation is counterclockwise and starts from the label's normal orientation.
<code>linTkLabel=<i>tl</i></code>	<i>tl</i> =1 attaches the data units with any exponent or prefix to each tick label on a normal axis. <i>tl</i> =0 removes them.
<code>log=<i>l</i></code>	<p><i>l</i>=0: Normal axis.</p> <p><i>l</i>=1: Log base 10.</p> <p><i>l</i>=2: Log base 2.</p>
<code>logHTrip=<i>h</i></code>	Same as <code>highTrip</code> but for log axes.
<code>logLabel=<i>l</i></code>	Sets the maximum number of decades in a log axis before minor tick labels are suppressed.
<code>logLTrip=<i>l</i></code>	Same as <code>lowTrip</code> but for log axes.
<code>loglinear=<i>l</i></code>	Switches to a linear tick method (<i>l</i> =1) on a log axis if the number of decades of ranges is less than 2. It switches to a linear tick exponent method if the number of decades is greater than five.
<code>logTicks=<i>t</i></code>	Sets the maximum number of decades in log axis before minor ticks are suppressed.
<code>lowTrip=<i>l</i></code>	If the extrema of an axis are between its <code>lowTrip</code> and its <code>highTrip</code> then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.
<code>manminor={<i>number</i>, <i>emphasizeEvery</i>}</code>	<p>Specifies how to draw minor ticks in manual tick mode. There will be <i>number</i> ticks between each major (labeled) tick. You will usually want to set this to 4 to make 5 divisions, or 9 to make 10 divisions. A medium-sized tick (an emphasized minor tick) will be drawn every <i>emphasizeEvery</i> minor tick.</p>
<code>manTick={<i>cantick</i>, <i>tickinc</i>, <i>exp</i>, <i>digitsrt</i> [, <i>timeUnit</i>]}</code>	<p>Turns on manual tick mode. The tick from which all other ticks are calculated is the cononic tick (<i>cantick</i>). The numerical spacing between ticks is set by <i>tickinc</i>. <i>cantick</i> and <i>tickinc</i> are multiplied by <i>10exp</i>. The number of digits to the right of the decimal point displayed in the tick labels is set by <i>digitsrt</i>.</p> <p>The optional parameter <i>timeUnit</i> is used with Date/Time axes to specify the units of <i>tickinc</i>. In this case, <i>tickinc</i> must be an integer. The value of <i>timeUnit</i> is one of the following keywords:</p> <p>second, minute, hour, day, week, month, year</p> <p>On a date/time axis, the <i>exp</i> and <i>digitsrt</i> keywords are ignored, but must be present. You can set them to zero.</p>
<code>manTick=0</code>	Turns off manual tick mode.
<code>margin=<i>m</i></code>	<p>Sets a fixed margin from the edge of the window to the axis in points. Used principally to make axes of multiple graphs on a page line up when "stacked". You can use the left, right, bottom, and top axis names (even if an axis with that name doesn't exist) to adjust the graph plot area. See Types of Axes on page II-221.</p> <p><i>m</i>=0: Sets "automatic" margin size (dependent on the length and height of tick marks and labels).</p> <p><i>m</i>=-1: Sets the margin to "none", or 0. The axis is drawn at the graph window's edge.</p>
<code>minor=<i>m</i></code>	Disables (<i>m</i> =0) or enables (<i>m</i> =1) minor ticks.
<code>mirror=<i>m</i></code>	<i>m</i> =1: Right axis mirroring left or top mirroring bottom.

	<i>m</i> =2: Mirror axis without tick marks.
	<i>m</i> =3: Mirror axis with tick marks and tick labels.
	<i>m</i> =0: No mirroring.
noLabel= <i>n</i>	<i>n</i> =0: Normal labels.
	<i>n</i> =1: Suppresses tick mark labels.
	<i>n</i> =2: Suppresses tick mark labels and axis labels.
notation= <i>n</i>	Uses engineering (<i>n</i> =0) or scientific (<i>n</i> =1) notation for tick mark labels.
	Affects tick mark labels displayed exponentially. See highTrip and lowTrip. Does not affect log axes.
nticks= <i>n</i>	Specifies the approximate number of ticks marks (<i>n</i>) on axis.
prescaleExp= <i>exp</i>	Multiplies axis range by 10^{exp} for tick labeling and <i>exp</i> is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. (This affects the display only, not the source data.)
sep= <i>s</i>	Specifies the minimum number of screen points (<i>s</i>) between minor ticks.
standoff= <i>s</i>	Suppresses (<i>s</i> =0) or enables (<i>s</i> =1) axis standoff.
	Axis standoff prevents waves or markers from covering the axis.
stLen= <i>p</i>	Sets the length of minor ("small") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional.
stThick= <i>p</i>	Sets the thickness of minor ("small") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default thickness. <i>p</i> may be fractional.
tick= <i>t</i>	Sets tick position.
	<i>t</i> =0: Outside axis.
	<i>t</i> =1: Crossing axis.
	<i>t</i> =2: Inside axis.
	<i>t</i> =3: None.
	In a category plot, adding 4 to the usual values for the tick keyword will place the tick marks in the center of each category rather than at the edges.
tickEnab={ <i>lowTick</i> , <i>highTick</i> }	Restricts axis ticking to a subrange of normal. Ticks are drawn and labelled only if they fall within this inclusive numerical range.
tickExp= <i>te</i>	<i>te</i> =1 forces tick labels to exponential notation when labels have units with a prefix. <i>te</i> =0 turns this off.
tickUnit= <i>tu</i>	Suppresses (<i>tu</i> =1) or turns on (<i>tu</i> =0) units labels attached to tick marks.
tickZap={[[<i>v1</i> [, <i>v2</i> [, <i>v3</i>]]]]}	Suppresses drawing of the tick mark label for values given in the list. This is useful when you have crossing axes to prevent tick mark labels from overlapping. The list may contain zero, one, two or three values. The values must be exact to suppress the label.
tkLblRot= <i>r</i>	Rotates the tick mark labels by <i>r</i> degrees (truncated to 0, 90, 180, or 270). Rotation is counterclockwise starting from the normal label orientation.
tlOffset= <i>o</i>	Offsets the tick mark labels by <i>o</i> fractional points relative to the default tick mark label position. Positive is away from the axis.
ttLen= <i>p</i>	Sets the length of subminor ("tiny") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional. Subminor ticks are used only in log axes.
ttThick= <i>p</i>	Sets the thickness of subminor ("tiny") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default thickness. <i>p</i> may be fractional.
userticks={ <i>tickPosWave</i> , <i>tickLabelWave</i> }	Draws axes with purely user-defined tick mark positions and labels. <i>tickPosWave</i> is a numeric wave containing the desired positions of the tick marks, and <i>tickLabelWave</i> is a text wave containing the labels.
	The tick mark labels can be multiline and use styled text. For more details, see Fancy Tick Mark Labels on page II-290.
	<i>tickPosWave</i> need not be monotonic. Igor will plot a tick if a value is in the range of the axis. Both linear and log axes are supported.

ModifyGraph (axes)

	Graph margins will adjust to accommodate tick labels. This will not prevent overlap between labels, which you will need fix yourself.
zapLZ= <i>t</i>	Removes (<i>t</i> =1) leading zeros from tick mark labels. For example 0.5 becomes .5 and -0.5 becomes -.5. Default is <i>t</i> =0.
zapTZ= <i>t</i>	Removes (<i>t</i> =1) trailing zeros from tick mark labels. The the radix point will also be removed if all digits are zero. Default is <i>t</i> =0.
zero= <i>z</i>	<i>z</i> =1: Zero line at <i>x</i> =0 or <i>y</i> =0. <i>z</i> =0: No zero line.
zeroThick= <i>zt</i>	Sets the thickness of the zero line in points, from 0.0 to 5.0 points. <i>zt</i> =0.0 means the zero line thickness automatically follows the thickness of the axis; this is the default. You can use 0.1 for a thin zero line thickness.
ZisZ= <i>t</i>	<i>t</i> =1 uses the single digit 0 as the zero tick mark label (if any) regardless of the number of digits used for other labels. Default is <i>t</i> =0.

Flags

/W= <i>winName</i>	Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Z	Does not generate an error if the named axis does not exist in a style macro.

Details

With the `prescaleExp` parameter, you can force tick and axis label scaling to values different from the defaults. For example, if you have data whose X scaling ranges from 9pA to 120pA and you display this on a log axis, the tick marks will be labelled 10pA and 100pA. But if you really want the tick marks labeled 10 and 100 with pA in the axis label, you can set the `prescaleExp` to 12. To see this, execute the following commands:

```
Make/O jack=x
Display jack
SetScale x,9e-12,120e-12,"A",jack
ModifyGraph log(bottom)=1
```

then execute:

```
ModifyGraph prescaleExp(bottom)=12
```

The `tickExp` parameter applies to units that do not traditionally use SI prefix characters. For example, one usually speaks of 10^{-3} Torr and not mTorr. To see how this feature works, execute the following example commands:

```
Make/O jack=x
Display jack
SetScale x,1E-7,1E-5,"Torr",jack
ModifyGraph log(bottom)=1
```

then execute:

```
ModifyGraph tickExp(bottom)=1
```

at this point, the tick mark labels have Torr in them. If you want to eliminate the units from the tick marks, execute:

```
ModifyGraph tickUnit(bottom)=1
```

and if you now want Torr in the label string, use the `\U` escape in the label string:

```
Label bottom "\\U"
```

To see the effect of `linTkLabel`, execute these commands:

```
Make/O jack=x
Display jack
SetScale x,1E-7,1E-5,"Torr",jack
```

then execute:

```
ModifyGraph linTkLabel(bottom)=1
```

and then try:

```
ModifyGraph tickExp(bottom)=1
```

and finally:

```
ModifyGraph tickUnit(bottom)=1
```

ModifyGraph (colors)

ModifyGraph [/W=*winName*/Z] **key** [(*axisName*)] = (*r*,*g*,*b*)
 [, **key** [(*axisName*)] = (*r*,*g*,*b*)]...

This section of ModifyGraph relates to modifying the use of colors in a graph.

Parameters

Most (but not all) of the *key* parameters may take an optional *axisName* enclosed in parentheses. *axisName* is "left", "right", "top", "bottom" or the name of a free axis such as "vertCrossing".

Where the parameter descriptions indicate an "(*axisName*)", it may be omitted to change all axes in the graph.

r, *g*, and *b* are each an integer from 0 to 65535 where (0, 0, 0) is black and (65535, 65535, 65535) is white.

Parameter Specification	Object Colored
alblRGB(<i>axisName</i>)=(<i>r</i> , <i>g</i> , <i>b</i>)	Axis labels
axRGB(<i>axisName</i>)=(<i>r</i> , <i>g</i> , <i>b</i>)	Axis
cbRGB=(<i>r</i> , <i>g</i> , <i>b</i>)	Control bar background
gbRGB=(<i>r</i> , <i>g</i> , <i>b</i>)	Graph background
gridRGB(<i>axisName</i>)=(<i>r</i> , <i>g</i> , <i>b</i>)	Axis grid lines
tickRGB(<i>axisName</i>)=(<i>r</i> , <i>g</i> , <i>b</i>)	Axis Tick marks
tlblRGB(<i>axisName</i>)=(<i>r</i> , <i>g</i> , <i>b</i>)	Axis Tick labels
wbRGB=(<i>r</i> , <i>g</i> , <i>b</i>)	Window background

Flags

/W=*winName* Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
 When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z Does not generate an error if the named axis does not exist in a style macro.

Details

On Windows, use maximum white to set the control bar background color to track the 3D Objects color in the Appearance Tab of the Display Properties control panel:

```
ModifyGraph cbRGB=(65535,65535,65535)
```

See Also

See **Instance Notation** on page IV-16.

ModifyImage

ModifyImage [/W=*winName*] *imageInstance* **keyword** = *value*
 [, **keyword** = *value*]...

The ModifyImage operation changes properties of the given image in the top graph (or the specified graph if /W is used). *imageInstance* is the name of the image to be altered. This name is usually simply the name of the matrix wave containing the image data. If the same matrix wave is displayed more than once, you must append #0, #1 etc. to the name to distinguish which is which.

imageInstance can also take the form of a null name with an instance number to affect the instance image. That is,

```
ModifyImage ''#1
```

modifies the appearance of the second image that was appended to the top graph, no matter what the image names are. Note: two single quotes are used, not a double quote.

Parameters

Here are the keyword-value pairs. These apply to false color images in which the data in the matrix is used as an index into a color table. They do not apply to direct color images in which the data in the matrix specifies the color directly.

cindex=*matrixWave* Sets the Z value mapping mode such that image colors are determined by doing a lookup in the specified matrix wave.

matrixWave is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than 3 columns. It ignores any extra columns.)

The color at $Z=z$ is determined by finding the RGB values in the row of *matrixWave* whose scaled X index is z . In other words, the red value is *matrixWave*(z)[0], the green value is *matrixWave*(z)[1] and the blue value is *matrixWave*(z)[2].

If *matrixWave* has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for $Z=0$, row 1 contains the color for $Z=1$, etc.

If you use **cindex**, you should not use **ctab** in the same command.

ctab={*zMin*, *zMax*, *ctName*, *reverse*}

Sets z mapping mode by which values in the matrix are mapped linearly into the color table specified by *ctName*. The color table name can be missing if you want to leave it as is. *zMin* and *zMax* set the range of z values to map. Omit *zMin* or *zMax* to leave as is or use * to autoscale. *ctName* can be any color table name returned by the **CTabList** function, such as Grays or Rainbow. Also see **Color Tables** on page II-327. Set parameter *reverse* to 1 to reverse the color table; zero or missing does not reverse the color table.

ctabAutoscale=*autoBits*

Sets the range of data used for autoscaling **ctab** * values.

Bit 0: Autoscales only the XY subset being displayed.

Bit 1: Autoscales only the current plane being displayed.

If neither bit is set (if *autoBits* = 0, the default), then all of the data in the image wave is used to autoscale the *d *zMin*, *zMax* values for **ctab**.

eval={*value*, *red*, *green*, *blue*}

If the red, green, and blue values are in the valid range for a color value (0 to 65535) the explicit value-color pair is added (or updated if value already exists). If the color values are out of range (-1 is suggested) then the value is removed from the list if it is present (no error if it is not).

explicit=1 or 0

Turns explicit (monochrome) mode on (1) or off (0). Meant to be used with unsigned byte data but will do the best it can for other types. If value of data is equal to one of the defined explicit values then its defined color is used otherwise the pixel will be blank. The default predefined values are:

255 black

0 white

You can add, change, or delete explicit values with the **eval** keyword.

lookup=*waveName* Specifies an optional 1D wave that can be used to modify the mapping of scaled z values into the color table specified with the **ctab** parameter. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use a NULL wave ("") to remove the option.

maxRGB=(*red*, *green*, *blue*)

Sets the color of image values greater than the **ctab** *zMax* or greater than the **cindex** of the *matrixWave* maximum X scaling value. Also turns max color mode on.

The *red*, *green*, and *blue* color values are in the range of 0 to 65535.

maxRGB=1 or 0 or NaN

Turns max color mode off, on, or transparent. These modes affect the display of image values greater than the **ctab** *zMax* or greater than the **cindex** of the *matrixWave* maximum X scaling value.

1: Turns on max color mode. The color of the affected image pixels is black or the last color set by **maxRGB**=(*red*, *green*, *blue*).

	0:	Turns off max color mode (default). The color of the affected image pixels is the last color table or color index color.
	NaN:	Transparent max color mode. The affected image pixels are not drawn.
minRGB=(red, green, blue)		Sets the color of image values less than the <i>ctab zMin</i> or less than the <i>cindex</i> of the <i>matrixWave</i> minimum X scaling value. Also turns min color mode on. The <i>red</i> , <i>green</i> , and <i>blue</i> color values are in the range of 0 to 65535.
minRGB=1 or 0 or NaN		Turns min color mode off, on, or transparent. These modes affect the display of image values less than the <i>ctab zMin</i> or less than the <i>cindex</i> of the <i>matrixWave</i> minimum X scaling value.
	1:	Turns on min color mode. The color of the affected image pixels is black or the last color set by minRGB=(red, green, blue).
	0:	Turns off min color mode (default). The color of the affected image pixels is the first color table or color index color.
	NaN:	Transparent min color mode. The affected image pixels are not drawn.
plane=p		If the image data is a volume, <i>p</i> specifies which matrix subset to show. Note: if the image data contains exactly 3 layers then the image is assumed to be RGB and <i>p</i> specifies the chunk number rather than the layer number.
Flags		
/W=winName		Directs action to a specific window or subwindow rather than the top graph window. When omitted, action will affect the active window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also

AppendImage and RemoveImage.

ModifyLayout

ModifyLayout [*flags*] **key** [(*objectName*)] =value [, **key** [(*objectName*)] =value]...

The ModifyLayout operation modifies objects in the top layout or in the layout specified by the /W flag.

Parameters

Each *key* parameter may take an optional *objectName* enclosed in parentheses. If “(*objectName*)” is omitted, all objects in the layout are affected.

Though not shown in the syntax, the optional “(*objectName*)” may be replaced with “[*objectIndex*]”, where *objectIndex* is zero or a positive integer denoting the object to be modified. “[0]” denotes the first object appended to the layout, “[1]” denotes the second object, etc. This syntax is used for style macros, in conjunction with the /Z flag.

The parameter descriptions below omit the optional “(*objectName*)”.

The “units”, “mag” and “bgRGB” keywords apply to the layout as a whole, not to a specific object and do not accept an *objectName*.

bgRGB=(r,g,b)	Specifies the background color for the layout. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
columns=c	Specifies the number of columns for a table object.
fidelity=f	<i>f</i> =0: Low fidelity. <i>f</i> =1: High fidelity.
frame=f	Specifies the type of frame enclosing the object. <i>f</i> =0: No frame. <i>f</i> =1: Single frame. <i>f</i> =2: Double frame. <i>f</i> =3: Triple frame. <i>f</i> =4: Shadow frame.
height=h	Sets the height of the object.

ModifyPanel

<code>left=<i>l</i></code>	<i>l</i> is the horizontal coordinate of the left edge of the object relative to the left edge of the paper.
<code>mag=<i>m</i></code>	Sets the layout magnification where <i>m</i> =0.25, 0.5, 1, or 2.
<code>rows=<i>r</i></code>	Specifies the number of rows for table object.
<code>top=<i>t</i></code>	<i>t</i> is the vertical coordinate of the top edge of the object relative to the top edge of the paper.
<code>trans=<i>t</i></code>	<i>t</i> =0: Opaque (default). <i>t</i> =1: Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque, and Igor cannot make an opaque PICT transparent.
<code>units=<i>u</i></code>	Sets dimension units in the layout info panel and in the Modify Objects dialog. <i>u</i> =0: Points. <i>u</i> =1: Inches. <i>u</i> =2: Centimeters.
<code>width=<i>w</i></code>	Sets the object width.
Flags	
<code>/I</code>	Dimensions in inches.
<code>/M</code>	Dimensions in centimeters.
<code>/W=<i>winName</i></code>	<i>winName</i> is the name of the page layout window to be modified. If <code>/W</code> is omitted or if <i>winName</i> is \$" ", the top page layout is modified.
<code>/Z</code>	Does not generate an error if the indexed or named object does not exist in a style macro.

The `/I` and `/M` flags affect the units of the parameters for the left, top, width and height keywords only. If neither `/I` nor `/M` is present then the parameters for the left, top, width and height keywords are points.

Details

Note that the units keyword affects only the units used in the layout info panel and in the Modify Objects dialog. It has nothing to do with the units used for the left, top, width and height keywords. Those units are points unless the `/I` or `/M` flags is present.

See Also

`NewLayout`, `AppendLayoutObject` and `RemoveLayoutObjects`.

ModifyPanel

ModifyPanel [`/W=winName`] **keyword** = **value** [, **keyword** = **value** ...]

The `ModifyPanel` operation modifies properties of the top or named control panel window or subwindow.

Parameters

keyword is one of the following:

<code>cbRGB=(<i>r,g,b</i>)</code>	Specifies the background color of the entire control panel or the graph's control bar area. <i>r</i> , <i>g</i> , and <i>b</i> are values from 0 to 65535.
<code>fixedSize=<i>f</i></code>	<i>f</i> =0: Panel can be resized (default). <i>f</i> =1: Panel cannot be resized by adjusting the size box or frame (nor maximized on Windows), but the window can be minimized (on Windows) and the <code>MoveWindow</code> operation can still change the size.
<code>frameInset=<i>i</i></code>	Specifies the number of pixels by which to inset the frame of the panel subwindow. Mostly useful for overlaying panels in graphs to give a fake 3D frame a better appearance.
<code>frameStyle=<i>f</i></code>	Specifies the frame style for a panel subwindow. <code>frameStyle</code> values are: 0: None. 1: Single. 2: Indented. 3: Raised. 4: Text well.

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the panel itself is a light shade of gray.

noEdit= *e* Sets the editability of the panel.

e=0: Editable (default).

e=1: Not editable. For a panel window, the Panel menu item is not present and the ShowTools command is ignored. For a panel subwindow, it can not be activated by clicking.

Flags

/W= *winName* Modifies the control panel in the named graph or control panel window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

On Windows, set *r*, *g*, and *b* = 65535 (maximum white) to set the background color of the control panel to track the 3D Objects color in the Appearance Tab of the Display Properties control panel.

See Also

Controls in Graphs on page III-372.

ModifyTable

ModifyTable [/W=*winName*/Z] **key** [(*columnSpec*)] =*value* [, **key** [(*columnSpec*)] =*value*]...

The ModifyTable operation modifies the appearance the top or named table window or subwindow.

Parameters

Many of the parameter keywords take an optional *columnSpec* enclosed in parentheses. Usually *columnSpec* is simply the name of a wave displayed in the table. All table columns are affected when you omit (*columnSpec*).

More precisely, column specifications are wave names for waves in the current data folder or data folder paths leading to waves in any data folder optionally followed by the suffixes .i, .l, .d, .id or .ld to specify dimension indices, dimension labels, data values, dimension indices and data values, or dimension labels and data values of the wave. For example, **ModifyTable font(myWave.i) = "Helvetica"**. If the wave is complex, the column specification may be followed by .real or .imag suffixes.

One additional *columnSpec* is Point, which refers to the first column containing the dimension index numbers. If multidimensional waves are displayed in the table, this column may have the title "Row", "Column", "Layer", "Chunk" or "Element", but the *columnSpec* for this column is always Point. See **Column Names** on page II-180 for details.

Though not shown in the syntax, the optional (*columnSpec*) may be replaced with [*columnIndex*], where *columnIndex* is zero or a positive integer denoting the column to be modified. [0] denotes the Point column, [1] denotes the first column appended to the table, [2] denotes the second appended column, etc. This syntax is used for style macros, in conjunction with the /Z flag.

As of Igor Pro 6 you can use a range of column numbers instead of just a single column number, for example [0, 3].

The parameter descriptions below omit the optional (*columnSpec*).

alignment=*a* *a*=0: Left aligned.

a=1: Center aligned.

a=2: Right aligned.

autosize={*mode, options, perColumnMaxSeconds, totalMaxSeconds*}

Autosizes the specified column or columns.

mode=0: Sets width of each data column from a given multidimensional wave individually.

mode=1: Sets width of all data columns from a given multidimensional wave the same.

options is a bitwise parameter. Usually 0 is the best choice.

bit 0: Ignores column names.

bit 1: Ignores horizontal indices.

bit 2: Ignores data cells.

	<p>All other bits are reserved and must be set to zero.</p> <p>See Setting Bit Parameters on page IV-11 for details about bit settings.</p> <p><i>padding</i> specifies extra padding for each column in points. Use -1 to get the default amount of padding (16 points).</p> <p><i>perColumnMaxSeconds</i> specifies the maximum amount of time to spend autosizing a single column. Use 0 to get the default amount of time (one second).</p> <p><i>totalmaxSeconds</i> specifies the maximum amount of time for autosizing the entire table. Use 0 to get the default amount of time (ten seconds).</p>
<code>digits=d</code>	<p>Specifies the number of digits after decimal point or, for hexadecimal and octal columns, the number of total digits.</p>
<code>elements=(row, col, layer, chunk)</code>	<p>Selects the view of a multidimensional wave in the table. The values given to <i>row</i>, <i>col</i>, <i>layer</i>, and <i>chunk</i> specify how to change the view.</p> <ul style="list-style-type: none"> -1: No change from current view. -2: Display this dimension vertically. -3: Display this dimension horizontally. ≥0: For waves with 3 or 4 dimensions, display this element of the other dimensions. <p>See ModifyTable Elements Command on page II-203 for a detailed discussion of this keyword.</p>
<code>entryMode=m</code>	<p>Queries or sets the table's entry line mode.</p> <ul style="list-style-type: none"> <i>m</i>=0: Just queries. <i>m</i>=1: Accepts any entry that was started if possible. <i>m</i>=2: Cancels any entry that was started if possible. <p>If <i>m</i> is 0 then the entry line state is not changed but is returned via <i>V_flag</i> as follows:</p> <ul style="list-style-type: none"> 0: No entry is in progress. -1: An entry is in progress and is valid. Other: An entry is in progress and is invalid. <p>If <i>m</i> is 1 then the entry is accepted if it is valid and its state is returned via <i>V_flag</i> as follows:</p> <ul style="list-style-type: none"> 0: No entry is in progress. -1: The entry was accepted. Other: The entry is invalid and was not accepted. <p>If <i>m</i> is 2 then the entry is cancelled if possible and its state is returned via <i>V_flag</i> as follows:</p> <ul style="list-style-type: none"> 0: No entry is in progress. -1: The entry was cancelled.
<code>font="fontName"</code>	<p>Sets font used in the table, e.g., <code>font="Helvetica"</code>.</p>
<code>format=f</code>	<p>Sets the data format for the table.</p> <ul style="list-style-type: none"> <i>f</i>=0: General. <i>f</i>=1: Integer. <i>f</i>=2: Integer with thousands (e.g., "1,234"). <i>f</i>=3: Fixed point (e.g., "1234.56"). <i>f</i>=4: Fixed point with thousands (e.g., "1,234.56"). <i>f</i>=5: Exponential (scientific only). <i>f</i>=6: Date format. <i>f</i>=7: Time format (always 24 hour time). <i>f</i>=8: Date&time format (date followed by time). <i>f</i>=9: Octal. <i>f</i>=10: Hexadecimal.

	As of Igor Pro 6, you cannot apply date or date&time formats to a wave that is not double-precision (see Date, Time, and Date&Time Units on page II-72). To avoid this error, use Redimension to change the wave to double-precision.
frameInset= <i>i</i>	Specifies the number of pixels by which to inset the frame of the table subwindow.
frameStyle= <i>f</i>	Specifies the frame style for a table subwindow. frameStyle values are: <ul style="list-style-type: none"> 0: None 1: Single 2: Double 3: Triple 4: Shadow 5: Indented 6: Raised 7: Text well <p>The last three styles are fake 3D and will look good only if the background color of the enclosing space and the table itself is a light shade of gray.</p>
horizontalIndex= <i>h</i>	Controls what is displayed in the horizontal index row when multidimensional waves are displayed. <ul style="list-style-type: none"> <i>h</i>=0: Displays dimension labels if the multidimensional wave's label column is displayed, otherwise displays numeric indices (default). <i>h</i>=1: Always displays numeric indices for multidimensional waves. <i>h</i>=2: Always displays dimension labels for multidimensional waves. <p>The horizontal index row appears below the row of column names if the table contains a multidimensional wave. Use horizontalIndex to override the default behavior in order to display labels for the horizontal dimension while displaying numeric indices for the vertical dimension or vice versa.</p> <p>horizontalIndex controls the horizontal index row only. To control what is displayed vertically, use AppendToTable to append a numeric index or dimension label column.</p>
rgb=(<i>r</i> , <i>g</i> , <i>b</i>)	Sets color of text. <i>r</i> , <i>g</i> , and <i>b</i> are red, green, and blue components of the color and range from 0 to 65,535. Default is black: (0,0,0).
selection=(<i>firstRow</i> , <i>firstCol</i> , <i>lastRow</i> , <i>lastCol</i> , <i>targetRow</i> , <i>targetCol</i>)	Sets the selected cells in the table. <p>If any of the parameters have the value -1 then the corresponding part of the selection is not changed.</p> <p>Otherwise they set the first and last selected cell and the target cell. Row and column values are 0 or greater. The Point column can not be selected.</p> <p>The proposed parameters are clipped to avoid invalid combinations, such as the last selected row being before the first selected row.</p> <p>With one exception, it does not support selecting unused cells. Therefore the proposed selection is clipped to prevent this. The exception is that, if the parameters call for selecting the first cell in the first unused column, then this is permitted.</p>
showFracSeconds= <i>s</i>	Shows (<i>s</i> =1) or hides (<i>s</i> =0; default) fractional seconds.
showParts= <i>parts</i>	Specifies what elements of the table should be visible. Other elements are hidden. <p><i>parts</i> is a bitwise parameter specifying what to show.</p> <ul style="list-style-type: none"> bit 0: Entry line and other top line controls. bit 1: Name row. bit 2: Horizontal index row. bit 3: Point column. bit 4: Horizontal scroll bar. bit 5: Vertical scroll bar. bit 6: Selection highlighting. bit 7: Insertion cells.

All other bits are reserved and must be set to zero except that you can pass -1 to indicate that you want to show all parts of the table.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Presentation tables in subwindows in graphs and page layouts do not have an entry line or scroll bars and therefore never show these items.

See **Parts of a Table** on page II-174 and **Showing and Hiding Parts of a Table** on page II-175 for further information.

sigdigits=*d*

d is the number of significant digits when the numeric format is general.

size=*s*

Font size, e.g., size=14.

style=*n*

n is a binary coded number with each bit controlling one aspect of the column's font style as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

bit 5: Condensed (*Macintosh only*).

bit 6: Extended (*Macintosh only*).

For example, bold underlined is $2^0 + 2^2 = 1 + 4 = 5$. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

title="title"

Sets the title of a column to *title*.

topLeftCell=(*row*, *column*)

Scrolls the table contents so that the cell identified by (*row*, *column*) is the top left visible data cell, or as close as possible.

If *row* is -1 then the table's vertical scrolling is not changed. If *column* is -1 then the table's horizontal scrolling is not changed.

If they are positive, *row* and *column* are zero-based numbers which are clipped to valid values before being used. *row*=0 refers to the first row of data in the table, *column*=0 refers to the first column of data.

The Point column can not be scrolled horizontally.

trailingZeros=*t*

Shows trailing zeros (*t*=1). This affects the general numeric format only.

width=*w*

Sets column width to *w* points.

You will not always get the exact number of points that you request. This is because a column must have an even number of screen pixels, so that grid lines look good. Igor will modify your requested number of points to meet this requirement.

Flags

/W= *winName*

Modifies the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z

No errors generated if the indexed or specified column does not exist in a style macro.

Examples

```
ModifyTable size(myWave)=14          // change font size of myWave column
ModifyTable width(Point)=0           // hide Point column
ModifyTable style(cmplxWave.imag)=32 // condensed= bit 5 = 2^5 = 32
```

See Also

See **Column Names** on page II-180 and **ModifyTable Elements Command** on page II-203.

ModifyWaterfall

ModifyWaterfall [*/W=winName*] **keyword** = **value** [, **keyword** = **value** ...]

The ModifyWaterfall operation modifies the properties of the waterfall plot in the top or named graph.

Parameters

keyword is one of the following:

<i>angle</i> = <i>a</i>	Angle in degrees from horizontal of the angled Y axis (<i>a</i> =10 to 90).
<i>axlen</i> = <i>len</i>	Relative length of angled Y axis. <i>len</i> is a fraction between 0.1 and 0.9.
<i>hidden</i> = <i>h</i>	<i>h</i> =0: Turns hidden lines off. <i>h</i> =1: Uses painter's algorithm. <i>h</i> =2: True hidden. <i>h</i> =3: Hides lines with bottom removed. <i>h</i> =4: Hides lines using a different color for the bottom. When specified, the top color is the normal color for lines and the bottom color is set using ModifyGraph <i>negRGB</i> =(<i>r</i> , <i>g</i> , <i>b</i>). Hidden lines are active only when the mode is lines between points.

Flags

<i>/W= winName</i>	Modifies waterfall plot in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
--------------------	--

Details

Painter's algorithm draws the traces from back to front and erases hidden lines while modes 2, 3 and 4 detect which line segments are hidden and suppresses the drawing of these segments.

See Also

The **NewWaterfall** and **ModifyGraph** operations.

ModuleName

#pragma ModuleName = *modName*

The ModuleName pragma assigns a name, which must be unique, to a procedure file so that you can use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line.

Using the ModuleName pragma involves at least two steps. First, within the procedure file assign it a name using **#pragma ModuleName=modName**, and then access objects in the named file by preceding the object name with the name of the module and the # character, such as or example: **ModName#StatFuncName** ().

The ModuleName pragma will not work with versions of Igor older than 5.0.

See Also

The **The ModuleName Pragma** on page IV-40, **Static**, **Picture**, and **#pragma**.

MoveDataFolder

MoveDataFolder *sourceDataFolderSpec*, *destDataFolderPath*

The MoveDataFolder operation removes the source data folder (and everything it contains) and places it at the specified location with the original name.

Parameters

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details

MoveDataFolder generates an error if a data folder of the same name already exists at the destination.

Examples

Move data folder `foo` into data folder `bar`:

```
MoveDataFolder foo,root:bar:
```

Move data folder `foo` into data folder `bar`:

```
MoveDataFolder foo,:bar:
```

See Also

See the **DuplicateDataFolder** operation. Chapter II-8, **Data Folders**.

MoveFile

MoveFile [*flags*][*srcFileStr*] [*as destFileOrFolderStr*]

The MoveFile operation moves or renames a file on disk. A file is renamed by “moving” it to the same folder it is already in using a different name.

Parameters

srcFileStr can be a full path to the file to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the file from *srcFileStr* and *pathName*, it displays an Open File dialog allowing you to specify the source file.

destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If /D is specified, the source file is moved inside the folder using the source file’s name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Flags

/D	Interprets <i>destFileOrFolderStr</i> as the name of (or path to) an existing folder (or directory). Without /D, <i>destFileOrFolderStr</i> is the name of (or path to) a file. If <i>destFileOrFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> .
/I [=i]	Specifies the level of interactivity with the user. /I=0: Interactive only if one or <i>srcFileStr</i> or <i>destFileOrFolderStr</i> is not specified or if the source file is missing. (Same as if /I was not specified.) /I=1: Interactive even if <i>srcFileStr</i> is specified and the source file exists. /I=2: Interactive even if <i>destFileOrFolderStr</i> is specified. /I=3: Interactive even if <i>srcFileStr</i> is specified and the source file exists. Same as /I only.
/M= <i>messageStr</i>	Specifies the prompt message in the Open File dialog. If /S is not specified, then <i>messageStr</i> will be used for both Open File and for Save File dialogs.
/O	Overwrite existing destination file, if any. Without /O, the user is asked if replacing the existing file is to be allowed.
/P= <i>pathName</i>	Specifies the folder to look in for the source file, and the folder into which the file is copied. <i>pathName</i> is the name of an existing symbolic path. Using /P means that both <i>srcFileStr</i> and <i>destFileOrFolderStr</i> must be either simple file or folder names, or paths relative to the folder specified by <i>pathName</i> .
/S= <i>saveMessageStr</i>	Specifies the prompt message in the Save File dialog.
/Z[=z]	Prevents procedure execution from aborting if it attempts to move a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

/Z=0: Same as no /Z at all.
 /Z=1: Moves a file only if it exists. /Z alone has the same effect as /Z=1.
 /Z=2: Moves a file if it exists or displays a dialog if it does not exist.

Variables

The MoveFile operation returns information in the following variables:

V_flag	Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
S_fileName	Stores the full path to where the file was moved from. If an error occurred or if the user cancelled, it is set to an empty string.
S_path	Stores the full path where the file was moved to. If an error occurred or if the user cancelled, it is set to an empty string.

Examples

Rename a file, using full paths:

```
MoveFile "HD:folder:aFile.txt" as "HD:folder:bFile.txt"
```

Rename a file, using a symbolic path:

```
MoveFile/P=myPath "aFile.txt" as "bFile.txt"
```

Move a file into a subfolder (the subfolder must exist):

```
MoveFile/D "Macintosh HD:folder:aFile.txt" as ":subfolder"
```

Move a file into an unrelated folder (the subfolder must exist):

```
MoveFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
```

Move a file from one folder to another and rename it:

```
MoveFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
```

Move user-selected file into a particular folder:

```
MoveFile/D as "C:My Documents:Selected Files Folder"
```

Move user-selected file in any folder as bFile.txt in same folder:

```
MoveFile as "bFile.txt"
```

Move user-selected file in any folder as bFile.txt in any folder:

```
MoveFile/I=2 as "bFile.txt"
```

The **Open**, **MoveFolder**, **CopyFolder**, **NewPath**, and **CreateAliasShortcut** operations. The **IndexedFile** function. **Symbolic Paths** on page II-30.

MoveFolder

MoveFolder [*flags*][*srcFolderStr*] [*as destFolderStr*]

The MoveFolder operation moves or renames a folder on disk. A folder is renamed by “moving” it into the same folder it is already in, but with a different name.

Warning: *The MoveFolder command can destroy data by overwriting another folder and its contents!*

If you overwrite an existing folder on disk, MoveFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog’s Misc category. For further details see **Misc Settings** on page III-398.

If permission is denied, the folder will not be moved and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

Parameters

srcFolderStr can be a full path to the folder to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a folder within the folder associated with *pathName*.

If the location of the source folder cannot be determined from *srcFolderStr* and *pathName*, it displays a Select Folder dialog allowing you to specify the source.

MoveFolder

If */P=pathName* is given, but *srcFolderStr* is not, then the folder associated with *pathName* is moved or renamed. *destFolderStr* specifies the final location of the folder or, if */D* is used, the parent of the final location of the folder. *destFolderStr* can be a full path to the output (destination) folder (in which case */P* is not needed), or a partial path relative to the folder associated with *pathName*.

If the location of the destination folder cannot be determined from *destFolderStr* and *pathName*, it displays a Save Folder dialog allowing you to specify the destination.

If you use a full or partial path for either file, see **Path Separators** on page III-382 for details on forming the path.

Flags

<i>/D</i>	Interprets <i>destFolderStr</i> as the name of (or path to) an existing folder (or “directory”) to move the source folder into. Without <i>/D</i> , it interprets <i>destFolderStr</i> as the name of (or path to) the moved folder. If <i>destFolderStr</i> is not a full path to a folder, it is relative to the source folder.
<i>/I [=i]</i>	Specifies the level of interactivity with the user. <i>/I=0:</i> Interactive only if one or <i>srcFolderStr</i> or <i>destFolderStr</i> is not specified or if the source folder is missing. (Same as if <i>/I</i> was not specified.) <i>/I=1:</i> Interactive even if <i>srcFolderStr</i> is specified and the source file exists. <i>/I=2:</i> Interactive even if <i>destFolderStr</i> is specified. <i>/I=3:</i> Interactive even if <i>srcFolderStr</i> is specified and the source file exists. Same as <i>/I</i> only.
<i>/M=messageStr</i>	Specifies the prompt message in the Open File dialog. If <i>/S</i> is not used, then <i>messageStr</i> will be used for both Open File and for Save File dialogs.
<i>/O</i>	Overwrite existing destination folder, if any. This deletes the existing destination folder. When <i>/O</i> is specified, the source folder can’t be moved into an existing folder without specifying the name of the moved folder in <i>destFolderStr</i> .
<i>/P=pathName</i>	Specifies the folder for relative paths in <i>srcFolderStr</i> and <i>destFolderStr</i> . <i>pathName</i> is the name of an existing symbolic path. If <i>srcFolderStr</i> is omitted, the folder associated with <i>pathName</i> is moved. If <i>destFolderStr</i> is omitted, the source folder is moved into the folder associated with <i>pathName</i> . Using <i>/P</i> means that <i>srcFolderStr</i> (if specified) and <i>destFolderStr</i> must be either simple folder names or paths relative to the folder specified by <i>pathName</i> .
<i>/S=saveMessageStr</i>	Specifies the prompt message in the Save File dialog.
<i>/Z [=z]</i>	Prevents procedure execution from aborting if it attempts to move a file that does not exist. Use <i>/Z</i> if you want to handle this case in your procedures rather than having execution abort. <i>/Z=0:</i> Same as no <i>/Z</i> at all. <i>/Z=1:</i> Moves a file only if it exists. <i>/Z</i> alone has the same effect as <i>/Z=1</i> . <i>/Z=2:</i> Moves a file if it exists or displays a dialog if it does not exist.

Variables

The MoveFolder operation returns information in the following variables:

<i>V_flag</i>	Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
<i>S_fileName</i>	Stores the full path to the folder that was moved, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.
<i>S_path</i>	Stores the full path of the moved folder, with a trailing semicolon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only */P=pathName* (omitting *srcFolderStr*) to specify the source folder to be moved.

A folder path should not end with single Path Separators. For example:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder:"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder:"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder:"
```

will do weird, unexpected things (and probably damaging things when /O is also used). Instead, use:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
```

Beware of PathInfo and other command which return paths with an ending path separator. (They can be removed with the **RemoveEnding** function.)

A folder may not be moved into one of its own subfolders.

Conversely, the command:

```
MoveFolder/O/P=myPath "afolder"
```

which attempts to overwrite the folder associated with myPath with a folder that is inside it (namely "afolder") is not allowed. Instead, use:

```
MoveFolder/O/P=myPath "::afolder"
```

On Windows, renaming or moving a folder never updates the value of any Igor Symbolic Paths that point to a moved folder:

```
// Create a folder
NewPath/O/C myPath "C:\\My Documents\\My Work"

// Move the folder
MoveFolder/P=myPath as "C:\\My Documents\\Moved"

// Display the path's value
PathInfo myPath          // (or use the Path Status dialog)
Print S_Path
· C:My Documents:My Work
```

You can use PathInfo to determine if a folder referred to by an Igor symbolic path exists and where it is on the disk. Use NewPath/O to reset the path's value.

On the Macintosh, however, renaming or moving a folder on the same volume does alter the value of symbolic path. This is because MoveFolder uses a Mac OS alias to keep track of the folder. A folder renamed or moved on the same volume retains the original "volume refnum" and "directory ID" stored in the alias mechanism, so that the alias (and hence Igor's symbolic path) remains pointing to the moved folder. After moving the folder, using the unchanged volume refnum and directory ID (in PathInfo or when you use /P=pathName) returns the updated path.

Moving the folder to a different volume actually creates a new folder with new volume refnum and directory IDs, and symbolic paths pointing to or into the moved folder aren't updated. They will be pointing at a deleted folder (they're probably invalid).

Examples

Rename a folder ("move" it to the same folder):

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
```

Rename a folder referred to by only a path:

```
NewPath/O myPath "Macintosh HD:folder"
MoveFolder/P=myPath as "::Renamed Folder"
```

Move a folder from one volume to another. This moves "Macintosh HD:My Folder" inside "Server:My Folder" if "Server:My Folder" already exists:

```
MoveFolder "Macintosh HD:My Folder" as "Server:My Folder"
```

Move a folder from one volume to another. This overwrites "Server:My Folder" (if it existed) with the moved "Macintosh HD:My Folder":

```
MoveFolder/O "Macintosh HD:My Folder" as "Server:My Folder"
```

Move user-selected folder in any folder as "Renamed Folder" into a user-selected folder (possibly the same one):

```
MoveFolder as "Renamed Folder"
```

Move user-selected file in any folder as "Moved Folder" in any folder:

```
MoveFolder/I=3 as "Moved Folder"
```

See Also

MoveFile, **CopyFolder**, **IndexedDir**, **PathInfo**, and **RemoveEnding**. **Symbolic Paths** on page II-30.

MoveString

MoveString *sourceString*, *destDataFolderPath* [*newname*]

The MoveString operation removes the source string variable and places it in the specified location optionally with a new name.

Parameters

sourceString can be just the name of a string variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details

An error is issued if a variable or wave of the same name already exists at the destination.

Examples

```
MoveString :foo:s1,:bar:           // Move string s1 into data folder bar
MoveString :foo:s1,:bar:ss1       // Move string s1 into bar with new name ss1
```

See Also

The MoveVariable, MoveWave, and Rename operations; and Chapter II-8, Data Folders.

MoveSubwindow

MoveSubwindow [*/W=winName*] *key* = (*values*)[, *key* = (*values*)]...

The MoveSubwindow operation moves the active or named subwindow to a new location within the host window. This command is primarily for use by recreation macros; users should use layout mode for repositioning subwindows.

Parameters

fguide=(*gLeft*, *gTop*, *gRight*, *gBottom*)

Specifies the frame guide name(s) to which the outer frame of the subwindow is attached inside the host window.

The frame guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

When the host is a graph, additional standard guides are available for the outer graph rectangle and the inner plot rectangle (where traces are plotted).

See **Details** for standard guide names.

fnum=(*left*, *top*, *right*, *bottom*)

Specifies the new location of the subwindow. The location coordinates of the subwindow sides can have one of two possible meanings:

- 1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.
- 2) When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or pixels for control panels, relative to the top left corner of the host frame.

pguide=(*gLeft*, *gTop*, *gRight*, *gBottom*)

Specifies the guide name(s) to which the plot rectangle of the graph subwindow is attached inside the host window.

Guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

See **Details** for standard guide names.

Flags

/W= winName

Moves the subwindow in the named window or subwindow. When omitted, action will affect the active subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

When moving an exterior subwindow, only the `fnum` keyword may be used. The values are the same as the **NewPanel** /W flag for exterior subwindows.

The names for the built-in guides are as defined in the following table:

	Left	Right	Top	Bottom
Subwindow Frame	FL	FR	FT	FB
Outer Graph Rectangle	GL	GR	GT	GB
Inner Plot Rectangle	PL	PR	PT	PB

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

See Also

The **MoveWindow** operation. Chapter III-4, **Embedding and Subwindows** for further details and discussion.

MoveVariable

MoveVariable *sourceVar*, *destDataFolderPath* [*newname*]

The MoveVariable operation removes the source numeric variable and places it in the specified location optionally with a new name.

Parameters

sourceVar can be just the name of a numeric variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details

An error is issued if a variable or wave of the same name already exists at the destination.

Examples

```
MoveVariable :foo:v1,:bar:           // Move v1 into data folder bar
MoveVariable :foo:v1,:bar:vv1       // Move v1 into bar with new name vv1
```

See Also

The **MoveString**, **MoveWave**, and **Rename** operations; and Chapter II-8, **Data Folders**.

MoveWave

MoveWave *sourceWave*, *destDataFolderPath* [*newname*]

The MoveWave operation removes the source wave and places it in the specified location optionally with a new name.

Parameters

sourceWave can be just the name of a wave in the current data folder, a partial path (relative to the current data folder) and wave name or an absolute path (starting from root) and wave name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details

An error is issued if a variable or wave of the same name already exists at the destination.

Examples

```
MoveWave :foo:w1,:bar:           // Move wave w1 into data folder bar
MoveWave :foo:w1,:bar:ww1       // Move w1 into bar with new name ww1
```

See Also

The **MoveString**, **MoveVariable**, and **Rename** operations; and Chapter II-8, **Data Folders**.

MoveWindow

MoveWindow [*flags*] *left*, *top*, *right*, *bottom*

The MoveWindow operation moves the target or specified window to the given coordinates.

Flags

/C	Moves Command window instead of the target window.
/F	<i>Windows:</i> Moves the Igor Pro application “frame” and the frame is then adjusted so that no part is offscreen. <i>Macintosh:</i> Moves nothing.
/I	Coordinates are in inches.
/M	Coordinates are in centimeters.
/P= <i>procedureTitleAsName</i>	Moves the specified procedure window instead of the target window.
/W= <i>winName</i>	Moves the named window.

Details

Note that neither *winName* nor *procedureTitleAsName* is a string but is the actual window name or procedure window title. If the procedure window’s title (procedure windows don’t have names) has a space in it, use \$ and quotes:

```
MoveWindow/P="$Log Histogram" 0,0,600,400
```

If /W, /F, /C, and /P are omitted, MoveWindow moves the target window.

The coordinates are in points if neither /I nor /M is used.

On Windows, you can use the MoveWindow operation to minimize, restore, or maximize a window by specifying 0, 1, or 2 for all of the coordinates, respectively, as follows:

```
MoveWindow 0, 0, 0, 0      // Minimize target window.
MoveWindow 1, 1, 1, 1      // Restore target window.
MoveWindow 2, 2, 2, 2      // Maximize target window.
```

These special commands are of use on Windows only. Macintosh Igor Pro 3.1 or later ignores these special commands. In earlier versions, the commands set the target window to its smallest allowed size.

See Also

The **MoveSubwindow** and **DoWindow** operations.

NameOfWave

NameOfWave (*wave*)

The NameOfWave function returns a string containing the name of the specified wave.

In a user-defined function that has a parameter or local variable of type WAVE, NameOfWave returns the actual name of the wave identified by the WAVE reference. It can also be used with wave reference functions such as **WaveRefIndexed**.

NameOfWave does not return the full data folder path to the wave. Use **GetWavesDataFolder** for this information.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexed in a loop to act on all waves accessed by WaveRefIndexed, and the loop has incremented beyond the highest valid index.

Examples

```
Function ZeroWave(w)
    Wave w
    w = 0
    Print "Zeroed the contents of", NameOfWave(w)
End
```

See Also

See **WAVE**; the **GetWavesDataFolder** and **WaveRefIndexed** functions; and **Wave Reference Functions** on page IV-143.

NaN

NaN

The NaN function returns the “Not a Number” value according to the IEEE standards.

NeuralNetworkRun

NeuralNetworkRun [/Q/Z] **Input=testWave, WeightsWave1=w1, WeightsWave2=w2**

The NeuralNetworkRun operation uses the interconnection weights generated by NeuralNetworkTrain, and saved in the waves M_Weights1 and M_Weights2, to execute the network for a given input. The input can contain a single run represented by a 1D wave or M runs represented by M columns of a 2D wave. The output of the calculation is saved in the wave W_NNResults or M_NNResults depending on the dimensionality of the input wave. The structure of the network is completely specified by the two weights waves and must match the number of rows in the input wave.

Flags

/Q Suppresses printing information in the History area.
/Z No error reporting.

Key words

Input=testWave Specifies the input to the neural network. *testWave* must be a single or double precision wave containing entries in the range [0,1] and have the correct number of rows to match the weights. Execute the network for multiple runs by using a 2D input wave where each column corresponds to a single run. For a 2D input, the result will be stored in M_NNResults with a corresponding column structure.

WeightsWave1=w1 Specifies the interconnection weights between the input and the hidden layer.

WeightsWave2=w2 Specifies the interconnection weights between the hidden layer and the output.

See Also

The **NeuralNetworkTrain** operation.

NeuralNetworkTrain

NeuralNetworkTrain [/Q/Z] [**keyword = value**]...

The NeuralNetworkTrain operation trains a three-layer neural network. The training produces two 2D waves that store the interconnection weights between the network neurodes. Once you obtain the weights, you can use them with NeuralNetworkRun.

Flags

/Q Suppresses printing information in the History area.
/Z No error reporting.

Parameters

keyword is one of the following:

Input=inWave Specifies the input patterns for training. *inWave* is a 2D wave where each row corresponds to a single training event and each column corresponds to the input values. The number of rows in *inWave* (the number of training sets) and in the output wave must be equal. *inWave* must be single or double precision and all entries must be in the range [0,1].

Iterations=num Specifies the number of iterations. Default is 10000.

MinError=val Terminates training when the total error drops below *val* (default is 1e-8). The total error is normalized, and is defined as the sum of the squared errors divided by the number of training sets times outputs.

Momentum=val Specifies a coefficient for the back-propagation algorithm. This coefficient adds to the change in a particular weight a contribution proportional to the error in a previous iteration. Default momentum is 0.075.

NHidden=num Specifies the number of hidden neurodes. You do not need to use the Structure keyword with NHidden because the network is completely specified by the training waves and NHidden.

NReport=num Specifies over how many iterations (default is 1000) to print the global RMS error to the history window. Ignored with /Q.

NewDataFolder

Output= <i>outWave</i>	Specifies the expected outputs corresponding to the entries in the input wave. The number of rows in <i>outWave</i> (the number of training sets) and in the input wave must be equal. <i>outWave</i> must be single or double precision and all entries must be in the range [0,1].
LearningRate= <i>val</i>	Sets the network learning rate, which is used in the backpropagation calculation. Default is 0.15.
Restart	Allows specification of your own set of weights as the starting values. Use this to run the training and feed the output weights of one training session as the input for the next.
Structure={ <i>Ni, Nh, No</i> }	Specifies the structure of the network. <i>Ni</i> is the number of neurodes at the input, <i>Nh</i> is the number of hidden neurodes, and <i>No</i> is the number of output neurodes. Structure is unnecessary when using NHidden is because the remaining numbers are determined by the sizes of the input and output waves.
WeightsWave1= <i>w1</i>	Specifies the weights for propagation from the first layer to the second. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and inputs and with matching numbers of columns and hidden neurodes.
WeightsWave2= <i>w2</i>	Specifies the weights for propagation from the second to the third layer. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and hidden neurodes and with matching numbers of columns and outputs.

Details

NeuralNetworkTrain is the first half of the implementation of a three-layer neural network in which both in inputs and outputs are taken as normalized quantities in the range [0,1]. Network training is based on back-propagation to iteratively minimize the error between the output and the expected output for any given training set. Training creates in two 2D waves that contain the interconnection weights between the neurodes. M_Weights1 contains the weights between the input layer and the hidden layer and M_Weights2 contains the weights between the hidden layer and the output layer. During the iteration stage, global error information can be printed in the history window.

The algorithm computes the output of the k th neurode by

$$V_k = \left[1 + \exp \left(- \sum_{i=1}^n w_i s_i \right) \right]^{-1}$$

where w_i is the weight corresponding to input i , s_i is the signal corresponding to that input, and n is the number of inputs connected to the neurode.

The total error is defined as the sum (over all training sets and all outputs) of the squared differences between the network outputs and the expected values. The sum is normalized by the product of the number of training sets and the number of outputs. The history reports (see NReport parameter) the square root of the total error (RMS error). The square root of the error computed at the end of the last iteration is stored in the variable V_rms.

See Also

The NeuralNetworkRun operation.

NewDataFolder

NewDataFolder [/O/S] *dataFolderSpec*

The NewDataFolder operation creates a new data folder of the given name.

Parameters

dataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) with name or an absolute path (starting from root) with name. If just a data folder name is used then the new data folder is created in the current data folder.

Flags

/O	No error if a data folder of the same name already exists.
/S	Sets the current data folder to dataFolderSpec after creating the data folder.

Examples

```

NewDataFolder foo           // Creates foo in the current data folder
NewDataFolder :bar:foo      // Creates foo in bar in current data folder
NewDataFolder root:foo      // Creates foo in the root data folder

```

See Also

Chapter II-8, **Data Folders**.

NewFIFO

NewFIFO *FIFOName*

The NewFIFO operation creates a new FIFO.

Details

Useless until channel info is added with **NewFIFOChan**.

An error is generated if a FIFO of same name already exists. *FIFOName* needs to be unique only among FIFOs. You can not overwrite a FIFO.

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-208 and the **NewFIFOChan** operation for more information.

NewFIFOChan

NewFIFOChan [*flags*] *FIFOName*, *channelName*, *offset*, *gain*, *minusFS*, *plusFS*, *unitsStr* [, *vectPnts*]

The NewFIFOChan operation creates a new channel for the named FIFO.

Parameters

channelName must be unique for the specified FIFO.

The *offset*, *gain*, *plusFS*, *minusFS* and *unitsStr* parameters are used when the channel's data is displayed in a chart or transferred to a wave. If given, *vectPnts* must be between 1 and 65535.

Flags

The flags define the type of data to be stored in the FIFO channel:

/B	8-bit signed integer. Unsigned if /U is present.
/C	Complex.
/D	Double precision IEEE floating point.
/I	32-bit signed integer. Unsigned if /U is present.
/S	Single precision IEEE floating point (default).
/U	Unsigned integer data.
/W	16-bit signed integer. Unsigned if /U is present.

As a replacement for the above number type flags you can use */Y=numType* to set the number type as an integer code. See the **WaveType** function for code values. Do not use */Y* in combination with other type flags.

Details

You can not invoke NewFIFOChan while the named FIFO is running.

If you provide a value for *vectPnts*, you will create a channel capable of holding a vector of data rather than just a single data value. When such a channel is used in a Chart, it is displayed as an image using one of the built-in color tables.

Igor scales values in the FIFO channel before displaying them in a chart or transferring them to a wave as follows:

$$\text{scaled_value} = (\text{FIFO_value} - \text{offset}) * \text{gain}$$

Igor uses the *plusFS* and *minusFS* parameters (plus and minus full scale) to set the default display scaling for charts.

The *unitsStr* parameter is limited to a maximum of three characters.

When you transfer a channel's data to a wave, using the **FIFO2Wave** operation, Igor stores the *plusFS* and *minusFS* values and the *unitsStr* in the wave's Y scaling.

NewFreeAxis

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-208 and the **NewFIFO** and **FIFO2Wave** operations for more information.

The **Chart** operation for displaying FIFO data.

NewFreeAxis

NewFreeAxis [*flags*] *axisName*

The NewFreeAxis operation creates a new free axis that has no controlling wave.

Parameters

axisName is the name for the new free axis.

Flags

/L/R/B/T	Specifies whether to attach the free axis to the Left, Right, Bottom, or Top plot edge, respectively. The Left edge is used by default.
/O	Replaces <i>axisName</i> if it already exists, which means any existing axis is marked as truly free.
/W= <i>winName</i>	Draws in the named graph window. <i>winName</i> may also be the name of a subwindow. <i>winName</i> must not conflict with other axis names except when using the /O flag. If /W is omitted, it creates a new axis in the active graph window or subwindow.

Details

A truly free axis does not use any scaling or units information from any associated waves (which need not exist.) You can set the properties of a free axis using **SetAxis** or **ModifyFreeAxis**.

Example

Copy this function to your Procedure window and compile:

```
Function axhook(s)
    STRUCT WMAxisHookStruct &s
    Variable t= s.max
    s.max= s.min
    s.min= t
    return 0
End
```

Now execute this code on the Command line:

```
Make jack=x
Display jack
NewFreeAxis fred
ModifyFreeAxis fred, master=left, hook=axhook
```

See Also

The **SetAxis**, **KillFreeAxis**, and **ModifyFreeAxis** operations.

NewImage

NewImage [*flags*] *matrix*

The NewImage operation creates a new image graph much like “**Display;AppendImage matrix**” except the graph is prepared using a style more appropriate for images. Rather than using preferences, NewImage provides several discrete styles to choose from.

Parameters

matrix is usually an MxN matrix containing image data. See **AppendImage** for details.

Flags

/F	By default, the image is flipped vertically to correspond to normal image orientation. if /F is present then the image is not flipped.
/G= <i>g</i>	<i>g</i> =1: Suppresses the autodetection of three plane images as direct (RGB) color. <i>g</i> = 0: Same as no /G flag (default).
/HIDE= <i>h</i>	Creates a hidden image window or subwindow with <i>h</i> =1. Image is visible with <i>h</i> =0. Use SetWindow to change visibility.

/HOST= <i>hcSpec</i>	Embeds the new image plot in the specified host window or subwindow <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/K= <i>k</i>	Specifies window behavior when closed. <i>k</i> = 0: Normal with dialog (default). <i>k</i> = 1: Kills with no dialog. <i>k</i> = 2: Disables killing.
/N= <i>name</i>	Requests that the created graph have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, <i>S_name</i> is set to the chosen graph name. Use DoWindow/K <i>name</i> to ensure that <i>name</i> is available.
/S= <i>s</i>	Specifies one of several window styles. <i>s</i> = 0: Fills entire window with image. No axes. However, this can result in the lower-right corner not being visible due to the target icon or grow icon (<i>Macintosh</i>). <i>s</i> = 1: Like <i>s</i> = 0 but insets image to avoid corner icon. <i>s</i> = 2: Provides minimalist axes (default).

Details

The graph is sized to make the image pixels a multiple of the screen pixels with the graph size constrained to be not too small and not too large.

If *matrix* appears to fit Igor's standard monochrome category, then explicit mode is set (See **ModifyImage** explicit). To be considered monochrome the wave must be unsigned byte and contain only values of 0, 64 or 255.

Once the graph is created it is a normal graph and has no special properties other than the settings it was created with. Specifically, it will not autosize itself if the dimensions of *matrix* are changed. **NewImage** is just a shortcut for creating a graph window with a style appropriate for images.

This operation is limited in scope by design. If you need to specify the position, size or title, then use the operations **Display** and **AppendImage**.

If the styles provided are not what you desire, touch up an image graph to meet your needs and then use **Capture Graph Prefs** from the **Graphs** menu. Then use "**Display;AppendImage**" rather than **NewImage**.

See Also

The **Display**, **DoWindow**, **AppendImage**, and **ModifyImage** operations.

NewLayout

NewLayout [*flags*] [*as titleStr*]

The **NewLayout** operation creates a page layout.

Unlike the **Layout** operation, **NewLayout** can be used in user-defined functions. Therefore, **NewLayout** should be used in new programming instead of **Layout**.

NewLayout just creates the layout window. Use **AppendLayoutObject** to add objects to the window.

Parameters

The optional *titleStr* parameter is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

Flags

/B=(<i>r,g,b</i>)	Specifies the background color for the layout. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Defaults to white (65535, 65535, 65535).
/C= <i>colorOnScreen</i>	Obsolete; still accepted but has no effect. Prior to Igor Pro 5, this switched the layout display mode between black and white and color, but now layouts are always in color.
/HIDE= <i>h</i>	Shows (<i>h</i> = 1; default) or hides (<i>h</i> = 0) the window.
/K= <i>k</i>	Specifies window behavior when closed. <i>k</i> = 0: Normal with dialog (default). <i>k</i> = 1: Clicking close button kills the layout with no dialog. <i>k</i> = 2: Clicking close button doesn't do anything.

NewMovie

<i>/N=name</i>	Requests that the layout have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, <i>S_name</i> is set to the chosen layout name. Use DoWindow/K name to ensure that <i>name</i> is available. If <i>/N</i> is not used, a name of the form "Layout <i>n</i> ", where <i>n</i> is some integer, is assigned. In a function or macro, the assigned name is stored in the <i>S_name</i> string. This is the name you can use to refer to the page layout window from a procedure. Use the RenameWindow operation to rename the window.
<i>/P=orientation</i>	Sets the orientation of the page in the layout to either Portrait or Landscape (e.g., Layout/P=Landscape). See Details .
<i>/W=(left,top,right,bottom)</i>	Gives the layout window a specific location and size on the screen. Coordinates for <i>/W</i> are in points.

Details

The orientation of the page is controlled by the page setup record associated with the layout. When you create a new layout window, the page setup record comes from your preferred page setup (which you specify via the Capture Layout Prefs dialog) or from a default page setup that Igor creates by calling the current printer driver. When you recreate a layout window using a Window macro, Igor reuses the page setup originally used for the layout window.

See Also

AppendLayoutObject, **DoWindow**, **RemoveLayoutObjects**, and **ModifyLayout**.

NewMovie

NewMovie [*flags*] [*as fileNameStr*]

The NewMovie operation opens a QuickTime movie file in preparation for adding frames via graphs. Your system must be QuickTime capable. On Windows computers, you must have QuickTime 4 or later.

Parameters

The file to be opened is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If NewMovie can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

<i>/F=frameRate</i>	Frames per second between 1 and 60. Defaults to 10.
<i>/I</i>	Presents a standard QuickTime dialog from which you can change the compression settings. The selections you make will become the new default settings but only until you quit Igor Pro.
<i>/L</i>	fLattens movie when done. Use this option when transferring the movie to a different platform. Creates the movie as a single file rather than two files (<i>Windows</i>) or a file with both a data fork and resource fork (<i>Macintosh</i>).
<i>/O</i>	Overwrite existing file, if any.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/S=soundWaveName</i>	Creates and defines the sound track. <i>soundWaveName</i> must exist and must contain values from -128 to +127. Its time/point, as determined by its X scaling, must be between 1.5625×10^{-5} to 2×10^{-4} which correspond to sampling rates of 5000 to 64000 hertz.
<i>/Z</i>	No error reporting; an error is indicated by nonzero value of the variable <i>V_flag</i> . If the user clicks the cancel button in the Save File dialog, <i>V_flag</i> is set to -1.

Details

If either the path or the file name is omitted then NewMovie will bring up a dialog to let you create a movie file. If both are present, NewMovie creates the file automatically. On Macintosh, NewMovie uses a file type

of 'Moov' and a creator type of 'TVOD' whereas on Windows and Mac OS X, movie files are created with a .mov extension.

The target window at the time you invoke NewMovie must be a graph and there can be only one open movie at a time. The graph size should remain constant while adding frames to the movie. The graph (and optional sound wave) are used to determine the size and sound properties only — they are not the first frame.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

See Also

The **AddMovieFrame**, **AddMovieAudio**, **CloseMovie**, and **PlayMovie** operations.

NewNotebook

NewNotebook [*flags*] [*as titleStr*]

The NewNotebook operation creates a new notebook document.

Parameters

The optional *titleStr* is a string containing the title of the notebook window.

Flags

<i>/F=format</i>	<i>format=0</i> : Plain text. <i>format=1</i> : Formatted text. <i>format=-1</i> : Either plain or formatted (default).
<i>/K=k</i>	Specifies window behavior when closed. <i>k=0</i> : Normal with dialog (default). <i>k=1</i> : Clicking the close button kills notebook with no dialog. <i>k=2</i> : Clicking the close button doesn't do anything. <i>k=3</i> : Clicking the close button hides notebook with no dialog.
<i>/N=winName</i>	Sets the notebook's window name to <i>winName</i> .
<i>/V=visible</i>	Specifies whether the notebook window is visible (<i>visible=1</i> ; default) or invisible (<i>visible=0</i>).
<i>/W=(left,top,right,bottom)</i>	Sets window location. Coordinates are in points.

Details

A notebook has a file name, a window name, *and* a window title. In the simplest case these will all be the same.

The file name is the name by which the operating system identifies the notebook once it is saved to disk. When you initially create a notebook, it is not associated with any file. However it still has a file name. This is the name that will be used when the file is saved to disk.

The window name is the name by which Igor identifies the window and therefore the name you specify in operations that act on the notebook.

The window title is what appears in the window's title bar. If you omit the title, NewNotebook uses a default title that is the same as the window name.

If you specify the window name and the notebook format and omit the window title, this is the simplest case. NewNotebook creates the document with no user interaction. The file name, window name and window title will all be the same. For example:

```
NewNotebook/N=Notebook1/F=0
```

If you omit the window name, NewNotebook chooses a default name (e.g., "Notebook0") and presents the standard New Notebook dialog.

If you omit the format or specify a format of -1 (either plain or formatted text), NewNotebook presents the standard New Notebook dialog. For example:

```
NewNotebook/N=Notebook1 // no format specified
```

See Also

The **Notebook** and **OpenNotebook** operations, and Chapter III-1, **Notebooks**.

NewPanel

NewPanel [*flags*] [**as** *titleStr*]

The NewPanel operation creates a control panel window or subwindow, which may contain Igor controls and drawing objects.

Flags

/EXT= <i>e</i>	Creates an exterior subwindow in combination with /HOST. <i>e</i> specifies the host window side location: <i>e</i> =0: Right. <i>e</i> =1: Left. <i>e</i> =2: Bottom. <i>e</i> =3: Top.
/FG=(<i>gLeft, gTop, gRight, gBottom</i>)	Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window. The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name. Guides may override the numeric positioning set by /W.
/FLT[= <i>f</i>]	Creates a floating panel with <i>f</i> =1 or just /FLT. No flag is same as <i>f</i> =0. See Floating Panels .
/HIDE= <i>h</i>	Creates a hidden (<i>h</i> =1) or visible (<i>h</i> =0) panel window or subwindow. Use SetWindow to change visibility.
/HOST= <i>hcSpec</i>	Embeds the new control panel in the specified host window or subwindow <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/I	Sets coordinates to inches.
/K= <i>k</i>	Specifies window behavior when closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills without dialog. <i>k</i> =2: Disables killing. Exterior subwindows never display a dialog when killed.
/M	Sets coordinates to centimeters.
/N= <i>name</i>	Requests that the created panel have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen panel name. Use DoWindow/K <i>name</i> to ensure that <i>name</i> is available. Note that a function or macro with the same name will cause a name conflict.
/NA= <i>n</i>	Sets panel no-activate mode. <i>n</i> =0: Normal (default). <i>n</i> =1: Button click doesn't activate window but click outside of any control does. <i>n</i> =2: No activation even if click is outside controls. Title bar clicks still activate.
/W=(<i>left, top, right, bottom</i>)	Sets the initial coordinates of the panel window (in pixels unless /I or /M are used before /W). When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings: 1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size. 2) When any value is greater than 1, coordinates are taken to be fixed locations measured in pixels relative to the top left corner of the host frame. When the subwindow position is fully specified using guides (using the /HOST or /FG flags), the /W flag may still be used although it is not needed.

Details

If /N is not used, NewPanel automatically assigns to the panel a window name of the form "Panel*n*", where *n* is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the panel from a procedure. Use the **RenameWindow** operation to rename the panel.

Floating Panels

Floating control panels float above all other windows except dialogs. Because floating panels cover up other windows, you should use them sparingly and you should take care to make them small and unobtrusive.

Floating panels are not resizable by default. To allow panel resizing use

```
ModifyPanel fixedSize=0
```

Because floating panels always act as if they are on top, the standard rules for target windows and keyboard focus do not apply.

Normally, a floating panel is never the target window and control procedures will need to explicitly designate the target. But a newly-created floating panel is the default target and will remain so until you execute

```
SetActiveSubwindow _endfloat_
```

It also becomes the default target when the tools are showing and in any non-Operate mode. Similarly, a floating panel with tools not in Operate mode has keyboard focus. To avoid confusion, do not attempt to work on other windows when a floating panel is the default target.

When working with a floating panel, you can show or hide tools or create a recreation macro by Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the panel.

A floating panel does not have keyboard focus. However, a floating panel gains keyboard focus when a control that needs focus is clicked. Focus remains until you press Enter or Escape for a text entry in a setvariable, press Tab until no control has the focus, or until you click outside a focusable control.

On Macintosh, if a floating panel has focus and you activate another window, focus will leave the panel. However on Windows, if a floating panel has focus and you activate another window, the activate sequence will be fouled up leaving the windows in an indeterminate state. Consequently, it is important that you always finish any keyboard interaction started in a floating panel before moving on to other windows. If this can cause confusion, you should not use controls such as SetVariable and ListBox in a floating panel.

On Macintosh, floating panels are hidden when dialogs are up or when Igor Pro is not the front application.

Exterior Subwindows

Exterior subwindows are automatically positioned along the designated side of a host graph window. You can designate fixed sizes or automatic size with minima. Subwindows are stacked beside the designated side in their creation order with the first one closest.

Subwindow dimensions have various meanings depending on their location. Interior values are taken to be additional grout, exterior values are taken to be sizes. For left or right panels, top is taken to be the minimum height and bottom, if not zero, is height. For top and bottom, left is taken to be the minimum width and right, if not zero, is width. Zero values default to 50 for width and height or size of host.

Exterior subwindows are nonresizable by default. Use `ModifyPanel fixedSize=0` to allow manual resizing. If you resize a panel, the original window dimensions are lost. You can also use **MoveSubwindow** to resize the subwindow.

Unlike normal subwindows, exterior subwindows have a tools palette. Click in the window and then choose the Show Tools or Hide Tools menu item.

Exterior subwindows have hook functions independent of the host window.

On Macintosh, exterior subwindows are hidden when Igor Pro is not frontmost.

Examples

In a new experiment, execute these commands on the command line to create two exterior subwindows:

```
Display
// Create panel on right with min height of 200 pixels, width of 100.
NewPanel/HOST=Graph0/EXT=0/W=(0,200,100,0)
// Create another panel on right with grout of 10 and height= width= 100.
NewPanel/HOST=Graph0/EXT=0/W=(10,0,100,100)
```

Now try resizing and moving the graph.

NewPath

For a demonstration of how the various exterior panels work, copy the following code to the procedure window in a new experiment:

```
Function bpNewExSw(ba) : ButtonControl
    STRUCT WMButtonAction &ba
    switch( ba.eventCode )
        case 2:
            ControlInfo/W=$ba.win ckUseRect
            Variable useR= V_Value
            ControlInfo/W=$ba.win popSide
            Variable side= V_Value-1
            ControlInfo/W=$ba.win ckResizable
            Variable resizable= V_Value
            WAVE w=root:epsizes
            if( useR )
                NewPanel/HOST=$ba.win/EXT=(side)/W=(w[0],w[1],w[2],w[3])
            else
                NewPanel/HOST=$ba.win/EXT=(side)
            endif
            if( resizable )
                ModifyPanel fixedSize=0 // default is 1 for floating and exterior sw
            endif
            break
        endswitch
    return 0
End

Window ExSwTest() : Graph
    PauseUpdate; Silent 1 // building window...
    Display /W=(803,377,1158,591)
    Button bNewSW,pos={35,21},size={181,30},proc=bpNewExSw,title="New Exterior Subwindow"
    SetVariable svLeft,pos={118,82},size={96,15},title="left"
    SetVariable svLeft,limits={0,100,1},value= epsizes[0],bodyWidth= 76
    SetVariable svTop,pos={120,97},size={94,15},title="top"
    SetVariable svTop,limits={0,100,1},value= epsizes[1],bodyWidth= 76
    SetVariable svRight,pos={112,113},size={102,15},title="right"
    SetVariable svRight,limits={0,100,1},value= epsizes[2],bodyWidth= 76
    SetVariable svBottom,pos={103,129},size={111,15},title="bottom"
    SetVariable svBottom,limits={0,100,1},value= epsizes[3],bodyWidth= 76
    CheckBox ckUseRect,pos={70,62},size={61,14},title="Use Rect:",value= 0
    PopupMenu popSide,pos={73,149},size={78,20},title="Side"
    PopupMenu popSide,mode=1,popvalue="Right",value= #"\"Right;Left;Bottom;Top\" "
    CheckBox ckResizable,pos={76,176},size={65,14},title="Resizable",value= 0
EndMacro

Function test()
    Make/O/N=4 epsizes=0
    Execute "ExSwTest()"
End
```

After compiling the procedures, execute `test()` on the command line. You can now experiment with different sides and size values.

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

NewPath

NewPath [*flags*] *pathName* [, *pathToFolderStr*]

The NewPath operation creates a new symbolic path name that can be used as a shortcut to refer to a folder on disk.

Parameters

pathToFolderStr is a string containing the path to the folder for which you want to make a symbolic path. *pathToFolderStr* can also point to an alias (*Macintosh*) or shortcut (*Windows*) for a folder.

If you use a full path for *pathToFolderStr*, see **Path Separators** on page III-382 for details on forming the path. If you use a partial path or just a simple name for *pathToFolderStr*, and you use the `/C` flag, a new folder is created relative to the Igor Pro folder. No dialog is presented.

If you omit *pathToFolderStr*, you get a chance to select a folder or create a new folder from a dialog.

Flags

/C	Create the folder specified by <i>pathToFolderStr</i> if it does not already exist.
/M= <i>messageStr</i>	Specifies the prompt message in the dialog.
/O	Overwrites the symbolic path if it exists.
/Q	Suppresses printing path information in the history.
/Z	Doesn't generate an error if the folder does not exist.

Details

Symbolic paths help to isolate your experiments from specific file system paths that contain files created or used by Igor. By using a symbolic path, if the actual location or name of the folder changes, you won't need to change all of your commands. Instead, you need only to change the symbolic path so that it points to the changed folder location.

NewPath sets the variable *V_flag* to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel when you use NewPath to display a choose-folder dialog.

On the Macintosh, pressing Command-Option as the Choose Folder dialog comes up will allow you to choose package folders and folders inside packages.

Examples

```
NewPath Path1, "hd:IgorStuff:Test 1"           // Macintosh
NewPath Path1, "C:IgorStuff:Test 1"           // Windows
```

creates the symbolic path named Path1 which refers to the specified folder (the path's "value"). You can then refer to this folder in many Igor operations and dialogs by using the symbolic path name Path1.

Windows Note:

You can use either the colon or the backslash character to separate folders. However, the backslash character is Igor's escape character in strings. This means that you have to double each backslash to get one backslash like so:

```
NewPath stuff, "C:\\IgorStuff\\Test 1"
```

Because of this complication, it is recommended that you use Macintosh path syntax even on Windows. See **Path Separators** on page III-382 for details.

See Also

The **PathInfo** operation; especially if you need to preset a starting path for the dialog.

NewWaterfall

NewWaterfall [*flags*] *mwave* [*vs {wavex,wavez}*]

The NewWaterfall operation creates a new waterfall plot window or subwindow using each column in the 2D matrix wave, *mwave*, as a waterfall trace.

You can manually set x and z scaling by specifying *wavex* and *wavez* to override the default scalings. Either *wavex* or *wavez* may be omitted by using a *""*.

Flags

/FG=(<i>gLeft, gTop, gRight, gBottom</i>)	Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window. The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name. Guides may override the numeric positioning set by /W.
/HIDE= <i>h</i>	Creates a visible (<i>h</i> =0) or hidden (<i>h</i> =1) waterfall window or subwindow. Use SetWindow to change visibility.
/HOST= <i>hcSpec</i>	Embeds the new waterfall plot in the specified host window or subwindow <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/I	Sets window coordinates to inches.
/K= <i>k</i>	Specifies window behavior when closed.

norm

k =0: Normal with dialog (default).
k =1: Clicking the close button kills the graph with no dialog.
k =2: Clicking the close button doesn't do anything.

/M
Sets window coordinates to centimeters.

/N=*name*
Requests that the created waterfall plot window have this name, if it is not in use. If it is in use, then *name0*, *name1*, etc. are tried until an unused window name is found. In a function or macro, *S_name* is set to the chosen name. Use DoWindow/K *name* to ensure that *name* is available.

/PG=(*gLeft*, *gTop*, *gRight*, *gBottom*)
Specifies the inner plot rectangle of the waterfall plot subwindow inside its host window.
The standard plot rectangle guide names are PL, PR, PT, and PB, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.
Guides may override the numeric positioning set by /W.

/W=(*left*,*top*,*right*,*bottom*)
Specifies window size. Coordinates are in points unless /I or /M is specified before /W.
When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:
1) When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.
2) When any value is greater than 1, coordinates are taken to be fixed locations measured in points relative to the top left corner of the host frame.
When the subwindow position is fully specified using guides (using the /HOST, /FG, or /PG flags), the /W flag may still be used although it is not needed.

Details

The X and Z axes are always at the bottom and left, whereas the Y axis runs at a default 45 degrees along the right-hand side. The angle and length of the Y axis can be changed using the ModifyWaterfall operation. Other features of the graph can be changed using normal graph operations.

Each column from *mwave* is plotted in (and clipped by) a rectangle defined by the X and Z axes with the rectangle displaced along the angled Y axis as a function of the y value.

Except when hidden lines are active, the traces are drawn from back to front.

To modify certain properties of a waterfall plot, you need to use the ModifyWaterfall operation. For other properties, use the usual axis and trace dialogs.

See Also

The DoWindow, ModifyWaterfall, and ModifyGraph operations.

norm

norm(*srcWave*)

The norm function evaluate the norm of *srcWave*. It returns: $\sqrt{\sum \text{abs}(w[i])^2}$.

This function does not support TEXT waves.

note

note(*waveName*)

The note **function** returns a string containing the note associated with the specified wave.

See Also

To create a wave note, use the **Note** operation.

Note

Note [/K/NOCR] *waveName* [, *str*]

The Note **operation** appends *str* to the wave note for the named wave.

Parameters

str is a string expression.

Flags

/K Kills existing note for specified wave.

/NOCR Appends note without a preceding carriage return (\r character). No effect when used with /K.

Examples

```
Note/K wave0           // remove existing note
Note wave0, "This is the first line of the note"
Note wave0, "This is the second line of the note"
Note/K wave0, "This is now the only line of the note"
```

See Also

To get the contents of a wave note, use the **note** function.

Notebook

Notebook *winName*, *keyword=value* [, *keyword=value*]...

The Notebook operation sets various properties of the named notebook window. Notebook also inserts text and graphics. See Chapter III-1, **Notebooks**, for general information on notebooks.

Parameters

The parameters to the Notebook operation are of the form *keyword=value* where *keyword* says what to do and *value* is a parameter or list of parameters. Igor limits the parameters that you specify to legal values before applying them to the notebook.

The parameters are classified into related groups of *keywords*.

See Also

To create or modify a notebook action special character, see **NotebookAction**.

Notebook (Document Properties)

Notebook document property parameters

This section of Notebook relates to setting the document properties of the top notebook.

<i>adopt=a</i>	Adopts a notebook if it is a file saved to disk. Adopting a notebook makes it part of the packed experiment file, which becomes more self-contained; if you send the experiment to a colleague you will not need to send a notebook file. <i>a=0</i> : Checks only whether the notebook is adoptable. Sets <i>V_flag</i> to 0 if the notebook is already adopted or to 1 if it is adoptable. <i>a=1</i> : Adopts the notebook (breaks the link to the file on disk). Sets <i>V_flag</i> to 1 if the adoption succeeded or to 0 if it did not (was already adopted, or some error).
<i>backRGB=(r,g,b)</i>	Sets background color. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<i>defaultTab=dtw</i>	<i>dtw</i> is the default tab width in points.
<i>magnification=m</i>	Specifies the desired magnification in percent (between 25 and 500). Otherwise, <i>m</i> can be one of these special values: <i>m=1</i> : Default magnification. <i>m=2</i> : Fit Width. <i>m=3</i> : Fit Page.
<i>pageMargins={left, top, right, bottom}</i>	Sets page margins in points. <i>left</i> , <i>top</i> , <i>right</i> , and <i>bottom</i> are distances from the respective edges of the physical page.
<i>rulerUnits=r</i>	<i>r=0</i> : Points. <i>r=1</i> : Inches.

Notebook (Miscellaneous)

	<i>r</i> =2: Centimeters.
showRuler= <i>s</i>	Hides (<i>s</i> =0) or shows (<i>s</i> =1) the ruler.
startPage= <i>sp</i>	Sets the starting page number for printing.
statusWidth= <i>sw</i>	Sets the width in points of the status area on the left of the horizontal scroll bar.
userKillMode= <i>k</i>	Specifies notebook window behavior when it is killed.
	<i>k</i> =0: Normal with dialog (default).
	<i>k</i> =1: Clicking the close button kills the notebook with no dialog.
	<i>k</i> =2: Clicking the close button does nothing.
	<i>k</i> =3: Clicking the close button hides the notebook with no dialog.

Notebook (Miscellaneous)

Notebook miscellaneous parameters

This section of Notebook relates to setting miscellaneous properties of the top notebook.

status={ <i>messageStr</i> , <i>flags</i> }	Sets the message in the status area at the bottom left of the notebook window. <i>flags</i> is interpreted bitwise. Message is erased when: bit 0: Selection changes. bit 1: Window is activated. bit 2: Selection is deactivated. bit 3: Document is modified. If all bits are zero, the message stays until a new message comes along. All other bits are reserved for future use and should be zero. See Setting Bit Parameters on page IV-11 for details about bit settings.
updating={ <i>flags</i> , <i>r</i> }	Sets parameters related to the updating of special characters. <i>flags</i> is interpreted bitwise: bit 0: Automatically update time or date special characters periodically. bit 1: Allow updating of special characters via the specialUpdate keyword or via the Special menu. All other bits are reserved for future use and should be zero. See Setting Bit Parameters on page IV-11 for details about bit settings. <i>r</i> is the update rate in seconds for updating time or date special characters. These settings have no effect on the updating of special characters in headers or footers. These characters are always automatically updated when the document is printed. We recommend that you leave automatic updating off (bit 0 of <i>flags</i> parameter) so that updating occurs only via the specialUpdate keyword or via the Special menu.
visible= <i>v</i>	<i>v</i> =0: Hides notebook. <i>v</i> =1: Shows notebook but does not make it top window. <i>v</i> =2: Shows notebook and makes it top window.

Notebook (Paragraph Properties)

Notebook paragraph property parameters

This section of Notebook relates to setting the paragraph properties of the current selection in the top notebook.

The margins, spacing, justification, tabs and rulerDefaults keywords provide control over paragraph properties which are governed by rulers. These keywords, in conjunction with the ruler and newRuler keywords, allow you to set paragraph properties. They are allowed for formatted text notebooks only, not for plain text notebooks.

The ruler keywords are described in detail below. Before we get to the detail, you should understand the different things you can do with rulers.

There are four things you can do with a ruler:

modify it (analogous to manually adjusting a ruler).

redefine it	(analogous to the Redefine Ruler dialog).
create it	(analogous to the Define New Ruler dialog).
apply it	(analogous to selecting a ruler name from Ruler pop-up menu).

Igor's behavior in response to ruler keywords depends on the order in which the keywords appear.

To modify the ruler(s) for the selected paragraph(s), use the margins, spacing, justification, tabs and rulerDefaults keywords *without* using the newRuler or ruler keywords. For example:

```
Notebook Notebook0 tabs={36,144,288},justification=1
```

To redefine an existing ruler, invoke the ruler=*rulerName* keyword *before* any other keywords. For example:

```
Notebook Notebook0 ruler=Ruler1,tabs={36,144,288},justification=1
```

Unlike redefining the ruler manually, when you redefine an existing ruler using ruler=*rulerName*, it does not apply the ruler to the selected text. However, it does update any text governed by the redefined ruler.

To create a new ruler, invoke the newRuler=*rulerName* keyword *before* any other keywords. For example:

```
Notebook Notebook0 newRuler=Ruler1,tabs={36,144,288},justification=1
```

Unlike creating it manually, when you create a new ruler using newRuler=*rulerName*, it does not apply the new ruler to the selected text. If you do not set a particular ruler property when creating a new ruler, the property will be the same as for the Normal ruler. If the specified ruler already exists, newRuler=*rulerName* overwrites the existing ruler.

To apply an existing ruler to the selected text, invoke the ruler=*rulerName* keyword without any other keywords. For example:

```
Notebook Notebook0 ruler=ruler1
```

You and Igor will get confused if you mix ruler keywords with other types of keywords in the same command. It is alright, however to put a selection keyword at the start of the command. Mixing will not cause a crash or any drastic problem but it will likely produce results that you don't understand.

To keep things clear, follow these rules:

- If you use ruler=*rulerName* or newRuler=*rulerName*, put them before any other ruler keywords.
- Do not mix ruler keywords with other kinds, except that it is alright to use the selection keyword at the start of the command.

justification= <i>j</i>	<i>j</i> =0: Left aligned.
	<i>j</i> =1: Center aligned.
	<i>j</i> =2: Right aligned.
	<i>j</i> =3: Fully justified.

margins={*indent*,*left*,*right*}

indent sets the indentation of first line from left page margin.

left sets the paragraph's left margin in points measured from the left page margin.

right sets the paragraph's right margin in points measured from the left page margin.

newRuler=*rulerName* Creates a new ruler with the specified name. If a ruler with this name already exists, it is overwritten.

ruler=*rulerName* Applies the named ruler to the selected text or to redefine the named ruler, as explained above.

rulerDefaults={"fontName", *fSize*, *fStyle*, (*r*,*g*,*b*)}

"fontName" sets the ruler's text font, e.g., "Helvetica".

fSize sets the ruler's text size.

fStyle sets the ruler's text style.

(*r*,*g*,*b*) sets the ruler's text color. *r*, *g*, and *b* are integers from 0 to 65535.

You can only use rulerDefaults if you are redefining an existing ruler, using ruler=*rulerName*, or you are creating a new ruler using newRuler=*rulerName*.

spacing={*spaceBefore*,*spaceAfter*,*lineSpace*}

spaceBefore sets the extra space before paragraph in points.

spaceAfter sets the extra space after paragraph in points.

lineSpace sets the extra space between lines of a paragraph in points.

Notebook (Selection)

`tabs={tabSpec}`

tabSpec is list of tab stops in points added to special values that change the tab stop type.

Tab stops have two parts: the tab stop position and the tab type. Each integer in the list of tabs encodes both of these parts as follows:

The low 11 bits contains the tab stop position in points.

The next two bits are reserved for future use and must be zero.

The high three bits are used to contain the tab type as follows:

left tab	0	
center tab	1	add 1*8192 to tab stop position.
right tab	2	add 2*8192 to tab stop position.
decimal tab	3	add 3*8192 to tab stop position.
comma tab	4	add 4*8192 to tab stop position.

Tabs Example

The following puts a left tab at 1 inch, a center tab at 3 inches and a decimal tab at 5 inches:

Notebook Notebook1 tabs={1*72, 3*72 + 8192, 5*72 + 3*8192}

Notebook (Selection)

Notebook selection parameters

This section of Notebook relates to selecting a range of the content of the top notebook.

`findPicture={graphicNameStr, flags}`

Searches for the picture containing the named graphic (*Macintosh only*) or the next picture if you pass "". Sets *V_flag* to 1 if the picture was found or to 0 if not found.

flags is a bitwise parameter interpreted as follows:

bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting *flags* = 1.

The search is always forward from the end of the current selection to the end of the document.

`findSpecialCharacter={specialCharacterNameStr, flags}`

Searches for the special character with the specified name or the next special character if you pass "". Selects the special character if it is found.

Sets *V_flag* to 1 if the special character was found or to 0 if not. Sets *S_name* to the name of the found special character or to "" if it was not found.

flags is a bitwise parameter interpreted as follows:

bit 0: show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting *flags* = 1.

If *specialCharacterNameStr* is empty (""), the search proceeds from the end of the current selection to the end of the document. Otherwise the search always covers the entire document.

`findText={textToFindStr, flags}`

Searches for the specified text. Sets *V_flag* to 1 if the text was found or to 0 if not found.

textToFindStr is a string expression for the text you want to find. If the text contains a carriage return, Igor considers only the part of the text before the carriage return.

flags is a bitwise integer parameter interpreted as follows:

bit 0: Show selection after the find.

bit 1: Do case-sensitive search.

bit 2: Search for whole words.

bit 3: Wrap around.

bit 4: Search backward.

To set bit 0 and bit 3, use $2^0 + 2^3 = 9$ for *flags*. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

If you are searching forward, the search starts from the end of the current selection. If you are searching backward, the search starts from the start of the current selection.

If you specify "" as the text to search for, it "finds" the current selection. This displays the current selection using `findText={"", 1}`.

`selection={selStart, selEnd}`

selStart and *selEnd* are locations within the document. You can specify these document locations by using the following expressions:

(paragraph, pos)

paragraph and *pos* are numeric expressions.

paragraph is a paragraph number from 0 to *n*-1 where *n* is the number of paragraphs in the document.

pos is a character position from 0 to *n* where *n* is the number of characters in the paragraph. Position 0 is to the left of the first character in the paragraph. Position *n* is to the right of the last character in the paragraph.

`startOfFile`

Start of the document.

`endOfFile`

End of the document.

`startOfParagraph`

Start of current *selStart* paragraph.

`endOfParagraph`

End of current *selStart* paragraph.

`startOfNextParagraph`

Start of paragraph after current *selStart* paragraph.

`endOfNextParagraph`

End of paragraph after current *selStart* paragraph.

`startOfPrevParagraph`

Start of paragraph before current *selStart* paragraph.

`endOfPrevParagraph`

End of paragraph before current *selStart* paragraph.

`endOfChars`

Just before the carriage return of current *selStart* paragraph.

Igor clips the specified locations to legal values. It also sets the *V_flag* variable to 0 if the *selStart* location that you specified was valid, to 1 if the start paragraph was out of bounds and to 2 if the start position was out of bounds. You can use the `startOfNextParagraph` keyword to step through the document one paragraph at a time. When *V_flag* is nonzero, you are at the end of the document.

The terms *next* and *prev* are relative to the paragraph containing the start of the selected text before the selection keyword was invoked.

Selection Examples

Following are some examples of setting the selection:

```
// select all text in notebook
Notebook Notebook1 selection={startOfFile, endOfFile}

// move selection to the end of the notebook
Notebook Notebook1 selection={endOfFile, endOfFile}

// select all of paragraph 3
Notebook Notebook1 selection={{3,0}, {4,0}}

// select all of current paragraph except for trailing CR, if any
Notebook Notebook1 selection={startOfParagraph, endOfChars}

// find the first occurrence of "Hello" in the document
Notebook Notebook1 selection={startOfFile, startOfFile}, findText={"Hello", 1}

// find the first picture in the document
Notebook Notebook1 selection={startOfFile, startOfFile}, findPicture={"", 1}
```

See Also

The **GetSelection** operation to "copy" the selection.

Notebook (Text Properties)

Notebook text property parameters

This section of Notebook relates to setting the text properties of the current selection in the top notebook.

`font="fontName"`

"fontName" is the name of the font. Use "default" to specify the paragraph's ruler font.

If you specify an unavailable font, it does nothing. This is so that, when you share procedures with a colleague, using a font that the colleague does not have will not

Notebook (Writing Graphics)

	cause your procedures to fail. The downside of this behavior is that if you misspell a font name you will get no error message.
fSize= <i>fontSize</i>	Text size from 3 to 32000 points. Use -1 to specify the paragraph's ruler size.
fStyle= <i>fontStyle</i>	A binary coded integer with each bit controlling one aspect of the text style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>). Use -1 to specify the paragraph's ruler style. To set bit 0 and bit 1 (bold italic), use $2^0 + 2^1 = 3$ for <i>fontStyle</i> . See Setting Bit Parameters on page IV-11 for details about bit settings.
textRGB=(<i>r,g,b</i>)	Specifies text color. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. (0, 0, 0) specifies black. (65535, 65535, 65535) specifies white.
vOffset= <i>v</i>	Sets the vertical offset in points (positive offset is down, negative is up). Use this to create subscripts and superscripts. vOffset is allowed for formatted text files only, not for plain text files.

Notebook (Writing Graphics)

Writing notebook graphics parameters

This section of Notebook relates to inserting graphics at the current selection in the top notebook.

These graphics keywords are allowed for formatted text files only, not for plain text files.

convertToPNG= <i>x</i>	Converts all pictures in the current selection to cross-platform PNG format. If the picture is already PNG, it does nothing. <i>x</i> is the resolution expansion factor, an integer from 1 to 16 times screen resolution. <i>x</i> is clipped to legal limits.
frame= <i>f</i>	<i>f</i> =0: No frame. <i>f</i> =1: Single frame. <i>f</i> =2: Double frame. <i>f</i> =3: Triple border. <i>f</i> =4: Shadow frame.
picture={ <i>objectSpec</i> , <i>mode</i> , <i>flags</i> }	Inserts a picture based on the specified object. <i>objectSpec</i> is usually just an object name, which is the name of a graph, table, page layout or picture. See further discussion below. <i>mode</i> controls what happens when you insert a picture of a graph, table or page layout window. It does not affect insertions of pictures from the picture gallery. <i>mode</i> specifies the format of the graph, table, or page layout picture as follows:

<i>mode</i>	Macintosh	Windows
-5	PNG	PNG
-4	HiRes bitmap	Device-independent bitmap
-2	HiRes PICT	Enhanced metafile
-1	PostScript PICT	Enhanced metafile
0	PostScript PICT	Enhanced metafile
1	1X PICT	Enhanced metafile
2	2X PICT	Enhanced metafile
4	4X PICT	Enhanced metafile
8	8X PICT	Enhanced metafile

On Macintosh, *mode* 0 is the same as *mode* -1 except that Igor uses QuickDraw to draw text.

If you expect to print on a PostScript printer, *mode*=-1 is the recommended choice. If you expect to print on a non-PostScript printer, *mode*=-2 is the recommended choice. *mode*=-5 is the only mode that produces a picture that is viewable on both platforms. However, this does not produce a high resolution picture. The PNG is created at screen resolution.

See Chapter III-5, **Exporting Graphics (Macintosh)**, or Chapter III-6, **Exporting Graphics (Windows)**, for further discussion of these formats. The PNG format is discussed further in **Picture Compatibility** on page III-379.

flags is interpreted bitwise:

bit 0: 0 for black and white, 1 for color.

For color, set *flags* = $2^0 = 1$. All other bits are reserved for future use and should be zero. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

scaling=*{h, v}* Sets the horizontal(*h*) and vertical (*v*) scaling of the picture in percent.

You may include a coordinate specification after the object name in *objectSpec*. For example:

```
Notebook Notebook1 picture={Layout0(100, 50, 500, 700), 1, 1}
```

The coordinates are in points. A coordinate specification of (0, 0, 0, 0) behaves the same as no coordinate specification at all.

If the object is a graph, the coordinate specification determines the width and height of the graph. If you omit the coordinate specification, Igor takes the width and height from the graph window.

If the object is a layout, the coordinate specification identifies a section of the layout. If you omit the coordinate specification, Igor selects a section of the layout that includes all objects in the layout plus a small margin.

For any other kind of object, Igor ignores the coordinate specification if it is present.

The scaling and frame keywords affect the selected picture, if any. If no picture is selected, they affect picture insertion. For example, this command inserts a picture of Graph0 with 50% scaling and a double frame:

```
Notebook Test1 scaling={50, 50}, frame=2, picture={Graph0, 1, 1}
```

If no picture is selected and no picture is inserted, scaling and frame have no effect.

Notebook (Writing Headers and Footers)

Writing notebook headers and footers

There is currently no way to set headers and footers except manually through the Document Settings dialog. You may be able to use stationery files to create files with specific headers and footers.

Notebook (Writing Special Characters)

Writing special character parameters

This section of Notebook relates to inserting special characters at the current selection in the top notebook. To insert a notebook action, see **NotebookAction**.

The special characters are page break, short date, long date, abbreviated date and time. They act in some respects like a single character but have special properties. You can insert the special characters using the *specialChar* keyword.

The *specialChar* keyword is allowed for formatted text files only, not for plain text files.

Other special characters are allowed in headers and footers only and you can not insert them in a document using the *specialChar* keyword. These are window title, page number and total pages.

The special characters other than page break character are dynamic and update periodically.

specialChar=*{type, flags, optionsStr}*

type is the special character type as follows:

- 1: Page break.
- 2: Short date.
- 3: Long date.

4: Abbreviated date.
5: Time.

flags is reserved for future use. You should pass 0 for *flags*.
optionsStr is reserved for future use. You should pass "" for *optionsStr*.

`specialUpdate=flags` Updates special characters in the notebook (*Macintosh only* feature).
flags is interpreted bitwise:

- bit 0: 0 to update all special characters.
1 to update special characters in the selected text.
- bit 1: If 0 and updating for the document is disabled, it generates an error.
If 1, updates regardless of whether updating is enabled or not. Use this at your own risk!

All other bits are reserved for future use and should be zero. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

On Macintosh, the `specialUpdate` keyword can update pictures of graphs, tables, and page layouts that were created from windows in the current experiment.

See Also

Chapter III-1, **Notebooks**. The **NewNotebook**, **NotebookAction**, and **OpenNotebook** operations; the **SpecialCharacterInfo** and **SpecialCharacterList** functions.

Notebook (Writing Text)

Writing notebook text parameters

This section of Notebook relates to inserting text at the current selection in the top notebook.

`text=textStr` Inserts the text at the current selection.
Before the text is inserted, Igor converts escape sequences in *textStr* as described in **Escape Characters in Strings** on page IV-13.
Then, it checks for illegal characters. The only character code that is illegal is zero (ASCII NUL character). If it finds an illegal character, Igor generates an error and does not insert the text.

NotebookAction

NotebookAction [/W=*winName*] **keyword** = **value** [, **keyword** = **value** ...]

The NotebookAction operation creates or modifies an "action" in a notebook. A notebook action is an object that executes commands when clicked.

See Chapter III-1, **Notebooks**, for general information about notebooks.

Parameters

The parameters are in *keyword=value* format. Parameters are automatically limited to legal values before being applied to the notebook.

`bgRGB=(r, g, b)` Specifies the action background color. *r*, *g*, and *b* are values from 0 to 65535.
`commands=str` Specifies the command string to be executed when clicking the action. For multiline commands, add a carriage return (\r) between lines.
`enableBGRGB=enable` Uses the background color specified by `bgRGB` (*enable*=1). Background color is ignored for *enable*=0.
`frame=f` Specifies the frame enclosing the action.
f=0: No frame.
f=1: Single frame.
f=2: Double frame.
f=3: Triple border.
f=4: Shadow frame.
`helpText=helpTextStr` Specifies the help string for the action. The text is limited to 255 characters. On Macintosh, help appears when the cursor is over the action after choosing

	Help→Show Igor Tips. On Windows, help appears in the status line when the cursor is over the action.
<code>ignoreErrors=ignore</code>	Controls whether an error dialog will appear (<i>ignore</i> =0) or not (<i>ignore</i> is nonzero) if an error occurs while executing the action commands.
<code>linkStyle=linkStyle</code>	Controls the action title text style. If <i>linkStyle</i> =1, the style is the same as a help link (blue underlined). If <i>linkStyle</i> =0, the style properties are the same as the preceding text.
<code>name=name</code>	Specifies the name of the new or modified notebook action. This is a standard Igor name. See Standard Object Names on page III-399 for details.
<code>padding={leftPadding, rightPadding, topPadding, bottomPadding, internalPadding}</code>	Sets the padding in points. <i>internalPadding</i> sets the padding between the title and the picture when both elements are present.
<code>picture=name</code>	Specifies a picture for the action icon. <i>name</i> is the name of a picture in the picture collection (see Pictures on page III-405). If <i>name</i> is null (\$""), it clears the picture parameter.
<code>procPictName=name</code>	Specifies a Proc Picture for the action icon (see Proc Pictures on page IV-44). <i>name</i> is the name of a Proc Picture or null (\$" ") to clear it. This will be a name like <code>ProcGlobal#myPictName</code> or <code>MyModuleName#myPictName</code> . If you use a module name, the Proc Picture must be declared static. If you specify both picture and <code>procPictName</code> , picture will be used.
<code>quiet=quiet</code>	Displays action commands in the history area (<i>quiet</i> =0), otherwise (<i>quiet</i> =1) no commands will be recorded.
<code>scaling={h, v}</code>	Scales the picture in percent horizontally, <i>h</i> , and vertically, <i>v</i> .
<code>showMode=mode</code>	Determines if the title or picture are displayed. <code>mode=1:</code> Title only. <code>mode=2:</code> Picture only. <code>mode=3:</code> Picture below title. <code>mode=4:</code> Picture above title. <code>mode=5:</code> Picture to left of title. <code>mode=6:</code> Picture to right of title. Without a picture specification, the action will use title mode regardless of what you specify.
<code>title=titleStr</code>	Sets the action title to <i>titleStr</i> , which is limited to 255 characters.

Flags

<code>/W= winName</code>	Specifies the notebook window of interest. If <code>/W</code> is omitted, NotebookAction acts on the top notebook window.
--------------------------	---

Examples

```
String nb = WinName(0, 16, 1)           // Top visible notebook
NotebookAction name=Action0, title="Beep", commands="Beep" // Create action
NotebookAction name=Action0, enableBGRGB=1, padding={4,4,4,4,4}
Notebook $nb, findSpecialCharacter={"Action0",1}           // Select action
Notebook $nb, frame=1                                     // Set frame
```

See Also

Chapter III-1, **Notebooks**.

The **Notebook**, **NewNotebook**, and **OpenNotebook** operations; the **SpecialCharacterInfo** and **SpecialCharacterList** functions.

num2char

num2char (*num*)

The num2char function returns a string containing one character whose ASCII code is *num*.

Examples

```
Print num2char(65)      // prints A
Print num2char(97)      // prints a
```

num2istr

num2istr (*num*)

The num2istr function returns a string representing *num* after rounding to the nearest integer.

num2str

num2str (*num*)

The num2str function returns a string representing the number *num*.

Precision is limited to only five decimal places. This can cause unexpected and confusing results. For this reason, we recommend that you use **num2istr** or **sprintf** for better control of the format and precision of the number conversion.

NumberByKey

NumberByKey(*keyStr*, *kwListStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]]])

The NumberByKey function returns a numeric value extracted from *kwListStr* based on the specified key contained in *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use NumberByKey to extract a numeric value from a strings containing "key1=value1;key2=value2;" style lists such as those returned by functions like **AxisInfo** or **TraceInfo**.

If the key is not found or if any of the arguments is "" or if the conversion to a number fails then it returns NaN.

keySepStr, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

Details

keyStr is limited to 255 characters.

kwListStr is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next *listSepStr* is converted to the returned number.

kwListStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

Examples

```
Print NumberByKey("AKEY", "AKEY:123;") // prints 123
Print NumberByKey("BKEY", "AKEY=123;Bkey=456;", "=") // prints 456
Print NumberByKey("KEY2", "KEY1=123,KEY2=999,", "=", ",") // prints 999
Print NumberByKey("ckey", "CKEY=123;ckey=456;", "=", ";") // prints 123
Print NumberByKey("ckey", "CKEY=123;ckey=456;", "=", ";", 1) // prints 456
```

See Also

The **StringByKey**, **RemoveByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

numpnts

numpnts (*waveName*)

The numpnts function returns the total number of data points in the named wave. To find the number of elements in a dimension of a multidimensional wave, use the **DimSize** function.

numtype

numtype(*num*)

The numtype function returns a number which indicates what kind of value *num* contains.

Details

If *num* is a real number, numtype returns a real number whose value is:

- 0: If *num* contains a normal number.
- 1: If *num* contains +/-INF.
- 2: If *num* contains NaN.

If *num* is a complex number, numtype returns a complex number in which the real part is the number type of the real part of *num* and the imaginary part is the number type of the imaginary part of *num*.

NumVarOrElseDefault

NumVarOrElseDefault(*pathStr*, *defVal*)

The NumVarOrElseDefault function checks to see if the *pathStr* points to a numeric variable. If the numeric variable exists, NumVarOrElseDefault returns its value. If the numeric variable does not exist, it returns *defVal* instead.

Details

NumVarOrElseDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. String variables use the corresponding numeric function,

StrVarOrElseDefault.

Examples

```
Macro foo(nval,sval)
  Variable nval=NumVarOrElseDefault("root:Packages:mypack:nvalSav",2)
  String sval=StrVarOrElseDefault("root:Packages:mypack:svalSav","Hi")

  String dfSav= GetDataFolder(1)
  NewDataFolder/O/S root:Packages
  NewDataFolder/O/S mypack
  Variable/G nvalSav= nval
  String/G svalSav= sval
  SetDataFolder dfSav
End
```

NVAR

NVAR [*/C*][*/Z*] *localName* [= *pathToVar*][, *localName1* [= *pathToVar1*]]...

NVAR is a reference that creates a local reference to a global numeric variable accessed in a user-defined function.

The NVAR reference is required when you access a global numeric variable in a function. At compile time, the NVAR statement specifies the local name referencing a global numeric variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global numeric variable must exist when the NVAR statement is executed.

When *localName* is the same as the global numeric variable name and you want to reference a global variable in the current data folder, you can omit *pathToVar*. Prior to Igor Pro 4.0, *pathToVar* was always required.

pathToVar can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-48).

If the global variable may not exist at runtime, use the */Z* flag and call **NVAR_Exists** before accessing the variable. The */Z* flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

```
NVAR/Z nv=<pathToPossiblyMissingNumericVariable>
if( NVAR_Exists(nv) )
  <do something with nv>
endif
```

Note that to create a global numeric variable, you use the **Variable**/G operation.

Flags

/C Variable is complex.

/Z Ignores variable reference checking failures.

See Also

NVAR_Exists function and **Runtime Lookup of Globals** on page IV-50.

Accessing Global Variables and Waves on page IV-49.

Converting a String into a Reference Using \$ on page IV-48.

NVAR_Exists

NVAR_Exists(name)

The **NVAR_Exists** function returns one if specified NVAR reference is valid or zero if not. Used only in user-defined functions.

For example if, in a user function, you have:

```
NVAR var1= MyGlobalVar  
print NVAR_Exists(var1)
```

will print 1 if MyGlobalVar is present in the current data folder.

WaveExists, **SVAR_Exists**, and **Runtime Lookup of Globals** on page IV-50.

Open

Open [flags] refNum [as fileNameStr]

The **Open** operation can, depending on the flags passed to it:

1. Display a Save File dialog (/D flag).
2. Create a new file or overwrite an existing file to write results to.
3. Open an existing file to append results to (/A flag).
4. Display an Open File dialog (/R/D flags).
5. Open an existing file to read data from (/R flag).
6. Test if a file exists (/Z=1 flag).

Parameters

refNum is the name of a numeric variable to contain the file reference number. You use this number with the **FReadLine**, **FStatus**, **FSetPos**, **FBinWrite**, **FBinRead**, **fprintf**, and **wfprintf** operations to read from or write to the file. When you're finished, use the file reference number with the **Close** operation to close the file. The file reference number is not returned when the /D flag is used.

The following discussion of the *pathName* and *fileNameStr* parameters applies when you are attempting to open a file for reading or writing (cases 2, 3, and 5 above).

The file to be opened for reading or writing is specified by a combination of the *pathName* parameter and the *fileNameStr* parameter. There are three ways to specify the file of interest:

- A. Use /P=*pathName* and *fileNameStr*, where *pathName* is an Igor symbolic path (see **Symbolic Paths** on page II-30) that points to the folder containing the file and *fileNameStr* is the name of the file.
- B. Use /P=*pathName* and *fileNameStr*, where *pathName* is an Igor symbolic path that points to the folder containing the file and *fileNameStr* is a partial path starting from the folder and leading to the file.
- C. Use just *fileNameStr*, where *fileNameStr* is a full path to the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you omit as *fileNameStr* or if the *pathName* and *fileNameStr* parameters do not fully specify the location of the file, then Igor will display a Save File or Open File dialog to allow the user to choose a file.

In cases 1 and 4 above, you are not trying to actually open a file but rather you just want to display a dialog allowing the user to choose a file which you will open later. In these cases, the *pathName* and *fileNameStr* parameters work the same, except that Igor always displays a dialog and does not actually open the file.

In case 6 above, you want to find if a file exists or not and you want to open it if it does exist. In this case, the *pathName* and *fileNameStr* parameters work the same, except that Igor never displays a dialog.

Flags

<code>/A</code>	Opens file for appending.
<code>/C=creatorStr</code>	Specifies the file creator code. This is meaningful on Macintosh only and is ignored on Windows. For opening an existing file, creator defaults to "?????" which means "any creator". For creating a new file, <i>creatorStr</i> defaults to "IGR0" which is Igor's creator code.
<code>/D</code>	<p>Dialog only.</p> <p>Open presents a dialog from which the user can select a file but does not actually open the file. Instead, Open puts the full file name of the file into the string variable <i>S_fileName</i>. You can save this in your own string variable for later use. If the user clicks the Cancel button, <i>S_fileName</i> is set to an empty string.</p> <p>Use Open/D/R to bring up an open file dialog and Open/D to bring up a save-file dialog.</p> <p>Do not use /Z with /D.</p>
<code>/M=messageStr</code>	Prompt message text in the dialog used to select the file, if any.
<code>/P=pathName</code>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<code>/R</code>	The file is opened read only.
<code>/T=typeStr</code>	<p>Specifies the types of files that can be opened via the dialog when Open presents an Open File dialog (because the /D/R flags were used or because /R was used and the file to be opened was not fully specified by the <i>pathName</i> and <i>fileNameStr</i> parameters).</p> <p>When Open does not present a dialog and /R was not used, /T specifies the type of file to be created.</p> <p><i>typeStr</i> may contain either Macintosh file types (e.g., "TEXT") or file name extensions (e.g., ".txt").</p> <p>When an Open File dialog is displayed, the pattern "?????" means "any type of file".</p> <p><i>typeStr</i> may contain multiple file types or extensions (e.g., "TEXTSPSF?????" or ".txt.eps????"). Each file type or extension must be exactly four characters in length. Consequently the /T flag can accommodate only three-character file name extensions.</p> <p>If /T is omitted, Open defaults to "TEXT".</p> <p>Igor maps Macintosh file types to extensions. For example, if you specify /T="TEXT", you can open files with the extension ".txt". Igor does similar mappings for other extensions. See File Types and Extensions on page III-387 for details.</p>
<code>/Z[=z]</code>	<p>Prevents aborting of procedure execution if an error occurs, for example if the procedure tries to open a file that does not exist for reading. Use /Z if you want to handle this case in your procedures rather than having execution abort.</p> <p>When using /Z, /Z=1, or /Z=2, <i>V_flag</i> is set to 0 if no error occurred or to a nonzero value if an error did occur.</p> <p>Do not use /Z with /D.</p> <p>/Z=0: Same as no /Z.</p> <p>/Z=1: Suppresses normal error reporting. When used with /R, it opens the file if it exists. /Z alone has the same effect as /Z=1.</p> <p>/Z=2: Suppresses normal error reporting. When used with /R, it opens the file if it exists or displays a dialog if it does not exist.</p>

Details

When Open returns, if a file was actually opened, the *refNum* parameter will contain a file reference number that you can pass to other operations to read or write data. If the file was not opened because of an error or because the user cancelled, *refNum* will be unchanged.

If you use /R (open for read) or /A (open for append), Open will open an existing file. If you omit these flags, Open will create and open a file. See **Warning**.

If both /R and /A are omitted then Open creates and opens a file. If the specified file does not already exist, Open creates it, using the specified type and creator codes, and opens it for writing. If the file does already exist then Open opens it and sets the file mark to the start of the file. The file mark determines where in the file data will be written. Thus, you will be overwriting existing data in the file. If the file already exists and its type is not the same as the specified file type, Open will generate an error.

Warning: If you open an existing file for writing (you do not use /R) then you will overwrite or truncate existing data in the file. To avoid this, open for read (use /R) or open for append (use /A) or move the file mark to the end of the file (using the FSetPos operation).

If /R is present then the file is opened for reading and must already exist.

If /A is present, the file, which must already exist, is opened for appending. Open opens it and then moves the file mark to the end of the file so that writes add to data that was already there.

On the Macintosh, the Open File dialog presented when you use Open/R or Open/A will always include All Documents in the Show Files of Type menu. Selecting All Documents will allow you to select any file; in addition you can navigate into packages (folders that appear in the Finder to be files).

On the Macintosh, when you use Open without the /A or /R flags, press Command-Option as the dialog is presented in order to navigate into packages. Be careful not to damage the package!

Variables

The Open operation returns information in the following variables:

V_flag	Set only when the /Z flag is used. V_flag is set to zero if the file was opened, to -1 if Open displayed a dialog and the user canceled, and to some nonzero value if an error occurred, such as the /R or /A flag was used, and the specified file does not exist.
S_fileName	Stores the full path to the file that was opened. If an error occurred or if the user canceled, it is set to an empty string.

When using /D, the value of V_flag is undefined. Do not use /Z with /D. Use S_fileName to determine if the user selected a file or canceled.

Examples

This example function illustrates using Open to open a text file from which data will be read. The function takes two parameters: an Igor symbolic path name and a file name. If either of these parameters is an empty string, the Open operation will display a dialog allowing the user to choose the file. Otherwise, the Open operation will open the file without displaying a dialog.

```
Function DemoOpen(pathName, fileName)
    String pathName      // Name of symbolic path or "" for dialog.
    String fileName      // File name, partial path, full path or "" for dialog.
    Variable refNum
    String str

    // Open file for read.
    Open/R/Z=2/P=$pathName refNum as fileName
    // Store results from Open in a safe place.
    Variable err = V_flag
    String fullPath = S_fileName

    if (err == -1)
        Print "DemoOpen canceled by user."
        return -1
    endif

    if (err != 0)
        DoAlert 0, "Error in DemoOpen"
        return err
    endif

    Printf "Reading from file \"%s\". First line is:\r", fullPath
    FReadLine refNum, str      // Read first line into string variable
    Print str
    Close refNum
    return 0
End
```

For an example that uses Open to load data from a text file, see the Load File Demo example in "Igor Pro Folder:Examples:Programming".

The next example shows how to use Open/D/R to display an open file dialog. This function returns the full path to the file selected by the user or an empty string ("") if the user cancels.

```
Function/S DoOpenFileDialog()
    Variable refNum
    String message = "Select a file"
    String outputPath
```

```

    Open/D/R/M=message refNum
    outputPath = S_fileName
    return outputPath          // Will be empty if user canceled
End

```

OpenNotebook

OpenNotebook [*flags*] [*fileNameStr*]

The OpenNotebook operation opens a file for reading or writing as an Igor notebook.

Unlike the Open operation, OpenNotebook will not create a file if the specified file does not exist. To create a new notebook, use the **NewNotebook** operation.

Parameters

The file to be opened is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

<i>/A</i>	Moves the notebook's selection to the end of the notebook.
<i>/K=k</i>	Specifies window behavior when closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Clicking the close button kills the notebook with no dialog. <i>k</i> =2: Clicking the close button doesn't do anything. <i>k</i> =3: Clicking the close button hides the notebook with no dialog.
<i>/M=messageStr</i>	Prompt message text in the dialog used to find the file, if any.
<i>/N=winName</i>	Specifies the window name to be assigned to the new notebook. If omitted, it assigns a name like "Notebook0".
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/R</i>	Opens the file as read only.
<i>/T=typeStr</i>	Specifies the type or types of files that can be opened.
<i>/V=visible</i>	Hides (<i>visible</i> = 0) or shows (<i>visible</i> = 1; default) the notebook.
<i>/Z</i>	Suppresses error generation. Use this to check if a file exists. If you use <i>/Z</i> , OpenNotebook sets the variable <i>V_flag</i> to 0 if the notebook was opened or to nonzero if there was an error, usually because the specified file does not exist.

Details

The */A* (append) flag has no effect other than to move the selection to the end of the notebook after it is opened.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

The */T=typeStr* flag affects only the dialog that OpenNotebook presents if you do not specify a path and filename. The dialog presents only those files whose type is specified by */T=typeStr*. There are two file types that are allowed for notebooks: 'TEXT' which is a plain text file and 'WMT0' which is a WaveMetrics formatted text file. Therefore, the file type, if you use it, should be either "TEXT" or "WMT0". If */T=typeStr* is missing, it defaults to "TEXTWMT0". This opens either type of notebook file. On Windows, Igor considers files with ".txt" extensions to be of type TEXT and considers files with ".ifn" to be of type WMT0. See **File Types and Extensions** on page III-387 for details.

See Also

The **Notebook** and **NewNotebook** operations, and Chapter III-1, **Notebooks**.

OpenProc

OpenProc [*flags*] [*fileNameStr*]

The OpenProc operation opens a file as an Igor procedure file.

Note: This operation is used automatically to open procedure files when you open an Igor experiment. You can invoke OpenProc only from the command line. Do not invoke it from a procedure. To open procedure files from a procedure or from a menu definition, use the Execute/P operation.

Parameters

The file to be opened is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/A	Moves the procedure window's selection to the end of the window.
/M= <i>messageStr</i>	Prompt message text in the dialog used to find the file, if any.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/R	The file is opened read only.
/T= <i>typeStr</i>	Specifies the type or types of files that can be opened.
/V= <i>visible</i>	Hides (<i>visible</i> = 0) or shows (<i>visible</i> = 1; default) the procedure window.
/Z	Suppresses error generation if the specified file does not exist.

Details

The /A (append) flag has no effect other than to move the selection to the end of the procedure file after it is opened.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

OpenProc automatically opens procedure files when you open an Igor experiment. Normally, you will have no use for it. You can not open a procedure file while procedures are executing. Thus, you can't invoke OpenProc from within a procedure. You can only invoke it from the command line or from a user menu definition (actually, you may get away with it in a macro, but it's not recommend).

Chapter III-13, **Procedure Windows**.

The **Execute** operation.

OperationList

OperationList(*matchStr*, *separatorStr*, *optionsStr*)

The OperationList function returns a string containing a list of internal (built-in) or external operation names corresponding to *matchstr*.

Parameters

Only operation names that match *matchStr* string are listed. Use "*" to match all names. See **WaveList** for examples.

The first character of *separatorStr* is appended to each operation name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-144 for details).

Use *optionsStr* to further qualify the list of operations. *optionsStr* is a (case-insensitive) string containing one of these values:

"internal" Restricts the list to built-in operations.

"external" Restricts the list to external operations (see **Igor Extensions** on page III-407).

Any other value for *optionsStr* ("all" is recommended) will return both internal and external operations.

See Also

The **DisplayProcedure** operation and the **FunctionList**, **MacroList**, **StringFromList**, and **WinList** functions.

Optimize**Optimize** [*flags*] *funcspec*, *pWave*

The Optimize operation determines extrema (minima or maxima) of a specified nonlinear function. The function must be defined in the form of an Igor user function.

Use the first form for univariate functions (one dimensional functions; functions taking just one variable). Use the second form with multivariate functions (functions in more than one dimension; functions of more than one variable).

Optimize uses Brent's method for univariate functions. For multivariate functions you can choose several variations of quasi-Newton methods or simulated annealing.

Flags

<i>/A</i> [= <i>findMax</i>]	Finds a maximum (<i>/A</i> =1 or <i>/A</i>) or minimum (<i>/A</i> =0 or no flag).
<i>/D</i> = <i>nDigits</i>	Specifies the number of good digits returned (default is 15) by the function being optimized. If you use <i>/X=xWave</i> with a single-precision wave, the default is seven. Ignored with simulated annealing (<i>/M</i> = <i>{3,0}</i>).
<i>/DSA</i> = <i>destWave</i>	Sets a wave to track the current best model only found with simulated annealing (<i>/M</i> = <i>{3,0}</i>). <i>destWave</i> must have the same number of points as the X vector.
<i>/F</i> = <i>trustRegion</i>	Sets the initial trust region when <i>/M</i> = <i>{1 or 2, ...}</i> with multivariate functions. The value is a scaled step size (see Multivariate Details). After the first iteration the trust region is adjusted according to conditions. Ignored with simulated annealing (<i>/M</i> = <i>{3,0}</i>).
<i>/H</i> = <i>highBracket</i> <i>/L</i> = <i>lowBracket</i>	Find the extrema of a univariate function. <i>lowBracket</i> and <i>highBracket</i> are X values on either side of the extreme point. An extreme point is found between the bracketing values. If <i>lowBracket</i> and <i>highBracket</i> are equal, Optimize adds 1.0 to <i>highBracket</i> before looking for an extreme point. Default values for <i>lowBracket</i> and <i>highBracket</i> are zero. Thus, if neither <i>lowBracket</i> nor <i>highBracket</i> is present, this is the same as <i>/L</i> =0/ <i>H</i> =1. Ignored with simulated annealing (<i>/M</i> = <i>{3,0}</i>).
<i>/I</i> = <i>maxIters</i>	Sets the maximum number of iterations in searching for an extreme point to <i>maxIters</i> . Default is 100 for <i>stepMethod</i> (<i>/M</i> flag) 0-2, 10000 for <i>stepMethod</i> = 3 (simulated annealing). If you use this form of the <i>/I</i> flag with simulated annealing, <i>maxItersAtT</i> is set to <i>maxIters</i> /2 and <i>maxAcceptances</i> is set to <i>maxIters</i> /10.
<i>/I</i> = <i>{maxIters, maxItersAtT, maxAcceptances}</i>	Specifies the number of iterations for simulated annealing. The maximum number of iterations is set by <i>maxIters</i> , <i>maxItersAtT</i> sets the maximum number of iterations at a given temperature in the cooling schedule, and <i>maxAcceptances</i> sets the total number of accepted changes in the X vector (whether they increase or decrease the function) at a given temperature. If you use this form of the flag with any <i>stepMethod</i> (<i>/M</i> flag) other than 3, <i>maxItersAtT</i> and <i>maxAcceptances</i> are ignored. Defaults for <i>stepMethod</i> = 3 are {10000, 5000, 500}.

/M={stepMethod, hessMethod}

Specifies the method used for selecting the next step (*stepMethod*) and the method for calculating the Hessian (matrix of second derivatives) with multivariate functions.

<i>stepMethod</i>	Method	<i>hessMethod</i>	Method
0	Line Search	0	secant (BFGS)
1	Dogleg	1	finite differences
2	More-Hebdon		
3	Simulated Annealing		

Default values are {0,0}. The *hessMethod* variable is ignored if you select *stepMethod* = 3.

/Q

Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.

/R={typX1, typX2, ...}

/R=typXWave

Specifies the expected size of X values with multivariate functions. These values are used to scale X values. If the X values you expect are very different from one, you will get more accurate results if you can give a reasonable estimate. Optimize will use *typXi* to scale X_i to reduce floating-point truncation error.

You must provide the same number of values in either a wave or a list of values as you provide to the */X* flag.

Ignored with simulated annealing (*/M={3,0}*).

/S=stepMax

Limits the largest scaled step size allowed with multivariate functions. Optimize will stop if five consecutive steps exceed *stepMax*.

Ignored with simulated annealing (*/M={3,0}*).

/SSA=stepWave

Name of a 3-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (*/M={3,0}*). *stepWave* sets information about the step size used to generate new X vectors. The step sizes are in terms of normalized X values. The normalization is such that the X_i ranges from -1 to 1 based on the ranges set by the */XSA* flag.

Column zero sets the step size used when creating new trial X vectors. Default is 1.0.

Column one sets the minimum step size. Default is 0.001.

Column two sets the maximum step size. Default is 1.0.

/T=tol

Sets the stopping criterion with univariate functions. Optimize will attempt to find a minimum within $\pm tol$.

When this form is used with a multivariate function, *gradTol* is set to *tol* and *stepTol* is set to $gradTol^2$.

Ignored with simulated annealing (*/M={3,0}*).

/T={gradtol, stepTol}

Sets the stopping criteria for multivariate functions. Iterations stop if a point is found with estimated scaled gradient less than *gradTol*, or if an iteration takes a scaled step shorter than *stepTol*. Default values are {8.53618x10⁻⁶, 7.28664x10⁻¹¹}. These values are (6.022x10⁻¹⁶)^{1/3} and (6.022x10⁻¹⁶)^{2/3} as suggested by Dennis and Schnabel. 6.022x10⁻¹⁶ is the smallest double precision floating point number that, when added to 1, is different from 1.

Ignored with simulated annealing (*/M={3,0}*).

/TSA={InitialTemp, CoolingRate}

Used only with simulated annealing (*/M={3,0}*).

InitialTemp sets the initial temperature. If *InitialTemp* is set to zero, Optimize calls your function 100 times to estimate the best initial temperature. This is the recommended setting unless your function is very expensive to evaluate (in which case, you may not want to use simulated annealing at all).

CoolingRate sets the factor by which the temperature is decreased.

/X=xWave

/X={x1, x2, ...}

Sets the starting point for searching for an extreme point with multivariate functions or with simulated annealing (*/M={3,0}*). The starting point can be specified with a wave

having as many points as the number of independent variables, or you can write out a list of X values in braces. If you are finding extreme points of a univariate function, use /L and /H instead unless you are using the simulated annealing method. If you specify a wave, this wave is also used to receive the result of the extreme point search.

/XSA=XLimitWave Name of a 2-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/M={3,0}).

Column zero sets the minimum value allowed for each element of the X vector.

Column one sets the maximum value allowed for each element of the X vector.

Default is $\pm X_i \cdot 10$ if X_i is nonzero, or ± 1 if X_i is zero. While a default is provided, it is highly recommended that you provide an XLimitWave.

/Y=funcSize Specifies expected sizes of function values with multivariate functions. If you expect your function will return values very different from one, you should set funcSize to the expected size. Optimize will use this value to scale the function results to reduce floating-point truncation error.

Parameters

func specifies the name of your user-defined function that will be optimized.

pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.

Function Format

Finding extreme points of a nonlinear function requires that you realize the function as a Igor user function of a certain form. See **Finding Minima and Maxima of Functions** on page III-281 for detailed examples.

Your function must look like this:

```
Function myFunc(w,x1, x2, ...)
    Wave w
    Variable x1, x2
    return f(x1, x2, ...)           // an expression ...
End
```

A univariate function would have only one X variable.

A multivariate function can use a wave to pass in the X values:

```
Function myFunc(w,xw)
    Wave w
    Wave xw
    return f(xw)                   // an expression ...
End
```

Replace “f(…)” with an appropriate numerical expression.

Univariate Details

The method used by Optimize to find extreme points of univariate functions requires that the point be bracketed before starting. If you don't use /L and /H to specify the bracketing X values, the defaults are zero and one. Optimize first attempts to find the requested extreme point using the bracketing values (or the default). If that is unsuccessful, it attempts to bracket an extreme point by expanding the bracketing interval. If a suitable interval is found (the search is by no means perfectly reliable), then the search for an extreme point is made again.

Optimize uses Brent's method for univariate functions, which requires no derivatives. This combines a quadratic extrapolation with checking for wild results. In the case of wild results (points beyond the best current bracketing values) the method reverts to a golden section bisection algorithm. For well-behaved functions, the quadratic extrapolation converges superlinearly. The golden section bisection algorithm converges more slowly but features global convergence, that is, if an extremum is there, it will be found.

The stopping criterion is $\left| \frac{x - (a + b)}{2} \right| + \frac{a - b}{2} \leq \frac{2}{3} \cdot tol$.

In this expression, a and b are the current bracketing values, and x is the best estimate of the extreme point within the bracketing interval.

The left side of this expression works out to being simply the distance from the current solution to the boundary of the bracketing interval.

Note: Optimizing a univariate function with the simulated annealing method (/M={3,0}) works like a multivariate function, and this section does not apply. See the sections devoted to simulated annealing.

Multivariate Details

With multivariate functions, Optimize scales certain quantities to reduce floating point truncation error. You enter scaling factors using the /R and /Y flags. The /R flag specifies the expected magnitude of X values; Optimize then uses $X_i/\text{typ}X_i$ in all calculations. Likewise, /Y specifies the expected magnitude of function values.

This scaling can be important for maintaining accuracy if your X's or Y's are very different from one, and especially if your X's have values spanning orders of magnitude.

The Optimize operation uses a quasi-Newton method with derivatives estimated numerically. The function gradient is calculated using finite differences. For estimation of the Hessian (second derivative matrix) you can use either a secant method (*hessMethod* = 0) or finite differences (*hessMethod* = 1). The finite difference method gives a more accurate estimate and may succeed with difficult functions but requires more function evaluations per iteration. The finite difference method's greater accuracy may reduce the total number of iterations required, so the overall number of function evaluations depends on details of the problem being solved. Usually the secant method requires fewer function evaluations and is preferred for functions that are expensive to evaluate.

Once a Newton step is calculated, there are three choices for the method used to find the best next value-line search along the Newton direction (*stepMethod* = 0), double dogleg (*stepMethod* = 1), or More-Hebdon (*stepMethod* = 2). The best method can be found only by experimentation. See Dennis and Schnabel (cited in **References**) for details.

The /F=*trustRegion*, /S=*stepMax* and /T={..., *stepTol*} all refer to scaled step sizes. That is,

$$\text{step}X_i = \left\{ \frac{|\Delta x_i|}{\max(x_i, \text{typ}X_i)} \right\}.$$

The Optimize operation presumes that an extreme point has been found when either the gradient at the latest point is less than *gradTol* or when the last step taken was smaller than *stepTol*. These criteria both refer to scaled quantities:

$$\max_{1 \leq i \leq n} \left\{ |g_i| \cdot \frac{\max(|x_i|, \text{typ}X_i)}{\max(|f|, \text{funcSize})} \right\} \leq \text{gradTol} \quad \text{or} \quad \max_{1 \leq i \leq n} \left\{ \frac{|\Delta x_i|}{\max(x_i, \text{typ}X_i)} \right\} \leq \text{stepTol}.$$

Simulated Annealing Introduction

The simulated annealing or Metropolis algorithm optimizes a function using a random search of the X vector space. It does not use derivatives to guide the search, making it a good choice if the function to be optimized is in some way poorly behaved. For instance, it is a good method for functions with discontinuities in the function value or in the derivatives.

Simulated annealing also has a good chance of finding a global minimum or maximum of a function having multiple local minima or maxima.

Because simulated annealing uses a random search method, it may require a large number of function evaluations to find a minimum, and it is not guaranteed that it will stop at an actual minimum. For these reasons, it is best to use one of the other methods unless those methods have failed.

The simulated annealing method generates new trial solutions by adding a random vector to the current X vector. The elements of the random vector are set to $\text{stepsize}_i \cdot R_i$, where R_i is a random number in the interval (-1, 1). As the solution progresses, the *stepsize* is gradually decreased.

Bad trials, that is, those that change the function value in the wrong direction are accepted with a probability that depends on the simulated temperature. It is this aspect that allows simulated annealing to find a global minimum.

Function values are generated and accepted or rejected for some number of iterations at a given temperature, then the temperature is reduced. The probability of a bad iteration being accepted decreases with decreasing temperature. A too-fast cooling rate can freeze in a bad solution.

Simulated Annealing Details

It is highly recommended that you use the XSA flag to specify *XLimitWave*. This wave sets bounds on the values of the elements of the X vector during the random search. The defaults may be adequate but are totally *ad hoc*. You are better off to specify bounds that make sense to the problem you are solving.

The values of *XLimitWave* in addition to bounding the search space also scale the X vector during computations of probabilities, temperatures, etc. Consequently, the X limits can affect the performance of the algorithm.

A large number of iterations is required to have a good probability of finding a reasonable solution.

It is recommended that you set the initial temperature to zero so that Optimize can estimate a good initial temperature. If you can't afford the 100 function evaluations required, you probably shouldn't be using simulated annealing.

Optimize uses an exponential cooling schedule in which $T_{i+1} = \text{CoolingRate} * T_i$ (see the /TSA flag). *CoolingRate* must be in the range 0 to 1. A fast cooling rate (small value of *CoolingRate*) can cause simulated quenching; that is, a bad solution can be frozen in. Very slow cooling will result in slow convergence.

When simulated annealing is selected, the optimization is treated as multivariate even if your function has only a single X input. That is, the output variables and waves are the ones listed under multivariate functions.

Variables and Waves for Output

The Optimize operation reports success or failure via the V_flag variable. A nonzero value is an error code.

Variables for a univariate function:

V_flag	0:	Search for an extreme point was successful.
	57:	User abort.
	785:	Function returned NaN.
	786:	Unable to find bracketing values for an extreme point.

If you searched for a minimum:

V_minloc	X value at the minimum.
V_min	Function value (Y) at the minimum.

If you searched for a maximum:

V_maxloc	X value at the maximum.
V_max	Function value (Y) at the maximum.

For simulated annealing only:

V_SANumIncreases	Number of "bad" iterations accepted.
V_SANumReductions	Number of iterations resulting in a better solution.

Variables for a multivariate function:

V_flag	0:	Search for an extreme point was successful.
	57:	User abort.
	788:	Iteration limit was exceeded.
	789:	Maximum step size was exceeded in five consecutive iterations.
	790:	The number of points in the typical X size wave specified by /R does not match the number of X values specified by the /X flag
	791:	Gradient nearly zero and no iterations taken. This means the starting point is very nearly a critical point. It could be a solution, or it could be so close to a saddle point or a maximum (when searching for a minimum) that the gradient has no useful information. Try a slightly different starting point.
V_OptTermCode	Indicates why Optimize stopped. This may be useful information even if V_flag is zero. Values are:	
	1:	Gradient tolerance was satisfied.
	2:	Step size tolerance was satisfied.
	3:	No step was found that was better than the last iteration. This could be because the current step is a solution, or your function may be too nonlinear for Optimize to

Override

solve, or your tolerances may be too large (or too small), or finite difference gradients are not sufficiently accurate for this problem.

- 4: Iteration limit was exceeded.
- 5: Maximum step size was exceeded in five consecutive iterations. This may mean that the maximum step size is too small, or that the function is unbounded in the search direction (that is, goes to -inf if you are searching for a minimum), or that the function approaches the solution asymptotically (function is bounded but doesn't have a well-defined extreme point).
- 6: Same as V_flag = 791.

If you searched for a minimum:

V_min Function value (Y) at the minimum.

If you searched for a maximum:

V_max Function value (Y) at the maximum.

Variables for all functions:

V_OptNumIters Number of iterations taken before Optimize terminated.

V_OptNumFunctionCalls Number of times your function was called before Optimize terminated.

Waves for a multivariate function:

W_extremum Solution if you didn't use /X=<xWave>. Otherwise the solution is returned in your X wave.

W_OptGradient Estimated gradient of your function at the solution.

See Also

Finding Minima and Maxima of Functions on page III-281 for further details and examples.

References

The Optimize operation uses Brent's method for univariate functions. *Numerical Recipes* has an excellent discussion (see section 10.2) of this method (but we didn't use their code):

Press, William H., Saul A. Teukolsky, William T. Vetterling, and Brian P. Flannery, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

For multivariate functions Optimize uses code based on Dennis and Schnabel. To truly understand what Optimize does, read their book:

Dennis, J. E., Jr., and Robert B. Schnabel, *Numerical Methods for Unconstrained Optimization and Nonlinear Methods*, 378 pp., Society for Industrial and Applied Mathematics, Philadelphia, 1996.

Override

Override constant *objectName* = newVal

Override strconstant *objectName* = newVal

Override Function *funcName*()

The Override keyword redefines a constant, strconstant, or user function. The *objectName* or *funcName* must be the same as the name of the original object or function that is being redefined. The override must be defined before the target object appears in the compile sequence.

See Also

Function Overrides on page IV-66 and **Constants** on page IV-38 for further details.

p

p

The p function returns the row number of the current row of the destination wave when used in a wave assignment statement. The row number is the same as the point number for a 1D wave.

Details

Outside of a wave assignment statement p acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also

Waveform Arithmetic and Assignments on page II-80.

For other dimensions, the **q**, **r**, and **s** functions.

For scaled dimension indices, the **x**, **y**, **z**, and **t** functions.

p2rect

p2rect (z)

The p2rect function returns a complex value in rectangular coordinates derived from the complex value *z* which is assumed to be in polar coordinates (magnitude is stored in the real part and the angle, in radians, in the imaginary part of *z*).

Examples

Assume waveIn and waveOut are complex, then:

```
waveOut = p2rect(waveIn)
```

sets each point of waveOut to the rectangular coordinates based on the magnitude in the real part and the angle (in radians) in the imaginary part of the points in waveIn.

You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

See Also

The functions **cmplx**, **conj**, **imag**, **r2polar**, and **real**.

PadString

PadString(str, finalLength, padValue)

The PadString function returns a string identical to *str* except that it has been extended to a total length of *finalLength* using bytes of *padValue*. Use zero to create a C-language style string or use 0x20 to pad with spaces (FORTRAN style). This is useful when reading or writing binary files using **FBinRead** and **FBinWrite**.

Panel

Panel

Panel is a procedure subtype keyword that identifies a macro as being a control panel recreation macro. It is automatically used when Igor creates a window recreation macro for a control panel. See **Procedure Subtypes** on page IV-149 and **Saving a Window as a Recreation Macro** on page II-51 for details.

ParamIsDefault

ParamIsDefault(pName)

The ParamIsDefault function determines if an optional user function parameter *pName* was specified during the function call. It returns 1 when *pName* is default (not specified) or it returns 0 when it was specified.

Details

ParamIsDefault works only in the body of a user function and only with optional parameters. The variable *pName* must be valid at compile time; you can not defer lookup to runtime with \$.

See Also

Optional Parameters on page IV-29 and **Using Optional Parameters** on page IV-46.

ParseFilePath

ParseFilePath(mode, pathInStr, separatorStr, whichEnd, whichElement)

The ParseFilePath function provides the ability to manipulate file paths and to extract sections of file paths.

Parameters

Several of the modes refer to elements of the file path. In these modes, *whichEnd* is 0 to select an element relative to the beginning of *pathInStr*, 1 to select an element relative to the end. *whichElement* is zero-based.

pathInStr is the input path, assumed to either a full path, a partial path (starts with the separator specified by *separatorStr*) or a simple file or folder name (contains no separators).

<i>mode</i>	Information Returned						
0	Element specified by <i>whichEnd</i> and <i>whichElement</i> .						
1	Entire <i>pathInStr</i> , up to but not including the element specified by <i>whichEnd</i> and <i>whichElement</i> .						
2	Entire <i>pathInStr</i> with a trailing separator added if it is not already there. This is useful when you have a path to a folder and want to tack on a file name.						
3	Last element of <i>pathInStr</i> with the extension, if any, removed. The extension is anything after the last dot in <i>pathInStr</i> .						
4	Extension in <i>pathInStr</i> or "" if there is no extension. The extension is anything after the last dot in <i>pathInStr</i> .						
5	Entire <i>pathInStr</i> but converts it to a format determined by <i>separatorStr</i> . <table border="0"> <tr> <td><i>separatorStr</i> = ":"</td><td>Converts the path to Macintosh style if it is Windows style. Does nothing to a Macintosh path.</td></tr> <tr> <td><i>separatorStr</i> = "\\ \"</td><td>Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path.</td></tr> <tr> <td><i>separatorStr</i> = "*"</td><td>Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path.</td></tr> </table>	<i>separatorStr</i> = ":"	Converts the path to Macintosh style if it is Windows style. Does nothing to a Macintosh path.	<i>separatorStr</i> = "\\ \"	Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path.	<i>separatorStr</i> = "*"	Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path.
<i>separatorStr</i> = ":"	Converts the path to Macintosh style if it is Windows style. Does nothing to a Macintosh path.						
<i>separatorStr</i> = "\\ \"	Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path.						
<i>separatorStr</i> = "*"	Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path.						
6	UNC volume name ("\\Server\Share") if <i>pathIn</i> is a UNC path or "" if it is not.						
7	UNC server name ("Server" from "\\Server\Share") if <i>pathIn</i> is a UNC path or "" if it is not.						
8	UNC share name ("Share" from "\\Server\Share") if <i>pathIn</i> is a UNC path or "" if it is not.						

separatorStr is ":" if *pathInStr* is a Macintosh path or "\\ \" if *pathInStr* is a Windows path. See **Path Separators** on page III-382 for details about Macintosh versus Windows paths.

whichEnd is 0 to extract an element from the beginning of *pathInStr* or 1 to extract if from the end. *whichEnd* is used only if *mode* is 0 or 1. For other modes, pass 0.

whichElement is a zero-based index to the element that you want to extract. *whichElement* is used only if *mode* is 0 or 1. For other modes, pass 0.

Details

When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See **Escape Characters in Strings** on page IV-13 and **Path Separators** on page III-382 for details.

On Windows two types of file paths are used: drive-letter paths and UNC ("Universal Naming Convention") paths. For example:

```
// This is a drive-letter path.
C:\Program Files\WaveMetrics\Igor Pro Folder\Igor.exe

// This is a UNC path.
\\BigServer\SharedApps\Igor Pro Folder\Igor.exe
```

In this example, ParseFilePath considers the volume name to be C: in the first case and \\BigServer\SharedApps in the second. The volume name is treated as one element by ParseFilePath, except for modes 7 and 8 which permit you to extract the components of the UNC volume name.

Except for the leading backslashes in a UNC path, ParseFilePath modes 0 and 1 internally strip any leading or trailing separator (as defined by the *separatorStr* parameter) from *pathInStr* before it starts parsing. So if you pass ":Igor Pro Folder:WaveMetrics Procedures:", it is the same as if you had passed "Igor Pro Folder:WaveMetrics Procedures".

If there is no element corresponding to *whichElement* and *mode* is 0, ParseFilePath returns "".

If there is no element corresponding to *whichElement* and *mode* is 1, ParseFilePath returns the entire *pathInStr*.

Examples

String pathIn, pathOut

```
// Full path
pathIn= "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"
// Extract first element.
Print ParseFilePath(0, pathIn, ":", 0, 0)          // Prints "hd"
// Extract second element.
Print ParseFilePath(0, pathIn, ":", 0, 1)          // Prints "Igor Pro Folder"
// Extract last element.
Print ParseFilePath(0, pathIn, ":", 1, 0)          // Prints "Wave Lists.ipf"
// Extract next to last element.
Print ParseFilePath(0, pathIn, ":", 1, 1)          // Prints "Waves"
// Get path to folder containing the file.
// Prints "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:"
Print ParseFilePath(1, pathIn, ":", 1, 0)
// Extract the file name without extension.
Print ParseFilePath(3, pathIn, ":", 0, 0)          // Prints "Wave Lists"
// Extract the extension.
Print ParseFilePath(4, pathIn, ":", 0, 0)          // Prints "ipf"
// Make sure the given path ends with a colon and concatenate file name.
String path = <routine that returns a Macintosh-style path to a folder>
path = ParseFilePath(2, path, ":", 0, 0)
path += "AFile.txt"
```

See Also

Escape Characters in Strings on page IV-13, **UNC Paths** on page III-383, and **Path Separators** on page III-382 for details. The **RemoveEnding** function.

ParseOperationTemplate

ParseOperationTemplate [*flags*] *cmdTemplate*

The ParseOperationTemplate operation helps XOP programmers and WaveMetrics programmers write code to implement Igor operations. If you are not an XOP programmer nor a WaveMetrics programmer, it will be of no interest.

ParseOperationTemplate is used to generate starter code for programmers who are creating Igor operations. The starter code is copied to the Clipboard, overwriting any previous Clipboard contents.

Flags

- /C=*c* If *c* is nonzero, ParseOperationTemplate stores code for your ExecuteOperation and RegisterOperation functions in the Clipboard.
Use /C=1 for simple code generation. Use /C=2 for more extensive code generation.
- /S=*s* Stores a definition of your runtime parameter structure in the Clipboard if *s* is nonzero.
This parameter affects code generation if you use mnemonic names in your template. With /S=1, your structure field names will be the same as the specified mnemonic names. This is fine if your mnemonic names are unique. However, if two or more of your parameters use the same mnemonic name, use /S=2. In this case, ParseOperationTemplate will create unique field names by concatenating flag or keyword text and the specified mnemonic names.
- /T Stores a comment listing your command template in the Clipboard.
- /TS Identifies a ThreadSafe operation by adding an extra field to the runtime parameter structure. This is only of use to WaveMetrics programmers.

Parameters

cmdTemplate is the template that describes the syntax for your operation. See the *Igor XOP Toolkit Reference Manual* for details.

Details

ParseOperationTemplate parses your command template, generating structures that embody the syntax of your operation. If the /C, /S or /T flags is used, it then uses these structures to generate code that can serve as a starting point for implementing your operation. The starter code is stored in the Clipboard.

For most uses, the recommended flags are /T/S=1/C=2.

ParseOperationTemplate sets the following output variable, but only when called from a function or macro:

v_flag 0: *cmdTemplate* was successfully parsed.

PathInfo

-1: *cmdTemplate* was not successfully parsed.

If *V_flag* is nonzero, this indicates that your *cmdTemplate* syntax is incorrect. See the *Igor XOP Toolkit Reference Manual* for details.

Examples

```
Function Test()  
    String cmdTemplate  
    cmdTemplate="MyTest /A={number,string} /B=wave key1={name[,wave,name,string[2]]}"  
    TestOperationParser/T/S=1/C=2 cmdTemplate  
    Print V_flag, S_value  
End
```

See Also

Igor Extensions on page III-407.

PathInfo

PathInfo [/S] *pathName*

The PathInfo operation stores information about the named symbolic path in the following variables:

V_flag: 0 if path does not exist, 1 if it does exist.

S_path: The full path (e.g., "hd:This:That:").

The path returned is a colon-separated path which can be used on Macintosh or Windows. See **Path Separators** on page III-382 for details.

Flags

/S Presets the next otherwise undirected open or save file dialog to the given disk folder.

Examples

The following lines perform equivalent actions:

```
PathInfo/S myPath;Open refNum  
Open/P=myPath refNum
```

PathList

PathList(*matchStr*, *separatorStr*, *optionsStr*)

The PathList function returns a string containing a list of symbolic paths selected based on the *matchStr* parameter.

Details

For a path name to appear in the output string, it must match *matchStr*. The first character of *separatorStr* is appended to each path name as the output string is generated.

PathList works like the WaveList function, except that the *optionsStr* parameter is reserved for future use. Pass "" for it.

Examples

When a new experiment is created there is only one path:

```
Print PathList("*",";","")
```

Prints the following in the history area:

```
Igor;
```

See Also

The **WaveList** function for an explanation of the *matchStr* and *separatorStr* parameters and for examples. See also **Symbolic Paths** on page II-30 for an explanation of symbolic paths.

PauseForUser

PauseForUser *mainWindowName* [, *targetWindowName*]

The PauseForUser operation pauses procedure execution until the specified window, *mainWindowName*, is killed. Until then, only mouse and keyboard activity directed toward either *mainWindowName* or *targetWindowName* will be allowed. This affects graph, table, and panel windows only.

While waiting for user action, `PauseForUser` disables double-clicks and any contextual menus that can lead to dialogs to prevent changes on the command line. It also disables killing windows by clicking the close icon in the title bar unless the window was originally created with the `/K=1` flag.

See Also

`Pause For User` on page IV-108 for examples and further discussion.

PauseUpdate

PauseUpdate

The `PauseUpdate` operation delays the updating of graphs and tables until you invoke a corresponding `ResumeUpdate` command.

Details

`PauseUpdate` is useful in a macro that changes a number of things relating to the appearance of a graph. It prevents the graph from being updated after each change. Its effect ends when the macro in which it occurs ends. It also affects updating of tables.

This operation is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the `DoUpdate` operation.

See Also

The `DelayUpdate`, `DoUpdate`, `ResumeUpdate`, and `Silent` operations.

PCA

PCA [*flags*][*wave0*, *wave1*,... *wave99*]

The PCA operation performs principal component analysis. Input data can be in the form of a list of 1D waves, a single 2D wave, or a string containing a list of 1D waves. The operation can produce multiple output waves depending on the specified flags.

Flags

<code>/ALL</code>	Shortcut for the combination of commonly used flags: <code>/CVAR</code> , <code>/SL</code> , <code>/NF</code> , <code>/IND</code> , <code>/IE</code> , and <code>/RMS</code> .
<code>/COV</code>	Calculates the input wave(s) covariance matrix, which as the input for the remainder of the analysis. The covariance matrix is computed by first creating a matrix copying each input 1D wave into sequential columns and then multiplying that matrix by its transpose.
<code>/CVAR</code>	Computes the cumulative percent variance defined as $100 * \text{sum of first } m \text{ eigen values} / \text{sum of all eigen values}$. The results are stored in the wave <code>W_CumulativeVAR</code> in the current data folder. See also <code>/VAR</code> .
<code>/IE</code>	Computes the imbedded error. Returns errors in the wave <code>W_IE</code> in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_IE</code> . The imbedded error is a function of the number of factors, the number of rows and columns and the sum of the eigen vectors not included in the significant factors. The behavior of <code>IE</code> determines the number of significant factors.
<code>/IND</code>	Computes the factor indicator function. Note that if you specify <code>/IND</code> the residual standard deviation will also be calculated. Returns results in the wave <code>W_IND</code> in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_IND</code> .
<code>/LEIV</code>	Limits eigen values so that the SVD calculation does not require too much memory. The limit is set to the minimum of the number of rows or columns of the input.
<code>/NF</code>	Finds the number of significant factors and stores it in the variable <code>V_npnts</code> . You must use <code>/IND</code> in order to compute the significant factors.
<code>/O</code>	Overwrites input waves.
<code>/Q</code>	Suppresses printing of factors in the history area.
<code>/RSD[=<i>rsdMode</i>]</code>	Computes the Residual Standard Deviation (RSD) and returns the RSD in the wave <code>W_RSD</code> in the current data folder. The first element in <code>W_RSD</code> is NaN and all remaining wave elements correspond to the number of significant factors. <i>rsdMode</i> =0: Covariance about the origin. <i>rsdMode</i> =1: Correlation about the origin.

/RMS	Computes the RMS error. Returns results in the wave W_RMS in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_RMS</code> .
/SCMT	Saves C matrix after the singular value decomposition (SVD) in the wave M_C in the current data folder.
/SCR	Converts the individual wave input into standard scores. Does not work when the input is a single 2D wave. It is an error to convert to standard scores when one or more entries in the waves are NaN or INF. If you use this feature make sure to use the appropriate form of the RSD calculation.
/SDM	Saves a copy of the data matrix at the end of the calculation. This is useful if your input consists of individual waves or if you want to save the computed standard scores. If the input is a 2D matrix, you will get a copy of the input matrix in the wave M_D.
/SEVC	Saves the eigen value vector in the wave W_Eigen, which are the raw eigen values generated by the SVD, in the current data folder. Normally, if the SVD was applied to a raw data matrix, i.e., not covariance or correlation matrix, you must square each element of the wave to obtain the PCA eigen values. Note that this wave has default wave scaling.
/SL	Computes percent significance level and stores it in the wave W_PSL in the current data folder.
/SQEV	Does not square SVD eigen values. If you specify /COV there is no need to use this flag. Use only if your input is already a covariance matrix. In this case the results of the SVD are the eigen values not their square roots.
/SRMT	Saves R matrix after the SVD in the wave M_R in the current data folder.
/U	Leaves the input waves unchanged only when the input is a 2D wave. Note that covariance calculations will not be made even if the appropriate flag is used.
/VAR	Computes the variance associated with each eigen value. The variance is defined as the ratio of the eigen value to the sum of all eigen values. The results are stored in the wave W_VAR in the current data folder. See also /CVAR above.
/WSTR= <i>waveListStr</i>	String containing a list of names for all input waves.
/Z	No error reporting.

Details

The input is either via /WSTR=*waveListStr* or a list of up to 100 1D waves or a single 2D wave following the last flag.

waveListStr is string containing a semicolon-separated list of 1D waves to be used for the data matrix. *waveListStr* can include any legal path to a wave. Liberal names can be quoted or not quoted. It is assumed that all waves are of the same numerical type (either single or double precision) and that all waves have the same number of points.

Regardless of the inputs, the operation expects that the number of rows in the resulting matrix is greater than or equal to the number of columns.

The operation starts by creating the data matrix from the input wave(s). If you provide a list of 1D waves they become the columns of the data matrix. You can choose to use the covariance matrix (/COV) as the data matrix and you can also choose to normalize each column of the data matrix to convert it into standard scores. This involves computing the average and standard deviation of each column and then setting the new values to be:

$$newValue = \frac{oldValue - colAverage}{colStdv}.$$

You can pre-process the input data using **MatrixOP** with the SubtractMean, NormalizeRows, and NormalizeCols functions.

After creating the data matrix the operation computes the singular value decomposition (SVD) of the data matrix. Results of the SVD can be saved or processed further. Save the C and R matrices using /SCMT and /SRMT. These are related to the input data matrix through: $D = R \cdot C$.

The remainder of the operation lets you compute various statistical quantities defined by Malinowski (see References). Use the flags to determine which ones are computed.

The operation generates a number of output waves. All waves are stored in the current data folder.

You can save the input matrix D in the wave M_D, the optional SVD results are stored in the waves M_C that contains the column matrix C, M_R that contains the row matrix R, and W_Eigen that contains the eigen values of the data matrix. Note that these can be the eigen values or the square of the eigen values depending on the input matrix being a covariance matrix or not (see /SQEV).

The optional 1D output waves (W_RSD, W_RMS, W_IE, W_IND, W_PSL) are saved with wave scaling to make it easier to display the wave as a function of the number of factors.

pcsr

pcsr(cursorName [, graphNameStr])

The pcsr function returns the point number of the point which the specified cursor (A through J) is on in the top (or named) graph. When used with cursors on images or waterfall plots, pcsr returns the row number, and when used with a free cursor, it returns the relative X coordinate.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The pcsr result is not affected by any X axis.

See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **qcsr**, **vcscr**, **xcscr**, and **zcscr** functions.

Pi

Pi

The Pi function returns π (3.141592...).

PICTInfo

PICTInfo(pictNameStr)

The PICTInfo function returns a string containing a semicolon-separated list of information about the named picture. If the named picture does not exist, then "" is returned. Valid picture names can be found in the Pictures dialog.

Details

The string contains six pieces of information, each prefaced by a keyword and colon and terminated with a semicolon.

Keyword	Information Following Keyword
TYPE	One of: "PICT", "PNG", "JPEG", "Enhanced metafile", "Windows metafile", "DIB", "Windows bitmap", or "Unknown type".
BYTES	Amount of memory used by the picture.
WIDTH	Width of the picture in pixels.
HEIGHT	Height of the picture in pixels.
PHYSWIDTH	Physical width of the picture in points.
PHYSHEIGHT	Physical height of the picture in points.

Examples

```
print PictInfo("PICT_0")
```

will print the following in the history area:

```
TYPE:PICT;BYTES:55734;WIDTH:468;HEIGHT:340;PHYSWIDTH:468;PHYSHEIGHT:340;
```

See Also

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTList** function. The **StringFromList** operation for parsing the information string.

See **Pictures** on page III-405 and **Pictures Dialog** on page III-406 for general information on picture handling.

PICTList

PICTList(*matchStr*, *separatorStr*, *optionsStr*)

The **PICTList** function returns a string containing a list of pictures based on *matchStr* and *optionsStr* parameters. See **Details** for information on listing pictures in graphs, panels, layouts, and the picture gallery.

Details

For a picture name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr*. The first character of *separatorStr* is appended to each picture name as the output string is generated.

The name of each picture is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches all picture names.
"xyz"	Matches picture name xyz only.
"*xyz"	Matches picture names which end with xyz.
"xyz*"	Matches picture names which begin with xyz.
"*xyz*"	Matches picture names which contain xyz.
"abc*xyz"	Matches picture names which begin with abc and end with xyz.

matchStr may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

"!*xyz"	Matches picture names which do not end with xyz.
---------	--

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

optionsStr is used to further qualify the picture.

Use " " accept all pictures in the Pictures Dialog that are permitted by *matchStr*.

Use the WIN: keyword to limit the pictures to the named or target window:

"WIN:"	Match all pictures displayed in the top graph, panel, or layout.
"WIN:windowName"	Match all pictures displayed in the named graph, panel, or layout window.

Examples

PICTList ("*", ";", "")	Returns a list of all pictures in the Pictures Dialog.
PICTList ("*", ";", "WIN:")	Returns a list of all pictures displayed in the top panel, graph, or layout.
PICTList ("*_bkg", ";", "WIN:Layout0")	Returns a list of pictures whose names end in "_bkg" and which are displayed in Layout0.

See Also

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTInfo** function. Also the **StringFromList** function for retrieving items from lists.

See **Pictures** on page III-405 and **Pictures Dialog** on page III-406 for general information on picture handling.

Picture

Picture *pictureName*

The Picture keyword introduces an ASCII code picture definition of binary image data.

See Also

Proc Pictures on page IV-44 for further information.

PixelFromAxisVal

PixelFromAxisVal(*graphNameStr*, *axNameStr*, *val*)

The PixelFromAxisVal function returns the local graph pixel coordinate corresponding to the axis value in the graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is "left" or "bottom" then the first vertical or horizontal axis will be used.

See Also

The **AxisValFromPixel** and **TraceFromPixel** functions.

PlayMovie

PlayMovie [*flags*] [*as fileNameStr*]

The PlayMovie operation opens a QuickTime movie file into a window and plays it.

Parameters

The file to be opened is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/I	Coordinates are in inches.
/M	Coordinates are in centimeters.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/W=(<i>left,top,right,bottom</i>)	Sets the initial coordinates of the movie window (in points unless /I or /M are used before /W).
/Z	No error reporting; an error is indicated by nonzero value of the variable V_flag. If the user clicks the cancel button in the Open File dialog, V_flag is set to -1.

Details

Coordinates are the initial coordinates of the movie window in points unless /I or /M are used before /W. Only the *top* and *left* coordinates are used. The window has the standard width and height for movies.

If either the path or *fileNameStr* is omitted then PlayMovie will bring up a dialog to let you find a movie file. If both are present, PlayMovie opens the file automatically.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

Any movie file can be played, not just movies made by Igor. There is no limit on the number of movie windows opened for playing.

Movie windows are considered transient and are not restored when an experiment is reopened.

PlayMovieAction

See Also

The **PlayMovieAction** operation.

PlayMovieAction

PlayMovieAction [**/Z**] **keyword** [=value][, **keyword** [=value]]

PlayMovieAction operates on the top movie window (opened via **PlayMovie**).

If the /Z flag is present, errors are not fatal. V_flag is set to error return regardless.

Parameters

extract	Extracts current frame into an 8-bit RGB image wave named M_MovieFrame. (Can be combined with frame=f.)
extract=e	Extracts <i>e</i> frames into a single multiframe wave, M_MovieChunk. This wave will have 3 planes for RGB and will have <i>e</i> chunks.
frame=f	Moves to specified movie frame (and stops movie).
getID	Returns top movie ID number in V_Value. Do not use in same call with getTime.
getTime	Reads current movie time into variable V_value (in seconds).
gotoBeginning	Goes to beginning of movie.
gotoEnd	Goes to end of movie.
kill	Kills movie window.
setFrontMovie=id	Sets movie with given <i>id</i> as top window. Error if no such window (use /Z to suppress errors). Do not use in same call with getID.
start	Starts movie playing.
step=s	Moves by <i>s</i> frames into movie (0 is same as 1, negative values move backwards).
stop	Stops movie.

Flags

/Z No error reporting; an error is indicated by nonzero value of the variable V_flag.

Details

Operations are performed in the following order: kill, stop, gotoBeginning, gotoEnd, frame, step, getTime, extract, start. kill overrides all other parameters.

If you want to extract a grayscale image, you can convert the RGB image into grayscale using the ImageTransform command as follows:

```
PlayMovieAction extract
ImageTransform rgb2gray M_MovieFrame
NewImage M_RGB2Gray
```

Examples

How to determine the number of frames in a simple movie:

```
PlayMovie
PlayMovieAction stop, gotoEnd, getTime
Variable tend= V_value
PlayMovieAction step=-1, getTime
Print "frames= ", tend/(tend-V_value)
PlayMovieAction kill
```

See Also

The **PlayMovie** operation.

PlaySnd

PlaySnd [**flags**] **fileNameStr**

Available only on the Macintosh.

The PlaySnd operation plays a sound from the file's data fork, or from an 'snd' resource.

Parameters

The file containing the sound is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path

relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/I= <i>resourceIndex</i>	Specifies the 'snd ' resource to load by resource index, starting from 1.
/M= <i>promptStr</i>	Specifies a prompt if PlaySnd needs to put up a dialog to find the file.
/N= <i>resNameStr</i>	Specifies the resource to load by resource name.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/Q	Quiet: suppresses the insertion of 'snd ' info into the history area.
/R= <i>resourceID</i>	Specifies the 'snd ' resource to load by resource ID.
/Z	Does not play the sound, just checks for its existence.

Details

If none of /I, /N or /R are specified, PlaySnd tries to play a sound stored in the data fork of the file. If the file dialog is used, only files of type 'sfil' are shown.

If any of /I, /N or /R are specified, PlaySnd tries to play a sound from an 'snd ' resource. Most programs store sounds in 'snd ' resources. If the file dialog is used, files of all types are shown.

If /P=*pathName* is omitted, then *fileNameStr* can take on three special values:

"Clipboard"	Loads data from Clipboard.
"System"	Loads data from System file.
"Igor" (not "Igor Pro")	Loads data from Igor Pro application.

If you specify /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

There are no sounds in the Igor Pro application file.

If the file is not fully specified and *fileNameStr* is not one of these special values, then PlaySnd presents a dialog from which you can select a file. "Fully specified" means that Igor can determine the name of the file (from the *fileNameStr* parameter) and the folder containing the file (from the /P=*pathName* flag or from the *fileNameStr* parameter).

PlaySnd sets the variable V_flag to 1 if the sound exists and fits in available memory or to 0 otherwise.

If the sound exists, PlaySnd also sets the string variable S_Info to:

```
"SOURCE:sourceName;RESOURCENAME:resourceName;RESOURCEID:resourceID"
```

If the sound is not a resource then *resourceName* is "" and *resourceID* is 0. *sourceName* will be the name of the file that was loaded or "Clipboard", "System" or "Igor".

Examples

```
PlaySnd/I=1/P=mySnds/Z "Wild Eep"
If (V_flag)           // Any 'snd ' in the "Wild Eep" file?
    Print S_info      // Yes, print resource number, etc.
Endif
```

This prints the following into the history area:

```
SOURCE:resource fork;RESOURCENAME:Wild Eep;RESOURCEID:8;
```

PlaySound

PlaySound [/A[=*a*] /C] *soundWaveName*

PlaySound /A[=*a*] {*soundWaveName1*, *soundWaveName2* [, *soundWaveNameN*...]}

The PlaySound operation plays the audio samples in the named wave. The various sound output parameters — number of samples, sample rate, number of channels, and number of bits of resolution — are determined by the corresponding parameters of the wave.

Flags

/A[=a] Plays sounds asynchronously so that sounds will continue to play after the command itself has executed.

- /A=0:** Same as no /A flag.
- /A=1:** Plays sounds asynchronously; same as /A.
- /A=2:** Stop playing any current sound before starting this one
- /A=3:** Return with user abort error if output buffers are full (rather than waiting.) Use `GetRTErr(1)` to detect and clear the error condition.

/C Samples audio at 16 bits. Has no effect with 8-bit waves.

Details

The wave's time per point, as determined by its X scaling, which must be between 2×10^{-4} and 1.5625×10^{-5} or sampling rates of 5000 to 64000 Hertz.

For waves that are 8-bit integers or 32-bit floats, the audio samples will be converted to 8 bits and should range between -128 and +127.

If the wave is 16-bit integers or if the /C (for CD) flag is used, the samples will be converted to 16 bits and should range between -32768 and +32767. If an 8-bit wave is used then the /C flag is ignored.

With the /A flag, the sound plays asynchronously (i.e., the command returns before the sound is finished). If another command is issued before the sound is finished then the new command will wait until the last sound finishes. A PlaySound without the /A flag can play on top of the current sound. The transition between sounds should be seamless on Macintosh but may be slightly delayed on Windows.

It is OK to kill a sound wave immediately after PlaySound returns even if the /A flag is used.

To play a stereo sound, provide a 2 column wave with the left channel in column 0. Actually, the software will attempt to play as many channels as there are columns in the wave. You can also use multiple 1D waves with the /A flag. To use this method, enclose the list of 1D waves in braces

Note: The SoundInput operations provide matching sound recording capabilities. See the **SoundInStatus** operation.

Examples

Under Windows, support for sound is somewhat idiosyncratic so these sound examples may not work correctly with your particular hardware configuration.

```
Make/B/O/N=1000 sineSound // 8 bit samples
SetScale/P x,0,1e-4,sineSound // Set sample rate to 10Khz
sineSound= 100*sin(2*Pi*1000*x) // Create 1Khz sinewave tone
PlaySound sineSound
```

The following example will create a rising pitch in the left channel and a falling pitch in the right channel:

```
Make/W/O/N=(20000,2) stereoSineSound // 16 bit data
SetScale/P x,0,1e-4, stereoSineSound // Set sample rate to 10Khz
stereoSineSound= 20000*sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
PlaySound/A stereoSineSound // 16 bit, asynchronous
```

Multichannel sounds as in the previous example but from multiple 1D waves:

```
Make/W/O/N=20000 stereoSineSoundL, stereoSineSoundR // 16 bit data
SetScale/P x,0,1e-4, stereoSineSoundL, stereoSineSoundR // Set sample rate to 10Khz
stereoSineSoundL= 20000*sin(2*Pi*(1000 + 150*x)*x) // rising pitch in left
stereoSineSoundR= 20000*sin(2*Pi*(1000 - 150*x)*x) // falling in right
PlaySound/A {stereoSineSoundL, stereoSineSoundR} // two 1D waves
```

pnt2x**pnt2x(waveName, pointNum)**

The pnt2x function returns the X value of the named wave at the point *pointNum*. The point number is truncated to an integer before use.

Details

The result is derived from the wave's X scaling, not any X axis of a graph it may be displayed in. If you would like to convert a fractional point number to an X value you can use:

`leftx(waveName)+deltax(waveName)*pointNum.`

There is no equivalent function for multidimensional waves. To calculate this information for other dimensions, use this expression:

`DimOffset(waveName, dim) + ScaledDimPos*DimDelta(waveName, dim)`

This expression calculates the scaled position of an element in the dimension *dim* (x, y, z, or t). *ScaledDimPos* is the element number in that dimension (p, q, r, or s). *dim* is 0 for rows, 1 for columns, 2 for layers or 3 for chunks. Setting *dim* = 0 is equivalent to using `pnt2x`. You may want to use **round**, **ceil**, or **floor** to truncate the result to an integer.

See Also

The functions **DimDelta** and **DimOffset**.

Waveform Model of Data on page II-64 and **Changing Dimension and Data Scaling** on page II-70 for an explanation of waves and dimension scaling.

poissonNoise

poissonNoise(num)

The `poissonNoise` function returns a pseudo-random value from the Poisson distribution whose probability distribution function is

$$f(x, \lambda) = \frac{e^{-\lambda} \lambda^x}{x!}, \quad \lambda > 0, \quad x = 0, 1, 2, \dots \quad \text{with mean and variance equal to } num1 (= \lambda).$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **SetRandomSeed**.

poly

poly(coefsWaveName, x1)

The `poly` function returns the value of a polynomial function at $x = x1$.

coefsWaveName is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial.

Examples

To fill `wave0` with 100 points containing the polynomial $1 + 2x + 3x^2 + 4x^3$ evaluated over the range from $x = -1$ to $x = 1$ (and graph it):

```
Make coefs = {1, 2, 3, 4} // f(x) = 1 + 2*x + 3*x^2 + 4*x^3
Make/N=100/O wave0; SetScale/I x, -1, 1, wave0; Display wave0
wave0 = poly(coefs, x)
```

poly2D

poly2D(coefsWaveName, x1, y1)

The `poly2D` function returns the value of a 2D polynomial function at $x = x1$, $y = y1$.

coefsWaveName is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial and therefore the polynomial degree.

Details

The coefficients wave contains polynomial coefficients for low degree terms first. All coefficients for terms of a given degree must be present, even if they are zero. Among coefficients for a given degree, those for terms having higher powers of X are first. Thus, `poly2D` returns, for a coefficient wave *cw*:

$$f(x, y) = cw[0] + cw[1]*x + cw[2]*y + cw[3]*x^2 + cw[4]*x*y + cw[5]*y^2 + \dots$$

A 2D polynomial of degree N has $(N+1)(N+2)/2$ terms.

Examples

To fill `wave0` with 400 points (20 by 20) containing the polynomial $1 + 2x + 2.5y + 3x^2 + 3.5xy + 4y^2$ evaluated over the range $x = (-1, 1)$ and $y = (-1, 1)$ and make a contour plot of it:

PolygonArea

```
Make/O coefs = {1, 2, 2.5, 3, 3.5, 4}
Make/N=(20,20)/O wave0
SetScale/I x, -1, 1, wave0
SetScale/I y, -1, 1, wave0
wave0 = poly2D(coefs, x, y)
Display; AppendMatrixContour wave0
```

The polynomial is second degree, so the first command above made the wave coefs with six elements because $(2+1)(2+2)/2 = 6$.

To fill wave0 with 100 points containing the polynomial $1 + 2x + 3y + 4x^2 + 4y^2 + 5x^3 + 6y^3$ (note the lack of cross terms) evaluated over the range $x = (-1, 1)$ and $y = (-1, 1)$ (the contour plot already made should update with the new data). The first zero eliminates the second-order cross term $x*y$ and the second and third zeros eliminate the third-order cross terms x^2*y and $x*y^2$:

```
Make/O coefs = {1, 2, 3, 4, 0, 4, 5, 0, 0, 6}
wave0 = poly2D(coefs, x, y)
```

PolygonArea

PolygonArea(xWave, yWave)

The PolygonArea function returns the area of a simple, closed, convex or nonconvex planar polygon described by consecutive vertices in *xWave* and *yWave*.

A simple polygon has no internal “holes” and its boundary curve does not intersect itself. Both *xWave* and *yWave* must be 1D, real, numerical waves of the same dimensions. The minimum number of vertices is 3. The function uses the shoelace algorithm to compute the area (see theorem 1.3.3 in the reference below). If there is any error in the input, the function returns NaN.

Example

```
Function estimatePi(num)
    Variable num
    Make/O/N=(num+1) xxx,yyy
    xxx=sin(2*pi*x/num)
    yyy=cos(2*pi*x/num)
    printf "Relative Error=%g\r", (pi-PolygonArea(xxx,yyy))/pi
End
```

See also

The **areaXY** and **faverageXY** functions.

O'Rourke, Joseph, *Computational Geometry in C*, 2nd ed., Cambridge University Press, New York, 1998.

popup

popup menuList

The popup keyword is used with Prompt statements in Functions and Macros. It indicates that you want a pop-up menu instead of the normal text entry item in a DoPrompt simple input dialog (or a Macro's missing parameter dialog (archaic)). *menuList* is a string expression containing a list of items, separated by semicolons, that are to appear in the pop-up menu.

Pop-up menus accept both numeric and string parameters. For numeric parameters, the number of the item selected is placed in the variable. Numbering starts from one. For string parameters, the selected item's text is placed in the string variable.

Pop-up items support all of the special characters available for user-defined menu definitions (see **Special Characters in Menu Item Strings** on page IV-96) with the exception that items in pop-up menus are limited to 50 characters, keyboard shortcuts are not supported, and special characters must be enabled.

See Also

Prompt, **DoPrompt**, and **Pop-Up Menus in Simple Dialogs** on page IV-105.

See **WaveList**, **TraceNameList**, **ContourNameList**, **ImageNameList**, **FontList**, **MacroList**, **FunctionList**, **StringList**, and **VariableList** for functions useful in generating lists of Igor objects.

Chapter III-14, **Controls and Control Panels** for details about control panels and controls.

PopupContextualMenu

PopupContextualMenu [**/C=(xpix, ypix)**] **popupStr**

The PopupContextualMenu operation displays a popup menu until the user makes a selection or cancels the menu by clicking outside of its window.

The menu appears at the current mouse position or at the location specified by the /C flag.

Parameters

popupStr specifies the pop-up menu's items. *popupStr* is a semicolon-separated list of items such as "yes;no;maybe;", or a string expression that returns such a list, such as **TraceNameList**.

The menu items can be formatted and checkmarked, like user-defined menus can. See **Special Characters in Menu Item Strings** on page IV-96.

Flags

/C=(xpix, ypix) Sets the coordinates of the menu's top left corner. Units are in pixels relative to the top-most window, such as the MOUSEX and MOUSEY values passed to a window hook. See the window hook example, below and **SetWindow**.
If /C is not specified, the menu's top left corner appears at the current mouse position.

Details

PopupContextualMenu sets the following variables:

V_flag	-1: User cancelled the menu without choosing an item, or there was an error such as an empty <i>popupStr</i> . 0: Error, such as an empty <i>popupStr</i> . ≥1: 1 if the first menu item was chosen, 2 for the second, etc.
S_selection	" " if the user cancelled or error, else the text of the selected menu item.

Examples

Formatting a menu item:

```
String checked= "\\M0:!" + num2char(18) + ":"          // checkmark code
String items= "first;\M1-;" + checked + "third;"      // 2nd is divider, 3rd is checked
PopupContextualMenu items
switch( V_Flag )
  case 1:
    // do something because first item was chosen
    break;
  case 3:
    // do something because first item was chosen
    break;
endswitch
```

Window hook example:

```
SetWindow kwTopWin hook=TableHook, hookevents=1      // mouse down events
Function TableHook(infoStr)
  String infoStr
  Variable handledEvent=0
  String event= StringByKey("EVENT",infoStr)
  strswitch(event)
    case "mousedown":
      Variable isContextualMenu= NumberByKey("MODIFIERS",infoStr) & 0x10
      if( isContextualMenu )
        Variable xpix= NumberByKey("MOUSEX",infoStr)
        Variable ypix= NumberByKey("MOUSEY",infoStr)
        PopupContextualMenu/C=(xpix,ypix) "yes;no;maybe;"
        strswitch(S_selection)
          case "yes":
            // do something because "yes" was chosen
            break
          case "no":
            break
          case "maybe":
            // do something because "maybe" was chosen
            break
        endswitch
      handledEvent=1
```

```
        endif
    endswitch
    return handledEvent
End
```

See Also

Special Characters in Menu Item Strings on page IV-96 and Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

The **SetWindow** and **PopupMenu** operations.

PopupMenu

PopupMenu [/Z] *ctrlName* [*key* [= *value*]] [, *key* [= *value*]]...

The PopupMenu operation creates or modifies a pop-up menu control in the target or named window.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the PopupMenu control to be created or changed.

key is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of **default**, **native**, or **os9**.

platform can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

bodyWidth=*width*

Specifies an explicit size for the body (nontitle) portion of a PopupMenu control. By default (bodyWidth=0), the body portion autosizes depending on the current text. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

disable=*d*

Sets user editability of the control.

d=0: Normal.

d=1: Hide.

d=2: Draw in gray state; disable control action.

font="*fontName*"

Sets the font used for the pop-up title, e.g., font="Helvetica".

fsize=*s*

Sets the font size for the pop-up title.

fstyle=*fs*

fs is a binary coded number with each bit controlling one aspect of the font style as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

help={*helpStr*}

Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.

mode=*m*

Specifies the Pop-up title location.

m=0: Title is in pop-up menu.

m>0: Title is to the left of pop-up menu, the chosen menu item appears in the pop-up menu, and menu item number *m* is initially selected.

noproc

Specifies that no procedure is to execute when choosing in the pop-up menu.

<code>popColor=(<i>r,g,b</i>)</code>	Specifies the color initially chosen in the color pop-up palette. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. See the Colors, Color Tables, Line Styles, Markers, and Patterns section.
<code>popvalue=<i>valueStr</i></code>	Sets the string displayed by the menu when first created, if mode is not zero. See Popvalue Keyword section.
<code>pos={<i>left,top</i>}</code>	Sets position of pop-up menu in pixels.
<code>proc=<i>procName</i></code>	Specifies the procedure to execute when the pop-up menu is clicked.
<code>rename=<i>newName</i></code>	Gives pop-up menu a new name.
<code>size={<i>width,height</i>}</code>	Sets pop-up menu size in pixels.
<code>title=<i>titleStr</i></code>	Sets title of pop-up menu to the specified string expression. The title is the text that identifies the purpose of the pop-up menu.
<code>userdata(<i>UDName</i>)=<i>UDStr</i></code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional (<i>UDName</i>) to specify a named user data to create.
<code>userdata(<i>UDName</i>)+=<i>UDStr</i></code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional (<i>UDName</i>) to append to the named <i>UDStr</i> .
<code>value=<i>popupStr</i></code>	Specifies the pop-up menu's items. <i>popupStr</i> is a semicolon-separated list of items such as " yes ; no ; maybe ", or an expression that returns such a list, such as TraceNameList . You can also create pop-up controls containing colors and line styles; see the Colors, Color Tables, Line Styles, Markers, and Patterns section.
<code>win=<i>winName</i></code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window, or the window named with the `win=winName` keyword, must be a graph or panel.

The action procedure, which may be a function or a macro, has the format:

```
Function procName(ctrlName,popNum,popStr) : PopupMenuControl
    String ctrlName
    Variable popNum          // which item is currently selected (1-based)
    String popStr            // contents of current popup item as string
    ...
End
```

The "`: PopupMenuControl`" puts the procedure in the Procedure pop-up menu in the PopupMenu Control dialog.

The action procedure for a PopupMenu control can also use a predefined structure **WMPopupAction** as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a PopupMenu control, otherwise it will use the old-style method.

A PopupMenu action procedure using a structure has the format:

```
Function newActionProcName(PU_Struct)
    STRUCT WMPopupAction &PU_Struct
    ...
End
```

For a PopupMenu control, the **WMPopupAction** structure has members as described in the following table:

WMPopupAction Structure Members

Member	Description
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.
<code>STRUCT Rect winRect</code>	Local coordinates of host window.

WMPopupMenu Structure Members

Member	Description						
STRUCT Rect ctrlRect	Enclosing rectangle of the control.						
STRUCT Point mouseLoc	Mouse location.						
Int32 eventCode	Event that executed the procedure.						
	<table> <tr> <th>eventCode</th><th>Event</th></tr> <tr> <td>-1</td><td>Control being killed</td></tr> <tr> <td>2</td><td>Mouse up</td></tr> </table>	eventCode	Event	-1	Control being killed	2	Mouse up
eventCode	Event						
-1	Control being killed						
2	Mouse up						
Int32 eventMod	Bitfield of modifiers. See description of MODIFIERS: <i>flags</i> for SetWindow under Unnamed Hooks on page V-505.						
String userdata	Primary (unnamed) user data. If this changes, it is written back automatically.						
Int32 popNum	Item number currently chosen (1-based).						
char popStr[MAXCMDLEN]	Contents of current popup item.						

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

The value string must be capable of being executed at any time. The expression is stored and executed when the menu is activated to fill the menu before the menu is displayed. This way, a function that returns a list of items, such as **WaveList** or **TraceNameList** can be used to make a pop-up menu that reflects conditions at the time it is used.

However, execution will occur outside the routine that creates the pop-up menu control, so you must not use local variables in the expression.

In pop-up menus, the `#"` syntax (see **When Dependencies are Updated** on page IV-174) permits use of a string expression. Normally, the `#` prefix signifies that the following text must be a literal quoted string. But here, the text can also be a string expression that is evaluated at runtime to obtain the final expression for the pop-up menu. In other words, there is a level of indirection. For example:

```
Function/S sf()
    return "Red;Blue;Green;"
End

Function Panel0()
    NewPanel /W=(150,50,478,250)
    PopupMenu popup0,pos={1,2},size={47,20}
    String s="sf()"
    PopupMenu popup0,mode=1,value= #s + "+\"yellow;\\""
End
```

Colors, Color Tables, Line Styles, Markers, and Patterns

You can create PopupMenu controls for color, color tables, line style (dash modes), markers, and patterns. To do so, simply specify the value string as one of `"*COLORPOP*", "*COLORTABLEPOP*", "*COLORTABLEPOPNONAMES*", "*LINESTYLEPOP*", "*MARKERPOP*",` or `"*PATTERNPOP*"`. In these modes the body of the control will contain a color box, a color table (gradient), a line style sample, a marker, or a pattern sample.

For these special pop-up menus, `mode=0` ("Title in Box" checked) is not used.

For a line style pop-up menu, the mode value is the line style number plus one. Thus line style 0 (a solid line) is `mode=1`.

For a marker pop-up, the mode value is the marker number plus one, and marker 0 (the + marker) is `mode=1`.

For a pattern pop-up, the mode value is the **SetDrawEnv** fillPat number minus 4, so mode=1 corresponds to fillpat=5, the SW-NE lines fill pattern shown above.

For a color table pop-up, the mode value is the CTabList() index plus 1, so mode=1 corresponds to the first item in the list returned by **CTabList**, which is "Grays":

```
ControlInfo $ctrlName // Sets V_Value
Print StringFromList(V_Value-1,CTabList()) // Prints "Grays"
```

ControlInfo also returns the color table name in S_Value.

To set the pop-up to a given color table name, you can use code like this:

```
Variable m = 1 + WhichListItem(ctabName, CTabList())
PopupMenu $ctrlName mode=m
```

For color pop-up menus, you set the current value using the popColor=(*r, g, b*) keyword. On output (via the popStr parameter of your action procedure or via the S_value output from **ControlInfo**) the color is encoded as "(*r,g,b*)" where *r, g*, and *b* are numbers. To get these numerical values, you can extract them from the string using the MyRGBstrToRGB function below or use ControlInfo which sets V_Red, V_Green, V_Blue. The following example demonstrates the line style and color pop-up menus. To run the example, copy the following code to the procedure window of a new experiment and then run the panel macro.

```
Window Panel0() : Panel
  PauseUpdate; Silent 1 // building window ...
  NewPanel /W=(150,50,400,182)
  PopupMenu popup0,pos={74,31},size={96,20},proc=ColorPopupMenuProc,title="colors"
  PopupMenu popup0,mode=1,popColor= (0,65535,65535),value= " *COLORPOP*"
  PopupMenu popup1,pos={9,68},size={221,20},proc=LSytlePopupMenuProc,title="line styles"
  PopupMenu popup1,mode=1,value= " *LINESTYLEPOP*"
EndMacro
```

```
Function ColorPopupMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
  String ctrlName
  Variable popNum
  String popStr

  Variable r,g,b
  MyRGBstrToRGB(popStr,r,g,b) // One way to get r, g, b
  print popStr," gives: ",r,g,b

  ControlInfo $ctrlName // Another way: sets V_Red, V_Green, V_Blue
  Printf "ControlInfo returned (%d,%d,%d)\r", V_Red, V_Green, V_Blue
End
```

// Take (r,g,b) string and extract out numeric r,g,b values

```
Function MyRGBstrToRGB(rgbStr,r,g,b)
  String rgbStr
  Variable &r, &g, &b

  r= str2num(rgbStr[1,inf])
  variable spos= strsearch(rgbStr,"",0)
  g= str2num(rgbStr[spos+1,inf])
  spos= strsearch(rgbStr,"",spos+1)
  b= str2num(rgbStr[spos+1,inf])
  return 1
End
```

```
Function LSytlePopupMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
  String ctrlName
  Variable popNum
  String popStr

  print "style:",popNum-1
End
```

Popvalue Keyword

There are times when the displayed value cannot be determined and saved such that it can be displayed when the pop-up menu is recreated. For instance, because window recreation macros are evaluated in the root folder, a pop-up menu of waves may not contain the correct list when a panel is recreated. That is, the intention may be to have the menu show a particular wave from a data folder other than root. When the panel recreation macro runs, the function that lists waves will list waves in the root data folder. The desired selection may be wrong or nonexistent.

Similarly, a pop-up menu of fonts may need to display a particular font upon recreation on a different computer having a different list of fonts. The mode=*m* keyword probably won't pick the correct font from the new list.

PopupMenuControl

The solution to these problems is to save the correct selection with the `popvalue=valueStr` keyword. The list function will not be executed when the menu is first created. If the menu is popped, the list function will be evaluated, and the correct list will be displayed then.

It is a good idea to set the `mode=m` keyword to the correct number, if it is known. That way, when the menu is popped the correct item is chosen.

Normally you can let Igor redraw the pop-up menu when it redraws the graph or control panel containing it. However, there are situations in which you may want to force the pop-up menu to be redrawn. This can be done using the **ControlUpdate** operation.

See Also

PopupMenuControl

PopupMenuControl

PopupMenuControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined pop-up menu control. See **Procedure Subtypes** on page IV-149 for details.

PossiblyQuoteName

PossiblyQuoteName (nameStr)

The PossiblyQuoteName function returns the input name string if it conforms to the rules of standard wave or Data Folder names. If it does not, then the name is returned in single quotes. This is used when generating a command string that you will pass to the Execute command. You might get the input name string from a function such as **NameOfWave** or **CsrXWave**.

Examples

```
Print PossiblyQuoteName("wave0")           // prints wave0
Print PossiblyQuoteName("wave 0")          // prints 'wave 0'
```

Details

See **Programming with Liberal Names** on page IV-121 for an example.

Preferences

Preferences [/Q] [newPrefsState]

The Preferences operation sets or displays the state of user preferences.

User preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, procedure windows, and the command window. They also affect the appearance of waves appended to graphs and tables, and objects appended to layouts.

Parameters

If *newPrefsState* is present, it sets the state of user preferences as follows:

<i>newPrefsState</i> =0:	Preferences off (use factory defaults).
<i>newPrefsState</i> =1:	Preferences on.

If *newPrefsState* is omitted, the state of user preferences is printed in the history area.

Flags

/Q	Disables printing to the history.
----	-----------------------------------

Details

The Preferences operation sets the variable *V_flag* to the state of user preferences that were in effect *before* the Preferences command executed: 1 for on, 0 for off.

You can also set the state of Preferences with the Misc menu.

Under most circumstances we want procedures to be independent of preferences so that a particular procedure will do the same thing regardless of the state of preferences. To achieve this, preferences are automatically off when you initiate procedure execution. When execution is complete, the state of preferences is restored to what it was before.

If you want preferences to be in effect during procedure execution, you must turn it on with the Preferences operation.

If the preferences setting is changed by a procedure, the effect of the call is propagated down the calling chain. If a macro changes the preferences setting, that change is undone when the macro returns. If a function changes the preferences setting, the change persists after the function returns. However, even with a function, the changed preferences state does not persist when Igor regains control.

Examples

```
Function Test()
    Variable oldPrefState
    Preferences 1; oldPrefState=V_flag           // remember prefs setting
    Make wave0=x
    Display wave0                                // Display uses preferences
    Preferences oldPrefState                     // put prefs back, like a macro would
End
```

Chapter III-17, **Preferences**.

PrimeFactors

PrimeFactors [/Q] inNumber

PrimeFactors calculates the prime factors of *inNumber*. By default factors are printed in the history and are also stored in the wave *W_PrimeFactors* in the current data folder.

Flags

/Q Suppresses printing of factors in the history area.

Details

The largest number that this operation can handle is $2^{32}-1$.

Print

Print [flags] expression [, expression]...

The Print operation prints the evaluated expressions in the history area.

Parameters

An expression can be a wave, a numeric expression (e.g., $3*\pi/4$), a string expression (e.g., "Today is " + date()), or a individual structure element or an entire structure variable.

Flags

/C Evaluates all numeric expressions as complex.
 /D Prints a greater number of digits.
 /F Prints numeric wave data (1D and 2D waves only) using "nice," easily readable formatting.
 /LEN=len Sets the string break length to *len* number of characters (default is 200).
 /S Obsolete. Numeric results are printed with a moderate number of digits whether you use /S or not. To print more digits, use /D.
 /SR Prints a wave subrange for expressions that start as "*waveName*[". Without /SR, such an expression is taken as the start of a numeric expression such as *wave* [3] -*wave* [2]. (You can still use *wave*[*pnt*] but only if it does not start the numeric expression.)
 Wave subrange printing is not done with /F.
 You can specify a single row or column using [*r*] syntax. For example, to print column 4 of a matrix, use:
 Print mymat[][4]

Details

Numeric expressions are always evaluated in double precision. The /D flag just controls the number of digits displayed.

Print determines if an expression is real, complex, or string from the first symbol in the expression. Usually this works fine, but occasionally Print guesses wrong and you may have to rearrange your expression. For example:

```
Print 1+cmplx(1,2)
```

printf

will give an error because the first symbol, "1", is real but the expression should be complex. Changing this to

```
Print cmplx(1,2)+1
```

will work.

Print will break long string expressions into multiline pieces. If there are no natural breaks (carriage returns or semicolons) within a default length, then it will break the string arbitrarily.

The default line length is 200 chars or it can be set using the /LEN flag. The maximum number of characters that can be printed on a line in the History area is 400.

When printing waves, you can use either formatted (specified by /F) or unformatted (default) methods. Unformatted output is in an executable syntax for each printed line: `wave={ }`.

Note: Executing lines printed from floating point waves will not exactly reproduce the source data due to round-off or insufficient digits in the printed output.

Printing formatted wave data gives easily (human) readable output, and works best for small 1D and 2D waves. If the data are too large or in an unsupported format (3D or greater, or the wave is text), then the output will be unformatted. Formatting is done using spaces, so the output will look best in a fixed-width font.

Printed wave data, both formatted and unformatted, are limited to no more than 100 lines of output. When the line limit is exceeded a warning message will be printed at the end of the truncated output. For text waves, output is limited to 50 characters of each string element, and there is no warning when a string is truncated.

See Also

The **printf** operation.

printf

```
printf formatStr [, parameter [, parameter]...]
```

The **printf** operation prints formatted output to the history area.

Parameters

formatStr is a string which specifies the formatting of the output.

The number of parameters depends on the number of conversion specifications in the format string. Lack of agreement between the type of the parameter, string or numeric, and the corresponding conversion specification in *formatStr* yields indeterminate results.

Details

The **printf** operation supports numeric (real only) and string fields from structures. All other field type will cause a compile error.

The *formatStr* contains literal text and conversion specifications.

A conversion specification starts with the % character and ends with a conversion character (for example, g, e, f, d, or s as illustrated below). In between the % and the conversion character you may include one or more flag characters, a field width specifier, and a precision specifier. The first % corresponds to the first parameter, the second % corresponds to the second parameter, etc. If *formatStr* contains no % characters, no parameters are expected.

Here are some simple examples. *numVar* is a numeric variable and *strVar* is a string variable.

```
printf "The answer is: %g\r", numVar
printf "Created wave %s\r", strVar
printf "Created wave %s, %d points\r", strVar, numVar
```

%g is a general-purpose format (floating point or scientific notation) that represents the value of *numVar*. %d is an integer format that represents the value of *numVar*. %s specifies that the corresponding parameter (*strVar*) is a string.

The "\r" in these examples appends a carriage return to the end of the printed text.

Here is a complex example using all of these elements of a conversion specification:

```
printf "%+15.4f\r", 1e6*PI
```

This prints +3141592.6536

The “+” is a flag character that puts a “+” or “-” character in front of the number. The “15” is a field width specifier that prints the number in a field of at least 15 characters. The “4” is a precision specifier that prints four digits after the decimal point. “f” uses a floating point format.

The most common conversions characters are “f” for floating point, “g” for general, “d” for decimal, and “s” for string. They are interpreted as for the printf() function in the C programming language.

The escape codes \t and \r represent the tab and return characters respectively. See **Escape Characters in Strings** on page IV-13 for more information.

The supported flag characters and their meanings are as follows:

-	Left align the result in the field.
+	Put a plus or minus sign before the number.
<space>	Put a space before a positive number.
#	Specifies alternate form for e, f, g, and x formats.

The meaning of the precision specifier depends on the numeric format (%g, %e, %f, %d, etc.) being used:

e, E, f	Precision specifies number of digits after decimal point.
g, G	Precision specifies maximum number of significant digits.
d, o, u, x, X	Precision specifies minimum number of digits.

You can replace both the field width and precision specifiers with an asterisk. This gets the field width or precision specifier from a parameter. For example:

```
printf "%*. *f\r" 4, 3, 1e6*PI
```

means that the field width is 4 and the precision is 3. You could use numeric expressions instead of the literal numbers to control the field width and precision algorithmically.

Here is a complete list of the conversion characters supported by printf:

f	Converts a numeric parameter as [-]ddd.ddd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.
e, E	Converts a numeric parameter as [-]d.ddde+/-dd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If you use “E” instead of “e” then printf uses a capital “E” in the number. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.
g, G	Converts a numeric parameter using “f” or “e” style conversion depending on the magnitude of the number. “e” is used if the exponent is less than -4 or greater than the precision. “G” uses “f” or “E” style conversion. If the # flag is present, a decimal point will be used even if there are no digits to the right of it and trailing zeros will not be removed.
d, o, u	Converts a numeric parameter as a signed decimal integer, unsigned octal integer or unsigned decimal integer, truncating any fractional part. The precision defaults to one and specifies the minimum number of digits to print.
x, X	Converts a numeric parameter as an unsigned hexadecimal integer, truncating any fractional part. The “x” style uses lower case for the hexadecimal numerals “abcdef” where the “X” style uses upper case. The precision defaults to one and specifies the minimum number of digits to print. If the # flag is present, the string “0x” or “0X” is prepended to the number if it is not zero.
s	Converts a string parameter which can contain no more than 1000 characters. If a precision is specified, it sets the maximum number of characters from the string parameter to be printed.
b	WaveMetrics extension. Converts a numeric parameter to binary.
c	Converts a numeric parameter to a single character.
%	Prints a % sign. No parameter is used.
%W	WaveMetrics extension. See description below.

Igor also supports a non-C, WaveMetrics extension to the conversion characters recognized by printf. This conversion specification starts with “%W”. It is followed by a flag digit and a format character. For example, `printf "%W0Ps", 12.345E-6`

prints 12.345000 μ s. In this example, the “%W0” introduces the WaveMetrics conversion specification. The “0” (zero) following the “W” is the flag digit. The “P” that follows is the format specifier character, which prints the number using a prefix, in this case, “ μ ”.

There is only one WaveMetrics format specifier character, “P”, which prints using a prefix such as μ , m, k, or M. It recognizes two flag-digits, “0” or “1”. Option “0” prints with no space between the numeric part and the prefix character while flag “1” prints with 1 space. Numbers greater than tera or less than femto print using a power of ten notation. Here are a few examples:

```
printf "%.2W0PHz", 12.342E6      // prints 12.34MHz
printf "%.2W1PHz", 12.342E6      // prints 12.34 MHz
printf "%.0W0Ps", 12.342E-6       // prints 12 $\mu$ s
printf "%.0W1Ps", 12.342E-9       // prints 12 ns
```

The **sprintf**, **fprintf**, and **wfprintf** operations; **Creating Formatted Text** on page IV-184 and **Escape Characters in Strings** on page IV-13.

PrintGraphs

PrintGraphs [*flags*] *graphSpec* [, *graphSpec*]...

The PrintGraphs operation prints one or more graphs.

PrintGraphs prints one or more graphs on a single page from the command line or from a procedure. The graphs can be overlaid or positioned any way you want.

Parameters

The *graphSpec* specifies the name of a graph to print, the position of the graph on the page and some other options.

Flags

/C=num Renders graphs in black and white (*num*=0) or in color (*num*=1; default).
/D Disables high resolution printing. This flag is of use only on Macintosh. It has no effect on Windows.
/G=grout Specifies grout, the spacing between objects, for tiling in prevailing units.
/I Coordinates are in inches.
/M Coordinates are in centimeters.
/R Coordinates are in percent of page size (see **Examples**).
/S Stacks graphs.
/T Tiles graphs.

Details

Graph coordinates are in inches (*/I*) or centimeters (*/M*) relative to the top left corner of the physical page. If none of these options is present, coordinates are assumed to be in points.

The form of a *graphSpec* is:

graphName [(*left*, *top*, *right*, *bottom*)] [*/F=f*] [*/T*]

Here are some examples:

```
// Take size and position from window size and position.
PrintGraphs Graph0, Graph1
// Specify size and position explicitly.
PrintGraphs/I Graph0(1, 1, 6, 5)/F=1, Graph1(1, 6, 6, 10)/F=1
```

If the coordinates are missing and the */T* or */S* flags are present before *graphSpec* then the graphs are tiled or stacked. If the coordinates are missing but no */T* or */S* flags are present then the graph is sized and positioned based on its position on the desktop.

Finally there are these *graphSpec* options, which appear after the graph name:

/F=f Specifies a frame around the graph.
 f=1: Single frame.
 f=2: Double frame.
 f=3: Triple frame.
 f=4: Shadow box frame.
/T Graph is transparent. This allows special effects when graphs are overlaid.

For this to be effective, the graph and its contents must also be transparent. Graphs are transparent only if their backgrounds are white. Annotations have their own transparent/opaque settings. PICTs may have been created transparent or opaque; an opaque PICT cannot be made transparent.

Examples

You can put an entire *graphSpec* into a string variable and use the string variable in its place. In this case the name of the string variable must be preceded by the \$ character. This is handy for printing from a procedure and also keeps the PrintGraphs command down to a reasonable number of characters. For example:

```
String spec0, spec1, spec2
spec0 = "Graph0(1, 1, 6, 5)/F=1"
spec1 = "Graph1(1, 6, 6, 10)/F=1"
spec2 = "" // PrintGraphs will ignore spec2.
PrintGraphs/I $spec0, $spec1, $spec2
```

If you use a string for a *graphSpec* and that string contains no characters then PrintGraphs will ignore that *graphSpec*.

PrintLayout

PrintLayout [*/C/D*] *winName*

The PrintLayout operation prints the named page layout window.

Parameters

winName is the window name of the page layout to print.

Flags

/C=num Renders graphs, tables, and annotations in black-and-white (*num*=0) or in color (*num*=1; default). It has no effect on pictures, which are colored independently.

/D Prints the layout at the default resolution of the output device. Otherwise it is printed at the highest resolution. This flag is of use only on Macintosh. It has no effect on Windows.

Details

Normally page layouts are printed at the highest available resolution of the output device (printer, plotter, or whatever). On Macintosh, it may not work properly at high resolution with some unusual output devices. If this happens, you can try using the */D* flag to see if it works properly at the default resolution.

PrintNotebook

PrintNotebook [*flags*] *winName*

The PrintNotebook operation prints the named notebook window.

Parameters

winName is the window name of the notebook to print.

Flags

/B=hiResMethod *Macintosh only*; this flag has no effect on Windows.

hiResMethod=1: Print HiRes PICTs using high resolution bitmaps.

hiResMethod=0: Don't print HiRes PICTs using high resolution bitmaps.

hiResMethod=-1: Print using the default method. Prints HiRes PICTs using high resolution bitmaps and is the same as method 1.

/P=(startPage,endPage) Specifies a page range to print. 1 is the first page.

/S=selection *selection*=0: Print entire notebook (default).

selection=1: Print selection only.

Details

If no */B* flag is given, the default method of handling HiRes PICTs is used (*/B*=1). Printing of HiRes PICTs is not well supported on the Macintosh, so by default it prints them using temporary high resolution bitmaps. If a future version of the Mac OS improves in this respect, we will change the default method to print directly.

Chapter III-1, **Notebooks**.

PrintSettings

PrintSettings [/I /M /W=*winName*] [*copySource=source*, *orientation=o*,
margins={left,top,right,bottom}, *scale=s*, *colorMode=m*, *getPrinterList*,
getPrinter, *setPrinter=printerNameStr*, *getPageSettings*, *getPageDimensions*]

The PrintSettings operation gets or sets parameters associated with printing, such as a list of available printers or page setup information for a particular window.

When getting or setting page setup information, PrintSettings acts on a particular window called the destination window. The destination window is the top graph, table, page layout, or notebook window or the window specified by the /W flag.

PrintSettings can not act on page setup records associated with the command window, procedure windows, help windows, control panel, XOP windows, or any type of window other than graphs, tables, page layouts, and notebooks.

The PrintSettings operation services the keywords in the order shown above, not in the order in which they appear in the command. Thus, for example, the getPageSettings and getPageDimensions keywords report the settings after all other keywords are executed.

Flags

/I	Measurements are in inches. If both /I and /M are omitted, measurements are in points.
/M	Measurements are in centimeters. If both /I and /M are omitted, measurements are in points.
/W= <i>winName</i>	Acts on the page setup record of the graph, table, page layout, or notebook window identified by <i>winName</i> . If <i>winName</i> is omitted or if <i>winName</i> is " ", then it used the page setup for the top window.

Keywords

<i>colorMode=m</i>	Sets the color mode for the page setup to monochrome (<i>m</i> =0) or to color (<i>m</i> =1). This keyword does nothing on Macintosh because it is not supported by Mac OS X.
<i>copySource=source</i>	Copies page setup settings from the specified source to the destination window. <i>source</i> can be the name of a graph, table, page layout, or notebook window or it can be one of the following special keywords: Default_Settings: Sets the page setup record to the default for the associated printer as specified by the printer driver. Factory_Settings: Sets the page setup record to the WaveMetrics factory default. This is the page setup you get when creating a new window with user preferences turned off. Preferred_Settings: Sets the page setup record to the user preferred page setup. This is the page setup you get when creating a new window with user preferences turned on. Because there is only one page setup for all graphs and one page setup for all tables, this has no effect when the destination window is a graph or table. It does work for layouts and notebooks.
<i>getPageDimensions</i>	Returns page dimensions via the string variable <i>S_value</i> , which contains keyword-value pairs that can be extracted using NumberByKey and StringByKey . See Details for keyword-value pair descriptions.
<i>getPageSettings</i>	Returns page setup settings in the string variable <i>S_value</i> , which contains keyword-value pairs that can be extracted using NumberByKey and StringByKey . See Details for keyword-value pair descriptions.
<i>getPrinter</i>	Returns the name of the selected printer for the destination window in the string variable <i>S_value</i> . On Macintosh the returned value will be " " if the setPrinter keyword was never used on the destination window. This means that the window will use the operating system's "current printer".
<i>getPrinterList</i>	Returns a semicolon-separated list of printer names in the string variable <i>S_value</i> . Mac OS 9: Does not work and returns an error, although Apple documentation suggests that it should work. Therefore you must use IgorInfo to check what OS you have and not use this keyword with Mac OS 9.

Mac OS X:	Returns a list of printers added through Print Center.
Windows 98:	Returns the names of local printers and network printers. This can take a while.
Windows NT, 2000, and XP:	Returns the names of any local printers and names of network printers to which the user has made previous connections. This should execute quickly.

`margins={left, top, right, bottom}`

Sets the page margins. Dimensions are in points unless /I or /M is used.

The margins are clipped so that they are no smaller than the minimum allowed by the printer driver and no larger than one-half the size of the paper.

The terms *left*, *top*, *right*, and *bottom* refer to the sides of the page after possible rotation for landscape orientation.

Passing zero for all four margins sets the margins to the minimum margin allowed by the printer.

On Macintosh only, passing -1 for all four margins sets the margins to whatever minimum margin is allowed by the printer, even if the printer is changed later. This is how Igor Pro behaved on Macintosh prior to the creation of the PrintSettings operation, when the minimum printer margins were always used.

`orientation=o`

Sets the paper orientation to portrait (*o*=0) or to landscape (*o*=nonzero).

`scale=s`

Sets the page scaling in percent. *s* is clipped to the range 5 to 5000. A value of 50 prints graphics at one-half the normal size. Some printer drivers do not support scaling in which case the scale keyword does nothing. Many Windows printer drivers that do support scaling still do not work with the scale keyword because their scaling support does not use the standard Windows technique.

`setPrinter=printerNameStr`

Sets the selected printer for the destination window.

SetPrinter attempts to preserve orientation, margins, scale, and color mode but other settings may revert to the default state.

On Mac OS 9, this does not work and returns an error, although Apple documentation suggests that it should work. Therefore you must use **IgorInfo** to check what OS you are using and not use this keyword on Mac OS 9.

printerNameStr is a name as returned by the `getPrinterList` keyword and may not be identical to the name displayed in various dialogs. For example, on Mac OS X, the printer name "DESKJET 840C" is returned by `getPrinterList` as "DESKJET_840C". The latter is the "Queue Name" displayed by the Mac OS X Print Center or Printer Setup Utility programs.

If *printerNameStr* is " ", the printer for the destination window is set to the default state. This means different things depending on the operating system:

Mac OS X:	The destination window will use the operating system's "current printer", as if the <code>setPrinter</code> keyword had never been used.
Windows 2000, XP, or later:	The destination window will use the system default printer.
Windows 95, 98, and NT:	Has no effect at all because these operating systems do not provide the necessary support for this feature.

If you receive an error when using `setPrinter`, use the `getPrinterList` keyword to verify that the printer name you are using is correct. Verify that the printer is connected and turned on.

Windows printer names are sometimes UNC names of the form "\\Server\Printer". You must double-up backslashes when using a UNC name in a literal string. See **UNC Paths** on page III-383 for details.

PrintSettings

Details

All graphs in the current experiment share a single page setup record so if you change the page setup for one graph, you change it for all graphs.

All tables in the current experiment share a single page setup record.

Each page layout window has its own page setup record.

Each notebook window has its own page setup record.

The keyword-value pairs for the getPageSettings keyword are as follows:

Keyword	Information Following Keyword
ORIENTATION:	0 if the page is in portrait orientation, 1 if it is in landscape orientation.
MARGINS:	The left, top, right, and bottom margins in points, separated by commas.
SCALE:	The page scaling expressed in percent. 50 means that the graphics are drawn at 50% of their normal size.
COLORMODE:	0 for black&white, 1 for color. This is not supported on Macintosh and always returns 1.

The keyword-value pairs for the getPageDimensions keyword are as follows:

Keyword	Information Following Keyword
PAPER:	The left, top, right, and bottom coordinates of the paper in points, separated by commas. The top and left are negative numbers so that the page can start at (0,0).
PAGE:	The left, top, right, and bottom coordinates of the page in points, separated by commas. The term page refers to the part of the paper inside the margins. The top/left corner of the page is always at (0, 0).
PRINTAREA:	The left, top, right, and bottom coordinates of the page in points, separated by commas. The print area is the part of the paper on which printing can occur, as determined by the printer. This is equal to the paper inset by the minimum supported margins. The top and left are negative numbers so that the page can start at (0,0).

Examples

For an example using the PrintSettings operation, see the PrintSettings Tests example experiment file in the "Igor Pro Folder:Examples:Testing & Misc" folder.

Here are some simple examples showing how you can use the PrintSettings operation.

```
Function GetOrientation(name)          // Returns 0 (portrait) or 1 (landscape)
    String name                        // Name of graph, table, layout or notebook
    PrintSettings/W=$name getPageSettings
    Variable orientation = NumberByKey("ORIENTATION", S_value)
    return orientation
End

Function SetOrientationToLandscape(name)
    String name                        // Name of graph, table, layout or notebook
    PrintSettings/W=$name orientation=1
End

Function/S GetPrinterList()
    // PrintSettings getPrinterList does not work on Mac OS 9
    String info = IgorInfo(3)
    if (strsearch(info,"Macintosh Carbon",0) >= 0)
        return "Default"
    endif
    PrintSettings getPrinterList
    return S_value
End

Function SetPrinter(destWinName, printerName)
    String destWinName, printerName
    // PrintSettings setPrinter does not work on Mac OS 9
    String info = IgorInfo(3)
    if (strsearch(info,"Macintosh Carbon",0) >= 0)
```

```

        return -1
    endif
    PrintSettings/W=$destWinName setPrinter=printerName
    return 0
End

```

PrintTable

PrintTable [**/P=(startPage,endPage)** **/S=selection**] *winName*

The PrintTable operation prints the named table window.

Parameters

winName is the window name of the table to print.

Flags

/P=(startPage,endPage) Specifies a page range to print. 1 is the first page.
 If */P* is omitted all pages are printed unless */S* is used.

/S=selection *selection=0:* Print entire table (default).
 selection=1: Print selection only.

See Also

Chapter II-11, **Tables**.

Proc

Proc *macroName*([*parameters*]) [**:macro type**]

The Proc keyword introduces a macro that does not appear in any menu. Otherwise, it works the same as **Macro**. See **Macro Syntax** on page IV-80 for further information.

ProcedureText

ProcedureText(*macroOrFunctionNameStr* [, *linesOfContext* [, *procedureWinTitleStr*]])

The ProcedureText function returns a string containing the text of the named macro or function as it exists in some procedure file, optionally with additional lines that are before and after to provide context or to collect documenting comments.

Parameters

macroOrFunctionNameStr identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "myModule#myFunction" to specify the static function myFunction in a procedure window that contains a **#pragma ModuleName=myModule** statement.

linesOfContext optionally specifies the number of lines around the function to include in the returned string. The default is 0 (no additional contextual lines of text are returned).

Setting *linesOfContext* to -1 returns lines before the procedure that are not part of the preceding macro or function. Usually these lines are comment lines describing the named procedure. Blank lines are omitted.

Setting *linesOfContext* to a positive number returns that many lines before the procedure and after the procedure. Blank lines are not omitted.

The optional *procedureWinTitleStr* can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf"). The text of the named macro or function in the specified procedure window is returned.

You can use *procedureWinTitleStr* to select one of several static functions with identical names among different procedure windows, even if they do not use a **#pragma moduleName=myModule** statement.

Advanced Parameters

If **SetIgorOption IndependentModuleDev=1**, *procedureWinTitleStr* can also be a title followed by a space and, in brackets, an independent module name. In such cases ProcedureText retrieves function text from the specified procedure window and independent module. (See **The IndependentModule Pragma** on page IV-40 for independent module details.)

For example, in a procedure file containing:

```

#pragma IndependentModule=myIM
#include <Axis Utilities>

```

A call to ProcedureText like this:

```
String text=ProcedureText("HVAxisList",0,"Axis Utilities.ipf [myIM]")
```

will return the text of the HVAxisList function located in the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.

You can see procedure window titles in this format in the Windows→Procedure Windows menu when SetIgorOption IndependentModuleDev=1 and when an experiment contains procedure windows that comprise an independent module, as does #include <New Polar Graphs>.

procedureWinTitleStr can also be just an independent module name in brackets to retrieve function text from any procedure window that belongs to the named independent module:

```
String text=ProcedureText("HVAxisList",0,"[myIM]")
```

See Also

The **ModuleName Pragma** on page IV-40 and The **IndependentModule Pragma** on page IV-40.

The **WinRecreation** and **FunctionList** functions.

ProcGlobal

ProcGlobal#procPictureName

The ProcGlobal keyword is used with Proc Pictures to avoid possible naming conflicts with any other global pictures in the experiment. When you add a picture to an experiment using the Pictures dialog, such a picture is global in scope and may potentially have the same name as a Proc Picture. When a Proc Picture is global (and only then), you should use the ProcGlobal keyword to make sure that the Proc Picture is used with your code and to avoid confusion with pictures in the Pictures dialog.

See Also

See **Proc Pictures** on page IV-44 for details. **Pictures Dialog** on page III-406.

Project

Project [/C={long,lat}/M=method /P={p1,p2,...}] longitudeWave, latitudeWave

The Project operation calculates projections of XY data, which most often are longitude and latitude waves of geographic coordinates. The output waves are W_XProjection and W_YProjection. Longitude and Latitude are in degrees.

Parameters

longitudeWave is the name of the wave supplying the longitude or equivalent coordinates. latitudeWave is the name of the wave supplying the latitude or equivalent coordinates.

Flags

/C={long,lat}	Specifies longitude and latitude center of projection. By default long=0 and lat=90.
/M=method	Indicates the type of projection. method can be one of the following: 0: Orthographic (default). 1: Stereographic. 2: Gnomonic. 3: General perspective. 4: Lambert equal area. 5: Equidistant. 6: Mercator. 7: Transverse Mercator. 8: Albers Equal Area conic.
/P={p1,p2,...}	One or more parameters required by a particular projection. See the following sections for parameters required by the various projections.

Gnomonic

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that $\cos(c)$ in Eq. (5-3) of Snyder is greater than the specified parameter:

```
/P={cos(c)}
```

The actual transformation uses Eqs. (22-4) and (22-5) of Snyder with k' given by (22-3).

General Perspective

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that $\cos(c)$ in Eq. (5-3) of Snyder is greater than the specified parameter.

The actual transformation uses Eqs. (22-4) and (22-5) with k' given by (22-3). Here we specify the height H is units of sphere radius. The tilt of the plane is specified by ω and γ following the notation of Snyder page 175.

The parameters actually specified by the command are:

$/P=\{H, \omega, \gamma, \text{deltax}, \text{deltay}\}$

H is the height (in radii) above the surface of the earth, γ is the azimuth east of north of the Y axis, and ω is the tilt angle or the angle between the projection plane and the tangent plane. The x output will be limited to $\pm \text{deltax}$ and the y output will be limited to the range $\pm \text{deltay}$.

Mercator

This projection requires the following parameters:

$/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}\}$

If $/P$ is not specified, the default is $\{0, 360, -90, 90\}$

Note that this projection flips the sign of y when $\cos(\text{longitude} - \text{long}_0)$ changes sign. If you are plotting a continuous path in which consecutive points exhibit the sign change, you should add a NaN entry in the wave so that the path does not wrap.

Albers Equal Area Conic

This projection requires:

$/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}, \text{Phi1}, \text{Phi2}\}$

Phi1 and Phi2 are the specification of the two standard parallels, the other four parameters determine the boundary of the map area for display.

References

Snyder, John P., *Map Projections—A Working Manual*, U.S.G.S. Professional Paper 1395, U.S. Government Printing Office, Washington D.C., 1987, reprinted 1989, 1994, 1997 with corrections.

Prompt

Prompt *variableName*, *titleStr* [, *popup*, *menuListStr*]

The Prompt command is used in functions for the simple input dialog and in macros for the missing parameter dialog. Prompt supplies text to describe *variableName* to the user, and optionally provides a pop-up menu of choices for the value of *variableName*.

Parameters

variableName is the name of a macro input parameter or function variable.

titleStr is a string or string expression containing the text to present in the dialog to describe what *variableName* is. This string should be short if the number of items exceeds 5 (when the dialog uses two columns).

The optional keyword **popup** is used to provide a pop-up list of choices for the values of *variableName*. If **popup** is used, then *menuListStr* is required.

menuListStr is a string or string expression that contains a semicolon-separated list of choices for the value of *variableName*. If *variableName* is a string, choosing from this list will set the string to the selection. If it is a numeric variable, then it is set to the item number of the selection (if the first item is selected, the numeric variable is set to 1, etc.).

Details

In macros, the Prompt command must follow the macro Variable and String parameter declarations, and precede any executing macro statements.

Prompt may be used anywhere within the body of a function, but must precede any DoPrompt that uses the Prompt variable.

PulseStats

menuListStr may be continued on succeeding lines only in macros, as long as no comment is appended to the Prompt line. The additional lines should start with a semicolon, and are appended to the *menuListStrs* on preceding lines.

Examples

```
Macro SampleMacro(xvar,wv)
  Variable xvar
  String wv
  Prompt xvar,"enter x range"
  Prompt wv,"the wave",popup,WaveList("",";","")+";_none_"
  // (your code here)
End
```

Note that there must be no blank lines between the Macro declaration and the last Prompt statement.

This macro will produce the following dialog if it is chosen from the Macros menu:

See Also

Also see **The Simple Input Dialog** on page IV-104; the **DoPrompt** and **popup** keywords.

PulseStats

PulseStats [*flags*] *waveName*

The PulseStats operation produces simple statistics on a region of the named wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds.

PulseStats handles other cases in which there are only one or two edges.

Flags

/A=n

Determines *startLevel* and *endLevel* automatically by averaging *n* points centered at *startX* and *endX*. This does not work in case 2, which requires that you use the */L* flag. Default is */A=1*.

/B=box	Sets box size for sliding average. This should be an odd number. If /B=box is omitted or box equals 1, no averaging is done.
/F=f	Specifies levels 1, 2, and 3 as a fraction of (<i>endLevel</i> - <i>startLevel</i>): $\text{level1} = \text{level2} = \text{level3} = f * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$ <i>f</i> must be between 0 and 1. The default value is 0.5 which sets the levels to midway between the base levels.
/L=(<i>startLevel</i> , <i>endLevel</i>)	Sets <i>startLevel</i> and <i>endLevel</i> explicitly.
/M=dx	Sets minimum edge width. Once an edge is found, the search for the next edge starts <i>dx</i> units beyond the found edge. Default <i>dx</i> is 0.
/P	Output edge locations (see Details) are set in terms of point number. If /P is omitted, edge locations are set in terms of X values.
/Q	Prevents results from being printed in history and prevents error if edge is not found.
/R=(<i>startX</i> , <i>endX</i>)	Specifies an X range of the wave to search. You may exchange <i>startX</i> and <i>endX</i> to reverse the search direction.
/R=[<i>startP</i> , <i>endP</i>]	Specifies a point range of the wave to search. You may exchange <i>startP</i> and <i>endP</i> to reverse the search direction. If you specify the range as /R=[<i>startP</i>] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is searched.
/T=dx	Forces search in two directions for a possibly more accurate result. <i>dx</i> controls where the second search starts.

Details

The /B=box, /T=dx, /P and /Q flags behave the same as for the **FindLevel** operation.

PulseStats considers a region of the input wave between two X locations, called *startX* and *endX*. *startX* and *endX* are set by the /R=(*startX*,*endX*) flag. If this flag is missing, *startX* and *endX* default to the start and end of the entire wave.

The *startLevel* and *endLevel* values define the base levels of the pulse. You can explicitly set these levels with the /L=(*startLevel*, *endLevel*) flag or you can let PulseStats find the base levels for you by using the /A=*n* flag. With this flag, PulseStats determines *startLevel* and *endLevel* by averaging *n* points centered at *startX* and at *endX*. In case 2, you must use /L=(*startLevel*, *endLevel*) since *startLevel* is not at point 0.

Given *startLevel* and *endLevel* and an *f* value (which you can set with the /F=*f* flag), PulseStats computes level1, level2 and level3 which are always equal. With the default *f* value of 0.5, level1 is midway between *startLevel* and *endLevel*.

With these levels defined, PulseStats searches the wave from *startX* to *endX* looking for one, two or three level crossings. PulseStats sets the following variables:

V_flag	0: All three level crossings were found. 1: One or two level crossings were found. 2: No level crossings were found.
V_PulseLoc1	X location where level1 was found.
V_PulseLoc2	X location where level2 was found.
V_PulseLoc3	X location where level3 was found.
V_PulseLv10	<i>startLevel</i> value.
V_PulseLv1123	Level1 value that is the same as level2 and level3.
V_PulseLv14	<i>endLevel</i> value.
V_PulseAmp4_0	Pulse amplitude (<i>endLevel</i> - <i>startLevel</i>).
V_PulseWidth2_1	Left pulse width (x distance between point 2 and point 1).
V_PulseWidth3_2	Right pulse width (x distance between point 3 and point 2).
V_PulseWidth3_1	Pulse period (x distance between point 3 and point 1).
V_PulsePolarity	Trend of the edge at point 1 (-1 if decreasing, +1 if increasing).

X locations and distances are in terms of the X scaling of the source wave, unless you use the /P flag in which case they are in terms of point number.

PutScrapText

If any level crossings are missing then PulseStats sets the associated variables to NaN (Not a Number). If one crossing is missing, variables depending on point 3 are set to NaN. If two crossings are missing, variables depending on points 2 and 3 are set to NaN. If all crossings are missing, variables depending on points 1, 2, and 3 are set to NaN. You can use the numtype function to test a variable to see if it is NaN.

The PulseStats operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The **FindLevel** operation about the /B=box, /T=dx, /P and /Q flags, **EdgeStats** and the **numtype** function.

PutScrapText

PutScrapText *textStr*

The PutScrapText operation places *textStr* on the Clipboard (aka “scrap”). This text will be used when the user subsequently chooses Paste from the Edit menu.

Details

All contents of the Clipboard (including pictures) are cleared before the text is placed there.

Examples

Put two lines of text into the Clipboard:

```
String text = "This is the first line.\rAnd this is the second."
PutScrapText text
```

Empty the Clipboard:

```
PutScrapText ""
```

See Also

The **GetScrapText** function and the **SavePICT** operation.

q

q

The q function returns the current column index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled column index is available as the y function.

Details

Unlike **p**, outside of a wave assignment statement, q does not act like a normal variable.

See Also

Waveform Arithmetic and Assignments on page II-80.

For other dimensions, the **p**, **r**, and **s** functions.

For scaled dimension indices, the **x**, **y**, **z** and **t** functions.

qcsr

qcsr(*cursorName* [, *graphNameStr*])

The qcsr function can be used with cursors on images or waterfall plots to return the column number. It can also be used with free cursors to return the relative Y coordinate.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **vcscr**, **xcscr**, and **zcscr** functions.

Quit

Quit [/N/Y]

The Quit operation quits Igor Pro.

Flags

/N Quits without saving changes and without dialog.
/Y Saves current experiment before quitting without putting up dialog unless current experiment is "Untitled".

r

r

The r function returns the current layer index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled layer index is available as the z function.

Details

Unlike **p**, outside of a wave assignment statement, r does not act like a normal variable.

See Also

Waveform Arithmetic and Assignments on page II-80. For other dimensions, the **p**, **q**, **s**, and **t** functions. For scaled dimension indices, the **x**, **y**, **z**, and **t** functions.

r2polar

r2polar(z)

The r2polar function returns a complex value in polar coordinates derived from the complex value *z*, which is assumed to be in rectangular coordinates. The magnitude is stored in the real part and the angle (in radians) is stored in the imaginary part of the returned complex value.

Examples

Assume waveIn and waveOut are complex.

```
waveOut= r2polar(waveIn)
```

sets each point of waveOut to the polar coordinates derived from the real and imaginary parts of waveIn.

You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

See Also

The functions **cmplx**, **conj**, **imag**, **p2rect**, and **real**.

RatioFromNumber

RatioFromNumber [*flags*] *num*

The RatioFromNumber operation computes two integers whose ratio is equal to $num \pm maxError$ (/MERR flag). The ratio is returned in V_numerator and V_denominator.

Parameters

num is the number to approximate by V_numerator/V_denominator.

Flags

/MERR=*maxError* Specifies the maximum tolerable error. The computed ratio differs from *num* by no more than *maxError* (default value is $num * 1e-6$).
maxError must be a value between 0 and *num*. See Details about setting *maxError* to 0.
/MITS = *maxIterations* Keeps returned values small by specifying a small number for *maxIterations*.
maxIterations must be a value between 1 and 32767 (default is 100).
/V[=*v*] Prints output variables to history.
v=1: Prints variables (same as /V).
v=0: Nothing printed (same as no /V).

Details

Setting /MERR = 0 computes a maximally accurate ratio. The returned values can be surprisingly large:

ReadVariables

```
·RatioFromNumber/V/MERR=0 (1/1666)
  V_numerator= 4398046511104; V_denominator= 7.3271454874993e+15;
  ratio= 0.00060024009603842; V_difference= 0;
```

Using the default /MERR returns the expected 1 and 1666. The difference is attributable to floating-point roundoff errors.

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking $num - (V_numerator/V_denominator)$ against /MERR.

RatioFromNumber sets the following output variables:

V_difference $V_numerator/V_denominator - num$ (positive if the approximation is too big).

V_flag 0: $V_difference$ less than or equal to /MERR.

 1: $V_difference$ greater than /MERR.

V_numerator, V_denominator

 Values for the numerator and denominator. The ratio of $V_numerator/V_denominator$ approximates num .

Examples

```
·RatioFromNumber/V pi
  V_numerator= 355; V_denominator= 113; ratio= 3.141592920354;
  V_difference= 2.6676418940497e-07;
·RatioFromNumber/V/MITS=2 pi
  V_numerator= 22; V_denominator= 7; ratio= 3.1428571428571;
  V_difference= 0.0012644892673497;
```

See Also

The **gcd** and **trunc** functions.

ReadVariables

ReadVariables

The ReadVariables operation reads variables into an experiment.

ReadVariables is used automatically when you open an experiment. You need not invoke it.

real

real(z)

The real function returns the real component of the complex value z .

See Also

The functions **cmplx**, **conj**, **imag**, **p2rect**, and **r2polar**.

Redimension

Redimension [**flags**] **waveName** [, **waveName**]...

The Redimension operation remakes the named waves, preserving their contents as much as possible.

Flags

/B Converts waves to 8-bit signed integer or unsigned integer if /U is present.

/C Converts real waves to complex.

/D Converts single precision waves to double precision.

/E=e e=0: No special action (default).

 e=1: Force reshape without converting or moving data.

 e=2: Perform endian swap. (See **FBinRead** for a discussion of endian byte ordering.)

/I Converts waves to 32-bit signed integer or unsigned integer if /U is present.

/N=n n is the new number of points each wave will have. Multidimensional waves are converted to 1 dimension.

/N=($n1, n2, n3, n4$)

$n1, n2, n3, n4$ specify the number of rows, columns, layers, and chunks each wave will have.

 Trailing zeros can be omitted (e.g., /N=($n1, n2, 0, 0$) can be abbreviated as /N=($n1, n2$)). If any dimension size is to remain unchanged, pass -1 for that dimension.

/R	Converts complex waves to real by discarding the imaginary part.
/S	Converts double precision waves to single precision.
/U	Converts integer waves to unsigned.
/W	Converts waves to 16-bit integer (unsigned integer if /U is present).

As a replacement for the above number type flags you can use `/Y=numType` to set the number type as an integer code. See the **WaveType** function for code values. Do not use `/Y` in combination with other type flags. This technique cannot be used to change the number type without changing the real/complex setting.

Details

The waves must already exist. New points in waves that are extended are zeroed.

In general, Redimension does not move data from one dimension to another. For instance, if you have a 6x6 matrix wave, and you would like it to be 3x12, the rows have been shortened and the data for the last three rows is lost.

As a special case, if converting to or from a 1D wave, Redimension will leave the data in place while changing the dimensionality of the wave. For example, you can use Redimension to convert a 36-element 1D wave into a 6x6 matrix in which the elements in the first column (column 0) are the first 6 elements of the 1D wave, the elements of the second column are the next 6, etc. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks.

Examples

Reshaping a 1D wave having 4 elements to make a 2x2 matrix:

Make/N=4 vector=x

Redimension/N=(2,2) vector

See Also

Lists of Values on page II-82; the **DeletePoints** and **Make** operations.

Remove

Remove

When interpreting a command, Igor treats the Remove operation as **RemoveFromGraph**, **RemoveFromTable**, or **RemoveFromLayout**, depending on the target window. This does not work when executing a user-defined function. Therefore, we recommend that you use **RemoveFromGraph**, **RemoveFromTable**, or **RemoveLayoutObjects** rather than Remove.

RemoveByKey

RemoveByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])

The RemoveByKey function returns *kwListStr* after removing the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use RemoveByKey to remove information from a string containing a "key1:value1;key2:value2;" or "key1=value1,key2=value2," style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found then *kwListStr* is returned unchanged.

keySepStr, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

Details

keyStr is limited to 255 characters.

kwListStr is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The key, the *keySepStr*, and the text up to and including the next *listSepStr* (if any) are removed from the returned string.

RemoveContour

If the resulting string contains only *listSepStr* characters, then an empty string (" ") is returned.

kwListStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

Examples

```
Print RemoveByKey("AKEY", "AKEY:123;BKEY:val") // prints "BKEY:val"
Print RemoveByKey("AKEY", "akey=1;BK=b;", "=") // prints "BK:b;"
Print RemoveByKey("AKEY", "AKEY=1,BK=b,", "=", ",") // prints "BK:b,"
Print RemoveByKey("ckey", "CKEY:1;BKEY:2") // prints "BKEY:2"
Print RemoveByKey("ckey", "CKEY:1;BKEY:2", ":", ";", 1) // prints "AKEY:1;BKEY:2"
```

See Also

The **NumberByKey**, **StringByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

RemoveContour

RemoveContour [*/W=winName*] *contourInstanceName* [, *contourInstanceName*]...

The RemoveContour operation removes the traces, and releases memory associated with the contour plot of *contourInstanceName* in the target or named graph.

Parameters

contourInstanceName is usually simply the name of a wave. More precisely, *contourInstanceName* is a wave name, optionally followed by the # character and an instance number to identify which contour plot of a given wave is to be removed.

Flags

/W=winName Removes contours from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

If the axes used by the contour plot are no longer in use, they will also be removed.

An contour instance name in a string can be used with the \$ operator to specify *imageInstance*.

Examples

```
Display;AppendMatrixContour zw //new graph, contour of zw matrix
AppendMatrixContour zw //two contours of zw
RemoveContour zw#1 //remove the second contour
```

See Also

The **AppendMatrixContour** and **AppendXYZContour** operations.

RemoveEnding

RemoveEnding(*str* [, *endingStr*])

The RemoveEnding function removes one character from the end of *str*, or it removes the *endingStr* from the end of *str*.

endingStr is optional. If missing, one character is removed from the end of *str*.

Details

endingStr is compared to the end of *str* using a case insensitive comparison (such as **cmpstr** uses). If the end of *str* does not match *endingStr*, the unaltered *str* is returned.

Examples

```
Print RemoveEnding("123")           // prints "12"
Print RemoveEnding("no semi" , ";") // prints "no semi"
Print RemoveEnding("trailing semi;" , ";") // prints "trailing semi"
Print RemoveEnding("file.txt" , ".TXT") // prints "file"
```

See Also

The **cmpstr** and **ParseFilePath** functions.

RemoveFromGraph

RemoveFromGraph [/W=*winName*/Z] *traceName* [, *traceName*]...

The RemoveFromGraph operation removes the specified wave traces from the target or named graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters

traceName is usually the name of a wave.

More precisely, *traceName* is a wave name, optionally followed by the # character and an instance number. It is also referred to as a "trace". See **Examples**.

Flags

/W=*winName* Removes traces from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
 When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z Suppresses errors if specified trace or image is not on the graph.

Details

Up to 100 *traceNames* may be specified, subject to the 400 character command limit.

If the axes used by the given trace are not in use after removing the trace, they will also be removed.

A string containing a trace name can be used with the \$ operator to specify *traceName*.

Note that removing all the contour traces from a contour plot is not the same as removing the contour plot itself. Use the **RemoveContour** operation.

Examples

The command:

```
Display myWave,myWave;Modify mode(myWave#1)=6
```

appends two instances of myWave to the graph. The first/backmost instance of myWave is instance 0, and its trace name is just myWave as a synonym for myWave#0. The second or frontmost instance of myWave is myWave#1 and it is displayed with the cityscape mode.

To remove the second instance from the graph requires the command:

```
RemoveFromGraph myWave#1
```

or

```
String MyTraceName="myWave#1"
RemoveFromGraph $MyTraceName
```

RemoveFromLayout

RemoveFromLayout *objectSpec* [, *objectSpec*]...

Deprecated — use **RemoveLayoutObjects**.

The RemoveFromLayout operation removes the specified objects from the top layout.

Parameters

objectSpec is either an object name (e.g., Graph0) or an *objectName* with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

See Also

The **RemoveLayoutObjects** operation.

RemoveFromList

RemoveFromList(*itemOrListStr*, *listStr* [, *listSepStr* [, *matchCase*]])

The RemoveFromList function returns *listStr* after removing the item or items specified by *itemOrListStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

If *itemOrListStr* contains multiple items, they should be separated by the *listSepStr* character, too.

Use RemoveFromList to remove item(s) from a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

If all items in *itemOrListStr* are not found or if any of the arguments is "" then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case the empty string is returned).

listSepStr and *matchCase* are optional; their defaults are ";" and 1 respectively.

Details

itemStr may have any length.

listStr is searched for an instance of the item string(s) bound by *listSepStr* on the left and right. The item and any trailing *listSepStr* (if any) are removed from the returned string.

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

listStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are case-sensitive. Searches for *items* in *itemOrListStr* are usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparisons case insensitive.

Only the first character of *listSepStr* is used.

If *matchCase* is specified, then *listSepStr* must also be specified.

Examples

```
Print RemoveFromList("wave1", "wave0;wave1;")           // prints "wave0;"
Print RemoveFromList("wave1", ";wave1;;;")              // prints ""
Print RemoveFromList("KEY=joy", "AX=3,KEY=joy", ",")      // prints "AX=3,"
Print RemoveFromList("fred", "fred\twilma", "\t")        // prints "wilma"
Print RemoveFromList("fred;barney", "fred;wilma;barney") // prints "wilma;"
Print "X"+RemoveFromList("",";;;")+ "Y"                  // prints "XY"
Print RemoveFromList("FRED", "fred;wilma")               // prints "fred;wilma"
Print RemoveFromList("FRED", "fred;wilma", ";", 0)        // prints "wilma"
```

See Also

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **UpperStr**, **VariableList**, and **WaveList** functions.

RemoveFromTable

RemoveFromTable [/W=*winName*] *columnSpec* [, *columnSpec*]...

The RemoveFromTable operation removes the specified columns from the top table.

Parameters

columnSpecs are the same as for the **Edit** operation; usually they are just the names of waves.

Flags

/W=*winName* Removes columns from the named table window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

Edit about *columnSpecs*, and **AppendToTable**.

RemoveImage

RemoveImage [/W=*winName*/Z] *imageInstance* [, *imageInstance*]...

The RemoveImage operation removes the given image from the target or named graph.

Parameters

imageInstance is usually simply the name of a wave. More precisely, *imageInstance* is a wave name, optionally followed by the # character and an instance number to identify which image of a given wave is to be removed.

Flags

/W=*winName* Removes an image from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. Must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z Suppresses errors if specified image is not on the graph.

Details

If the axes used by the given image are not in use after removing the image, they will also be removed.

An image name in a string can be used with the \$ operator to specify *imageInstance*.

See Also

The **AppendImage** operation.

RemoveLayoutObjects

RemoveLayoutObjects [/W=*winName*/Z] *objectSpec* [, *objectSpec*]

The RemoveLayoutObjects operation removes the specified object or objects from the top page layout, or from the layout specified by the /W flag.

Unlike the RemoveFromLayout operation, RemoveLayoutObjects can be used in user-defined functions. Therefore, RemoveLayoutObjects should be used in new programming.

Parameters

objectSpec is either an object name (e.g., Graph0) or an *objectName* with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

Flags

/W=*winName* *winName* is the name of the page layout window from which the object is to be removed. If /W is omitted or if *winName* is \$ " ", the top page layout is used.

/Z Does not report errors if the specified layout object does not exist.

See Also

NewLayout, **AppendLayoutObject** and **ModifyLayout**.

RemoveListItem

RemoveListItem(*itemNum*, *listStr* [, *listSepStr*])

The RemoveListItem function returns *listStr* after removing the item specified by the list index *itemNum*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;". *itemNum* should be a number between 0 (the index of the first item in a list) and ItemsInList(*listStr*) - 1.

RemoveListItem removes an item from a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

listSepStr is optional. If missing, *listSepStr* is presumed to be ";".

Details

RemoveListItem differs from **RemoveFromList** in that RemoveListItem specifies the item to be removed by index and removes only that item, while RemoveFromList specifies the item to be removed by value, and removes all matching items.

If *itemNum* less than 0 or greater than ItemsInList(*listStr*) - 1, or if *listSepStr* is " " then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case the empty string is returned).

RemovePath

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

listStr is treated as if it ends with a *listSepStr* even if it doesn't. Searches for *itemStr* and *listSepStr* are case-sensitive.

Only the first character of *listSepStr* is used.

Examples

```
Print RemoveListItem(1, "wave0;wave1;w2;")           // prints "wave0;w2;"
Print RemoveListItem(0, "wave1;;;")                   // prints ""
Print RemoveListItem(1, "AX=3,KEY=joy", ",",")         // prints "AX=3,"
Print RemoveListItem(1, "fred\twilma", "\t")          // prints "fred\t"
```

See Also

The **AddListItem**, **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveFromList**, **StringFromList**, **StringList**, **TraceNameList**, **VariableList**, **WaveList**, and **WhichListItem** functions.

RemovePath

RemovePath [/A/Z] *pathName*

The RemovePath operation removes a path from the list of symbolic paths. RemovePath is an old name for the new **KillPath** operation, which we recommend you use instead.

Rename

Rename *oldName*, *newName*

The Rename operation renames waves, strings, or numeric variables from *oldName* to *newName*.

Parameters

oldName may be a simple object name or a data folder path and name. *newName* must be a simple object name.

Details

You can not rename an object using a name that already exists. The following will result in an error:

```
Make wave0, wave1
// Rename wave0 and overwrite wave1.
Rename wave0, wave1           // This will not work.
```

However, you can achieve the desired effect as follows:

```
Make wave0, wave1
Duplicate/O wave0, wave1; KillWaves wave0
```

See Also

The **Duplicate** operation.

RenameDataFolder

RenameDataFolder *sourceDataFolderSpec*, *newName*

The RenameDataFolder operation changes the name of the source data folder to the new name.

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

newName is just the new name for the data folder, without any path.

Details

RenameDataFolder generates an error if the new name is already in use as a data folder contained within the source data folder.

Examples

```
RenameDataFolder root:foo,foo2           // Change name of foo to foo2
```

See Also

Chapter II-8, **Data Folders**.

RenamePath

RenamePath *oldName*, *newName*

The RenamePath operation renames an existing symbolic path from *oldName* to *newName*.

See Also

Symbolic Paths on page II-30

RenamePICT

RenamePICT *oldName*, *newName*

The RenamePICT operation renames an existing picture to from *oldName* to *newName*.

See Also

Pictures on page III-405.

RenameWindow

RenameWindow *oldName*, *newName*

The RenameWindow operation renames an existing window or subwindow from *oldName* to *newName*.

Parameters

oldName is the name of an existing window or subwindow.

When identifying a subwindow with *oldName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

The DoWindow operation.

ReorderTraces

ReorderTraces [/W=*winName*] *anchortrace*, {*traceA*, *traceB*, ...}

The ReorderTraces operation changes the ordering of graph traces to that specified in the braces.

Flags

/W=*winName* Reorders traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

Igor keeps a list of traces in a graph and draws the traces in the listed order. The first trace drawn is consequently at the bottom. All other traces are drawn on top of it. The last trace is the top one; no other trace obscures it.

ReorderTraces works by removing the traces in the braces from the list and then reinserting them at the location specified by *anchortrace*. If *anchortrace* is not in the braces, the traces in braces are placed before *anchortrace*.

If the list of traces is A, B, C, D, E, F, G and you execute the command

```
ReorderTraces F, {B,C}
```

traces B and C are placed just before F: A, D, E, B, C, F, G.

The result of

```
ReorderTraces E, {D,E,C}
```

is to reorder C, D and E and put them where E was. Starting from the initial ordering results in A, B, D, E, C, F, G.

ReorderTraces generates an error if the same trace is in the list twice.

ReplaceNumberByKey

ReplaceNumberByKey(*keyStr*, *kwListStr*, *newNum* [, *keySepStr* [, *listSepStr* [, *case*]]])

The **ReplaceNumberByKey** function returns *kwListStr* after replacing the numeric value of the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use **ReplaceNumberByKey** to add or modify numeric information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found in *kwListStr*, then the key and the value are appended to the end of the returned string.

keySepStr, *listSepStr*, and *case* are optional; their defaults are ":", ";", and 0 respectively.

Details

The actual string appended is:

[*listSepStr*] *keyStr* *keySepStr* *newNum* *listSepStr*

The optional leading list separator *listSepStr* is added only if *kwListStr* does not already end with a list separator.

keyStr is limited to 255 characters.

kwListStr is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next ";" is replaced by *newNum* after conversion to text using the %.15g format (see **printf** for format conversion specifications).

kwListStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *case* parameter to 0 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *case* is specified, *keySepStr* and *listSepStr* must be specified.

Examples

```
Print ReplaceNumberByKey("K1", "K1:7;", 4)           // prints "K1:4;"
Print ReplaceNumberByKey("k2", "K2=8;", 5, "=")       // prints "K2=5;"
Print ReplaceNumberByKey("K3", "K3:9", 6, ":", ",")    // prints "K3:6,"
Print ReplaceNumberByKey("k3", "K0:9", 6, ":", ",")    // prints "K0:9,k3:6,"
Print ReplaceNumberByKey("k3", "K3:9", 6, ":", ",")    // prints "K3:9,"
Print ReplaceNumberByKey("k3", "K3:9", 6, ":", ",", 1) // prints "k3:9,k3:6,"
```

See Also

The **ReplaceStringByKey**, **NumberByKey**, **StringByKey**, **RemoveByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

ReplaceString

ReplaceString(*replaceThisStr*, *inStr*, *withThisStr* [, *caseSense* [, *maxReplace*]])

The **ReplaceString** function returns *inStr* after replacing any instance of *replaceThisStr* with *withThisStr*.

The comparison of *replaceThisStr* to the contents of *inStr* is case-insensitive. Setting the optional *caseSense* parameter to nonzero makes the comparison case-sensitive.

Usually all instances of *replaceThisStr* are replaced. Setting the optional *maxReplace* parameter limits the replacements to that number.

Details

If *replaceThisStr* is not found, *inStr* is returned unchanged.

If *maxReplace* is less than 1, then no replacements are made. Setting *maxReplace* = Inf is the same as omitting it.

Examples

```
Print ReplaceString("hello", "say hello", "goodbye") // prints "say goodbye"
Print ReplaceString("\r\n", "line1\r\nline2", "")    // prints "line1line2"
Print ReplaceString("A", "an Ack-Ack", "a", 1)       // prints "an ack-ack"
```

```
Print ReplaceString("A", "an Ack-Ack", "a", 1, 1) // prints "an ack-Ack"
Print ReplaceString("", "input", "whatever") // prints "input" (no change)
```

See Also

The **ReplaceStringByKey**, **cmpstr**, **stringmatch**, and **strsearch** functions.

ReplaceStringByKey

ReplaceStringByKey(*keyStr*, *kwListStr*, *newTextStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]]])

The **ReplaceStringByKey** function returns *kwListStr* after replacing the text value of the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use **ReplaceStringByKey** to add or modify text information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found in *kwListStr*, then the key and the value are appended to the end of the returned string.

keySepStr, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

Details

The actual string appended is:

[*listSepStr*] *keyStr* *keySepStr* *newTextStr* *listSepStr*

The optional leading list separator *listSepStr* is added only if *kwListStr* does not already end with a list separator.

keyStr is limited to 255 characters.

kwListStr is searched for an instance of the key string bound by a ";" on the left and a ":" on the right. The text up to the next ";" is replaced by *newTextStr*.

If *newTextStr* is "", any existing value is deleted, but the key, the key separator, and the list separator are retained. To remove a keyword-value pair, use the **RemoveByKey** function.

kwListStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case-sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

Examples

```
Print ReplaceStringByKey("KY", "KY:a;KZ:c", "b") // prints "KY:b;KZ:c"
Print ReplaceStringByKey("KY", "ky=a;", "b", "=") // prints "ky=b;"
Print ReplaceStringByKey("KY", "KY:a,", "b", ":", ",") // prints "KY:b,"
Print ReplaceStringByKey("ky", "ZZ:a,", "b", ":", ",") // prints "ZZ:a,ky:b,"
Print ReplaceStringByKey("kz", "KZ:a,", "b", ":", ",") // prints "KZ:b,"
Print ReplaceStringByKey("kz", "KZ:a,", "b", ":", ",", 1) // prints "KZ:a,kz:b,"
```

See Also

The **ReplaceString**, **ReplaceNumberByKey**, **NumberByKey**, **StringByKey**, **ItemsInList**, **RemoveByKey**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

ReplaceText

ReplaceText [/W=*winName*/N=*name*] *textStr*

The **ReplaceText** operation replaces the text in the most recently created or changed annotation or in the annotation specified by /W=*winName* and /N=*name*.

Parameters

textStr can contain escape codes to control font, font size and other stylistic variations.

If the annotation is a color scale, this command replaces the text of the color scale's main axis label.

Flags

/N=*name* Replaces the text of the named tag or textbox.

ReplaceWave

/W=winName Replaces text in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

See the **Tag** and **TextBox** operations for details about the *textStr* parameter.

The **ColorScale** operation.

ReplaceWave

ReplaceWave [*/W=winName*] **allinCDF**

ReplaceWave [*/X/W=winName*] **trace=traceName, waveName**

ReplaceWave [*/X/Y/W=winName*] **image=imageName, waveName**

ReplaceWave [*/X/Y/W=winName*] **contour=contourName, waveName**

The ReplaceWave operation replaces waves displayed in a graph with other waves. The waves to be replaced, and the replacement waves are chosen by the flags, the keyword and the wave names on the command line.

Flags

/W=winName Replaces the wave in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/X Replaces the wave defining the X data spacing.

/Y Replaces the wave defining the Y data spacing.

Keywords

allinCDF Searches the current data folder for waves with the same names as waves used in the graph. If found and if the waves are of the correct type, they replace the existing waves. Thus, if you have several data folders with identically-named waves containing data from different experimental runs, you can browse through the runs by moving from one data folder to another, using **ReplaceWave allinCDF** to update the graph.

contour=contourName Replaces the wave supplying the Z data for *contourName*. If */X* or */Y* is used, replaces the wave used to set the X or Y data spacing (if the Z data are in a matrix) or the wave used to supply the X or Y positions if XYZ triplets were specified with three separate waves.

image=imageName Replaces the wave supplying the Z data for *imageName*. If */X* or */Y* is used, replaces the wave used to set the X or Y data spacing.

trace=traceName Replaces the wave associated with *traceName*. With the */X* flag, *waveName* will replace the X wave associated with *traceName*, otherwise it will replace the Y wave. Note that *traceName* is derived from the Y wave name; if you created a graph using **Display jack vs sam**, you would use **ReplaceWave/X trace=jack, newsam** to replace the X wave.

Details

Waves are replaced in the graph specified by */W=winName* otherwise waves are replaced in the top graph.

Updating a contour plot in response to replacing a wave can be time-consuming. If you must replace more than one wave, put all the commands separated by semicolons on a single line. In a macro, use

DelayUpdate to prevent updates between command lines.

When using the *allinCDF* keyword, ReplaceWave cannot find waves buried in dynamic annotation text (for instance, using the `\{ }` syntax in an annotation). ReplaceWave will not replace waves used for error bars, either.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-267.

Examples

Make XY plot, then replace the waves:

```

Make fred=x, sam=log(x)
Display fred vs sam
Make fred2=2*x, sam2=ln(x)
ReplaceWave/X trace=fred, sam2
ReplaceWave trace=fred, fred2           // trace is now named fred2

```

Make contour plot with XYZ triplet waves, then replace the waves. Note the DelayUpdate commands after the first two ReplaceWave commands:

```

Make/N=100 junkx, junky, junkz           // Waves for XYZ triplets
junkx=trunc(x/10)                        // X wave for XYZ triplets
junky=mod(x,10)                          // Y wave for XYZ triplets
junkz=sin(junkx[p])*cos(junky[p])        // Z wave for XYZ triplets
Display; AppendXYZContour junkz vs {junkx, junky} // Make contour plot
Make/O/N=150 junkx2, junky2, junkz2      // Make replacement waves
junkx2=trunc(x/15)
junky2=mod(x,15)
junkz2=sin(junkx2[p])*cos(junky2[p])
ReplaceWave/X contour=junkz, junkx2; DelayUpdate
ReplaceWave/Y contour=junkz, junky2; DelayUpdate
ReplaceWave contour=junkz, junkz2

```

This example is suitable for copying all the lines and pasting into the command line, or for use in a macro. If you are typing on the command line, you would want to put the ReplaceWave commands all on one line:

```

ReplaceWave/X contour=junkz, junkx2; ReplaceWave/Y contour=...

```

Resample

Resample [*flags*] *waveName* [, *waveName*]...

The Resample operation resamples *waveName* by interpolating or up-sampling (set by /UP=*upSample*), lowpass filtering, and decimating or down-sampling (set by /DOWN=*downSample*).

Lowpass filtering is specified with /N and /WINF or with /COEF=*coefsWaveName*.

The sampling frequency (1/DimDelta) of a resampled output wave *waveName* is changed by the ratio of *downSample*/*upSample*. For example, if *upSample*=4 and *downSample*=3, then the final sampling rate is 3/4 of the original value.

Straight interpolation can be accomplished by setting *upSample* to the interpolation factor and *downSample*=1, in which case the sample rate is multiplied by *upSample*. Deltax(*waveName*) will be proportionally smaller.

For decimation only, set *upSample*=1 and *downSample* to the decimation factor. The sample rate is divided by *downSample*, and deltax(*waveName*) will be proportionally larger.

Use **RatioFromNumber** to choose appropriate values for *upSample* and *downSample*, or use /SAME=*sWaveName* or /RATE=*sampRate*. See **Resampling Rates Example** for details.

When using /COEF=*coefsWaveName*, the filter coefficients should implement a low-pass filter appropriate for the *upSample* and *downSample* values or aliasing (filtering errors) will result. See **Advanced Externally-Supplied Low Pass Filter Example** for details.

Resampling Rates Flags

The *upSample* and *downSample* values define how much interpolation and decimation to perform. They can be set directly with /UP and /DOWN or indirectly with /SAME or /RATE

/DOWN=*downSample*

Down-samples or decimates the filtered result by this integer factor after up-sampling and lowpass filtering. The default is 1 (no down-sampling).

For example, /DOWN=3 places only every third value in the output wave.

Down-sampling divides the sampling rate of the filtered data by a factor of *downSample*. The DimDelta(*waveName*, *dim*) value is multiplied by the same factor.

/RATE=*sampRate*

Converts the output *waveName* to the specified sampling rate frequency (normally Hz).

The necessary *upSample* and *downSample* values for each *waveName* are computed internally as if you had executed:

```

RatioFromNumber (deltax(waveName)*sampRate)
upSample = V_numerator
downSample = V_denominator

```

/RATE returns V_numerator and V_denominator set to these automatically-determined values for the last *waveName*.

/SAME=*sWaveName*

Converts the output *waveName* to the same sampling rate as *sWaveName*, $1/\text{DimDelta}(\text{sWaveName}, \text{dim})$. The necessary *upSample* and *downSample* values are computed internally as if you had executed:

```
Variable dd = DimDelta(waveName, dim)
RatioFromNumber dd/DimDelta(sWaveName, dim)
upSample = V_numerator
downSample = V_denominator
```

/SAME returns V_numerator and V_denominator set to these automatically-determined values for the last *waveName*.

/UP=*upSample*

Up-samples or interpolates the input by this integer factor. The default is 1 (no up-sampling).

For example, /UP=4 inserts three extra points between each input point (producing 4 times as many values) before the lowpass filtering and down-sampling occurs.

Up-sampling multiplies the sampling rate of the input data by a factor of *upSample*, though no additional signal information is created. The $\text{DimDelta}(\text{waveName}, \text{dim})$ value is divided by the same factor.

Internal Sinc Reconstruction Filter Flags

If /COEF=*coefsWaveName* is not specified, Resample computes a windowed sinc filter from /N, /UP, and /WINF flag values.

If /COEF=*coefsWaveName* is specified, then *coefsWaveName* supplies the filter, and /N and /WINF are ignored. See **Externally-Supplied Low Pass Filter Flags**.

/COEF

Replaces the first *waveName* with coefficients generated by *upSample*, *numReconstructionSamples*, and *windowKindName*, a windowed sinc impulse response.

When resampling multiple *waveNames* with different filters (because /RATE or /SAME were specified and the multiple *waveNames* had different sampling rates), the filter used to resample the last *waveName* is returned.

/N=*numReconstructionSamples*

Specifies the number of input values used to create the up-sampled values (default is 21).

If even, *numReconstructionSamples* is rounded up to the next odd value.

The size of the computed filter is

$(\text{numReconstructionSamples}-1) * \text{upSample} + 1$.

Bigger is better: 15 is usually on the low side for yielding reasonably accurate results, and although 101 will nearly always give very good results, it will be slow.

Use /COEF to output the impulse response, and the FFT to display the frequency response of the interpolator:

```
Make/O coefs
Resample/COEF/N=someNumber coefs
FFT/OUT=3/DEST=coefs_FFT coefs
Display coefs_FFT
```

Bigger is also slower: the filtering is computed in the time-domain, and execution time is linearly related to

$\text{upSample} / \text{downSample} * \text{numReconstructionSamples}$.

/WINF=*windowKindName*

Applies the window, *windowKindName*, to the computed filter coefficients. If /WINF is omitted, the Hanning window is used. For no coefficient windowing, use /WINF=None, though this is discouraged.

Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when *numReconstructionSamples* is large.

Choices for *windowKindName* are (see the FFT /WINF flag for details):

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

Externally-Supplied Low Pass Filter Flags

/COEF=coefsWaveName

Identifies the wave, *coefsWaveName*, containing filter coefficients that implement a low-pass filter with a cutoff frequency of the lesser of $0.5/upSample$ and $0.5/downSample$, where 0.5 corresponds to the Nyquist frequency of the up-sampled data.

For example, if $upSample=2$, then the filter must contain the classic “half-band” filter, which stops the higher half of the frequencies and passes the lower half. If $upSample=10$, then the filter must pass only the lowest 1/10th of the frequencies.

For $downSample > upSample$, the low-pass filter’s cutoff frequency must be $0.5/downSample$. This prevents the decimation from introducing aliasing to the resampled data.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the “center” coefficient in the middle of the wave.

The length of *coefsWaveName* must be $1+upSample*n$, where n is any even integer.

Note: Instead of using */N=numReconstructionSamples* with */COEF*, *numReconstructionSamples* is computed from $upSample$ and the number of points in *coefsWaveName*:

$numReconstructionSamples = 1 + (\text{numpts}(\text{coefsWaveName}) - 1) / upSample$.

Coefficients are usually symmetrical about the middle point, but this is not enforced.

coefsWaveName must not be a destination *waveName*.

coefsWaveName must be single- or double-precision numeric and one-dimensional.

Data Range Flags

/DIM=d

Specifies the wave dimension to resample.

For $d = 0, 1, \dots$, resampling is along rows, columns, etc.

The default is */DIM=0*, which resamples each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all sound samples at a particular time.

To resample in multiple dimensions, execute the command once for each dimension. For example, use */DIM=0* followed by another command with */DIM=1* to resample a two-dimensional wave in each direction.

/E=endEffect

Determines how to handle the ends of the resampled wave(s) (w) when fabricating missing neighbor values.

endEffect=0: Bounce method. Uses $w[i]$ in place of the missing $w[-i]$ and $w[n-i]$ in place of the missing $w[n+i]$.

endEffect=1: Wrap method. Uses $w[n-i]$ in place of the missing $w[-i]$ and vice versa.

endEffect=2: Zero method (default). Uses 0 for any missing value.

endEffect=3: Fill method. Uses $w[0]$ in place of the missing $w[-i]$ and $w[n]$ in place of the missing $w[n+i]$.

Parameters

waveName may be one-dimensional or two-dimensional waves. Without */DIM*, resampling is done along the row (first) dimension. Each column is resampled as if it were a separate one-dimensional row. This allows multichannel audio to be resampled to another frequency.

If */DIM=1*, then resampling proceeds across all the columns of each row.

If */COEF* is specified without *coefsWaveName*, then the first *waveName* is overwritten by the filter coefficients instead of being resampled.

Details

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length (*/N* or the length of *coefsWaveName*) should be small in comparison to the resampled waves.

Resample

Resample assumes that the middle point of *coefsWaveName* corresponds to the delay=0 point. The “middle” point number = $\text{trunc}(\text{numpts}(\text{coefsWaveName} - 1)/2)$. *coefsWaveName* usually contains the two-sided impulse response of a filter, an odd number of points, and implements a low-pass filter whose cutoff frequency is the lesser of $0.5/\text{upSample}$ and $0.5/\text{downSample}$ (0.5 corresponds to the Nyquist frequency = $1/2$ sampling frequency).

When /COEF creates a coefficients wave it sets the X scale deltax to 1 and alters the leftx value so that the zero-phase (center) coefficient is located at $x=0$.

Simple Examples

Interpolation by factor of 4, default filter:

```
Resample/UP=4 data
```

Decimation by factor of 3, default filter:

```
Resample/DOWN=3 data
```

Match sampling rates, default filter:

```
Resample/SAME=dataAtDesiredRate dataAtWrongRate1, dataAtWrongRate2,...
```

Resample waves to 10 KHz sampling rate:

```
Resample/RATE=10e3 dataAtWrongRate1, dataAtWrongRate2,...
```

Interpolate an image by a factor of 2:

```
Resample/UP=2 image // default is /DIM=0, resample rows
Resample/UP=2/DIM=1 image // resample across columns
```

Note: Interpolating by a factor of two does not produce an image with twice as many rows and columns. The new number of rows = $(\text{original rows} - 1) * \text{upSample} + 1$, and a similar computation applies to columns.

Resampling Rates Example

Suppose we have an audio wave sampled at 44,100 Hz and we wish to resample it to a higher 192,000 Hz frequency.

We can use /RATE= 192000 and let Resample determine the correct values (provided *waveName* has its X scaling set properly to reflect sampling at 44100 Hz), but let's compute *upSample* and *downSample* ourselves.

Because the sampling rate = $1/\text{deltax}(\text{wave})$, we can recast the /SAME formula to RatioFromNumber (*desiredSamplingRate/currentSamplingRate*):

```
RatioFromNumber/V (192000 / 44100)
  V_numerator= 640; V_denominator= 147;
  ratio= 4.3537414965986;
  V_difference= 0;
```

Then *upSample*=640 and *downSample*=147.

The 44100 Hz input data will be interpolated by 640 to 28,224,000 Hz.

The result is low-pass filtered with a “cutoff frequency” of $1/640$ th of the interpolated Nyquist frequency = $(28224000/2)/640 = 22,050$ Hz, the same as the input signal's original Nyquist frequency.

The result will be decimated by 147 to 192,000 Hz, which is the desired output sampling frequency.

Note: If *downSample* had been greater than *upSample*, then the low-pass filter's cutoff frequency would have been $1/\text{downSample}$ th of the interpolated Nyquist frequency = $(28224000/2)/\text{downSample}$. This prevents the decimation from introducing aliasing to the resampled data.

```
Resample/UP=640/DOWN=147 sound // convert 44.1 KHz to 192 KHz
```

Advanced Externally-Supplied Low Pass Filter Example

You can generate an appropriate filter by executing commands like these:

```
// Compute a filter for after the input is upsampled
// to restore the frequency content to the original range.
Variable fc = min(0.5 / upSample, 0.5 * upSample / downSample)
// Transition width, small widths need big n
Variable tw= fc/10
// Set end of pass band
Variable f1= fc-tw/2
// Set start of stop band
Variable f2= fc+tw/2
// Use bigger values of n to make the filter smoother
```

```

Variable nReconstruct= 31
Variable n= (nReconstruct-1)*upSample+1           // odd = no phase shift
// Create a wave to hold the coefficients; it gets resized to n
Make/O/N=0 coefsWaveName
FilterFIR/COEF/LO={f1,f2,n} coefsWaveName

```

However, FilterFIR does not create windowed sinc lowpass filters that have the endearing property that the original input values are unaltered in the filtered output, though only if *upSample* > *downSample*. This is called a “Nyquist filter” or “Kth-band filter” in the literature.

If *upSample* > *downSample*, you can enforce the Nyquist criterion by “zeroizing” the designed filter by setting every *upSample*th value to 0 except the center one.

```

// coefsWaveName length must be 1+upSample*n, where n is any even integer

```

```

Function Zeroize(w, upSample)
    Wave w           // coefsWaveName
    Variable upSample // upSample value

    Variable n= DimSize(w,0)
    Variable centerP= floor((n-1)/2) // if n=101, centerP= 50
    Variable i
    for (i=0; i<n; i+=upSample)
        if( i != centerP )
            w[i] = 0
        endif
    endfor
End

```

Resample zeroizes the internally-generated low pass filter when *upSample* > *downSample*.

Additionally, the FilterFIR command generates a low-pass filter whose gain needs to be multiplied by *upsample*:

```
coefsWaveName *= upSample
```

When designing an externally supplied filter, you should also consider the filter’s “polyphase” nature; *coefsWaveName* is actually a set of *upSample* interleaved filters, each with its own response. It makes sense to adjust these filters to produce consistent responses. If you don’t, the results will contain ringing with a period of *upSample* / *downSample*. This is most apparent when *downSample* is 1.

Using the filter we’ve designed so far with *upSample*=4, here’s the output of a constant-input wave:

```

Make/O constantData= 1
Resample/COEF=coefsWaveName/UP=4 constantData

```

The graph shows that the filter response at 0 Hz for the first of 4 filters is 1.0010, the second and fourth filter’s responses are very close to 1.0, and the third filter’s response at 0 Hz is a little less than 1.0.

These variations can be eliminated by normalizing the sum of each polyphase filter to 1.0:

```

Function PolyphaseNormalize(w, upSample)
    Wave w           // coefsWaveName
    Variable upSample // upSample value

    Variable n= DimSize(w,0)
    Variable filt
    // for each filter (0..upSample-1)
    for (filt=0; filt<upSample; filt+=1)
        Variable total=0
        Variable pt
        // compute total for this filter
        for (pt=filt; pt<n; pt+=upSample)
            total += w[pt]
        endfor
        // divide by total to normalize total to 1
    endfor
End

```

ResumeUpdate

Now the filter is ready to be used to filter data:

```
Resample/COEF=coefsWaveName/UP=(upSample)/DOWN=(downSample) dataWave
```

You can see that designing an externally-supplied lowpass filter is much more complicated than using the internal sinc reconstruction filter, which does all this zeroizing, scaling, and polyphase normalization for you.

ResumeUpdate

ResumeUpdate

The **ResumeUpdate** operation cancels the corresponding **PauseUpdate**.

This operation is of use in macros. It is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the **DoUpdate** operation.

See Also

The **DelayUpdate**, **DoUpdate**, and **PauseUpdate** operations.

return

return [expression]

The return flow control keyword immediately stops execution of the current procedure. If called by another procedure, it returns *expression* and control to the calling procedure.

Functions can return only a single value directly to the calling procedure with a return statement. The return value must be compatible with the function type. A function may contain any number of return statements; only the first one encountered during procedure execution is evaluated.

A macro has no return value, so return simply quits the macro.

See Also

The **Return Statement** on page IV-30.

Reverse

Reverse [*type flags*] [/DIM=*d* /P] *waveA* [/D = *destWaveA*] [, *waveB* [/D = *destWaveB*] [, ...]]

The **Reverse** operation reverses data in a wave in a specified dimension. **Reverse** does not accept text waves.

Flags

/DIM = *d* Specifies the wave dimension to reverse.

$d=-1$: Treats entire wave as 1D (default).
 For $d=0, 1, \dots$, operates along rows, columns, etc.
 /P Suppresses adjustment of dimension scaling. Without /P the scaled dimension value of reversed points remains the same.

Type Flags *(used only in functions)*

Reverse also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it is needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-54 and **WAVE Reference Type Flags** on page IV-55 for a complete list of type flags and further details.

Wave Parameters

Note: All wave parameters must follow *wave* in the command. All wave parameter flags and type flags must appear immediately after the operation name (Reverse).

/D=*destWave* Specifies the name of the wave to hold the reversed data. It creates *destWave* if it does not already exist or overwrites it if it exists.

Details

If the optional /D = *destWave* flag is omitted, then the wave is reversed in place.

See Also

The **Sort** operation and **Sorting** on page III-132.

rightx

rightx(*waveName*)

The rightx function returns the X value corresponding to point N of the named 1D wave of length N.

Details

Note that the point numbers in a wave run from 0 to N-1 so there is no point with this X value. To get the X value of the last point in a wave (point N-1), use the following:

```
pnt2x(waveName, numpnts(waveName)-1) // N = numpnts(waveName)
```

which is more accurate than:

```
rightx(waveName) - deltax(waveName)
```

The rightx function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details. The equivalent information for any dimension can be calculated this way:

$$IndexN = DimSize(wave, dim) * DimDelta(wave, dim) + DimOffset(wave, dim)$$

Here *IndexN* is the value of the scaled dimension index corresponding to element N of the dimension *dim* in a wave named *wave* that has N elements in that dimension.

See Also

The **deltax** and **leftx** functions, also the **pnt2x** and **numpnts** functions.

For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-70.

For multidimensional waves, see **DimDelta**, **DimOffset**, and **DimSize**.

root

```
root [ :dataFolderName [ :dataFolderName [ :... ] ] [ :objectName ]
```

Igor's data folder hierarchy starts with the root folder as its basis. The root data folder always exists and it contains all other objects (waves, variables, strings, and data folders). By default, the root data folder is the current data folder in a new experiment. In commands, root is used as part of a path specifying the location of a data object in the folder hierarchy.

See Also

Chapter II-8, **Data Folders**.

Rotate

Rotate *rotPoints*, *waveName* [, *waveName*]...

The Rotate operation rotates the Y values of waves in wavelist by *rotPoints* points.

Parameters

If *rotPoints* is positive then values are rotated from the start of the wave toward the end and *rotPoints* values from the end of a wave wrap around to the start of the wave.

If *rotPoints* is negative then values are rotated from the end of the wave toward the start and *rotPoints* values from the start of a wave wrap around to the end of the wave.

Details

The X scaling of the named waves is changed so that the X values for the Y values remains the same except for the points that wrap around.

The Rotate operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

The shift parameter of the **WaveTransform** operation.

round

round (*num*)

The round function returns the integer value closest to *num*.

The rounding method is “away from zero”.

See Also

The **ceil**, **floor**, and **trunc** functions.

rtGlobals

#pragma rtGlobals = 0, 1, or 2

#pragma rtglobals=1 is a compiler directive that creates global variables at runtime; not at compile time. This line must not be indented. **#pragma rtglobals=0** turns off runtime creation of globals.

If you create procedure files for use by others and you want to use the new logic operations such as **||** that require that **Silent 101** be in effect, then you should use

#pragma rtGlobals=2

in place of the normal **rtGlobals=1**.

See Also

The **Silent** operation and **#pragma**. See **The rtGlobals Pragma** on page IV-39.

S

s

The **s** function returns the current chunk index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled chunk index is available as the **t** function.

Details

Unlike **p**, outside of a wave assignment statement, **s** does not act like a normal variable.

See Also

Waveform Arithmetic and Assignments on page II-80.

For other dimensions, the **p**, **r**, and **q** functions.

For scaled dimension indices, the **x**, **y**, **z** and **t** functions.

Save

Save [*flags*] *waveList* [**as** *fileNameStr*]

The Save operation saves the named waves to disk.

Parameters

waveList is either a list of wave names or, if the /B flag is present, a string list of references to waves. For example, the following commands are equivalent, assuming that the waves in question are in the root data folder and root is the current data folder:

```
Save/J wave0,wave1 as "Test.dat"
Save/J root:wave0,root:wave1 as "Test.dat"
Save/J/B "wave0;wave1;" as "Test.dat"
Save/J/B "root:wave0;root:wave1;" as "Test.dat"
String list="root:wave0;root:wave1;"; Save/J/B list as "Test.dat"
```

The form using the /B flag and a string containing a list of references to waves saves a very large number of waves using one command. This is not possible using a list of wave names because of the 400 character limit in a command. When using this form, the string must contain semicolon-separated wave names or data folder paths leading to waves. Liberal names in the string may be quoted or unquoted.

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If it cannot determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/A[= <i>a</i>]	Appends to the file rather than overwriting it (with /T, /G or /J). <i>a</i> =0: Does not append. <i>a</i> =1: Appends to the file with a blank line before the appended data (same as /A only). <i>a</i> =2: Appends to the file with no blank line before the appended data.
/B	The <i>waveList</i> parameter is a string containing a list of references to waves instead of a literal list of waves.
/C	Saves a copy of the wave when saving as Igor binary.
/DSYM= <i>dsStr</i>	Specifies a string containing the character to use as the decimal symbol for all numbers (default is a period). If <i>dsStr</i> is empty (" "), then the decimal symbol is as defined in system preferences.
/E= <i>useEscapeCodes</i>	Determines whether to use escape sequences for special characters. /E=1: Converts carriage-return, linefeed, tab, and backslash characters to escape sequences when writing general or delimited text files (default; same as no /E). /E=0: No escape sequences used in general or delimited text files. When saving text waves containing backslashes (such as Windows paths) in a file intended for another program, you probably should use /E=0.
/F	Writes delimited and general text files with numeric formatting as it appears in the top table. Has no effect if there is no top table or if the wave being saved does not appear in the top table.
/G	Saves waves in general text format.
/I	presents a dialog from which you can specify file name and folder.
/J	Saves waves in tab-delimited text format.
/M= <i>termStr</i>	Specifies the terminator character or characters to use at the end of each line of text. The default is /M="\r", which uses a carriage return character. This is the Macintosh convention. To use the Windows convention, carriage return plus linefeed, specify /M="\r\n". To use the Unix convention, just a linefeed, specify /M="\n".
/O	Overwrites file if it exists already.
/P= <i>pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
/T	Saves waves in Igor Text format.

/U={writeRowLabels, rowPositionAction, writeColLabels, colPositionAction}

These parameters affect the saving of a matrix (2D wave) to a delimited text (/J) or general text (/G) file. They are accepted no matter what the save type is but are ignored when they don't apply.

If *writeRowLabels* is nonzero, Save writes the row labels of the matrix as the first column of data in the file.

rowPositionAction has one of the following values:

- 0: Don't write a row position column.
- 1: Writes a row position column based on the row scaling of the matrix wave.
- 2: Writes a row position column based on the contents of the row position wave for the matrix. The row position wave is an optional 1D wave whose name is the same as the matrix wave but with the suffix "_RP".

writeColumnLabels and *columnPositionAction* have analogous meanings. The suffix used for the column position wave is "_CP".

See Chapter II-9, **Importing and Exporting Data**, for further details.

/W

Saves wave names (with /G or /J).

Details

The Save operation saves only the named waves; it does not save the entire experiment.

Waves saved in Igor binary format are saved one wave per file. If you are saving more than one wave, you must not specify a *fileNameStr*. Save will give each file a name which consists of the wave name concatenated with ".ibw".

In a general text file (/G), waves with different numbers of points are saved in different groups. Waves with different precisions and number types are saved in same group if they have the same number of points.

In a tab-delimited text file (/J), all waves are saved in one group whether or not they have the same number of points.

If you save multiple 2D waves, the blocks of data are written one after the other.

If you save 3D waves, the data for each wave is written as a contiguous block having as many columns as there are columns in the wave, and R*L rows, where R is the number of rows in the multidimensional wave and L is the number of layers. All rows for layer 0 are saved followed by all rows for layer 1, and so on.

If you save 4D waves, the data for each wave is written as a contiguous block having R*L*C rows, where R is the number of rows, L is the number of layers and C is the number of chunks. Igor writes all data for chunk 0 followed by all data for chunk 1, and so on.

The Save operation will always present a save dialog if you try to save to an existing file without using the overwrite flag.

Here are some details about saving an Igor binary file.

If you omit the path or the file name, the Save operation will normally present a save dialog. However, if the wave has already been saved to a stand-alone file and if you use the overwrite flag, it will save the wave to the same file without a dialog. Also, if the wave has never been saved and the current experiment is an unpacked experiment, it will save to the home folder without a dialog.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

Examples

This function uses the string list of references to waves to save some or all of the waves in the current data folder:

```
Function SaveWavesFromCurrentDF(matchStr)
    String matchStr                // As for the WaveList function.
    String list
    list = WaveList(matchStr, ";", "")
    Save/O/J/W/I/B list
End
```

For example, to save all of the waves in the current data folder, execute:

```
SaveWavesFromCurrentDF("*")
```

To save those waves in the current data folder whose name starts with "wave", execute:

```
SaveWavesFromCurrentDF("wave*")
```

This function saves all of the waves used in a particular graph:

```
Function SaveWavesFromGraph(graphName)           // Saves all waves in graph.
String graphName                                // "" for top graph.
String list, traceList, traceName
Variable index = 0
list = ""
traceList = TraceNameList(graphName, ";", 1)
do
    traceName = StringFromList(index, traceList, ";")
    if (strlen(traceName) == 0)
        break
    endif
    Wave w = TraceNameToWaveRef(graphName, traceName)
    list += GetWavesDataFolder(w,2) + ";"
    index += 1
while(1)
if (strlen(list) > 0)
    Save/O/J/W/I/B list
endif
End
```

See Also

Saving Waves on page II-157.

SaveData

SaveData [*flags*] *fileOrFolderNameStr*

The SaveData operation writes data from the current data folder of the current experiment to a packed experiment file on disk or to a file system folder. “Data” means Igor waves, numeric and string variables, and data folders containing them. The data is written as a packed experiment file or as unpacked Igor binary files in a file-system folder.

Warning: If you make a mistake using SaveData, it is possible to overwrite critical data, even entire folders containing critical data. It is your responsibility to make sure that any file or folder that you can not afford to lose is backed up. If you provide procedures for use by other people, you should warn them as well.

SaveData provides a way to save data for archival storage or unload data from memory during a lengthy process like data acquisition. The file or files that SaveData writes are disassociated from the current experiment.

Use SaveData to save experiment data using Igor procedures. To save experiment data interactively, use the Save Copy button in the Data Browser (Data menu).

Parameters

fileOrFolderNameStr specifies the packed experiment file (if /D is omitted) or the file system folder (if /D is present) in which the data is to be saved. The documentation below refers to this file or folder as the “target”.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If *fileOrFolderNameStr* is omitted or is empty (" "), SaveData displays a dialog from which you can select the target. You also get a dialog if the target is not fully specified by *fileOrFolderNameStr* or the /P=*pathName* flag.

Flags

/D [=d]	Writes to a file-system folder (a directory). If omitted, SaveData writes to an Igor packed experiment file.
d=1	If the target folder already exists, the new data is “mixed-in” with the data already there (same as /D).
d=2	If the target folder already exists, it is completely deleted before the writing of data starts.
	If in doubt, use /D=1. See Details below.
/I	Presents a dialog in which you can interactively choose the target.
/J= <i>objectNamesStr</i>	Saves only the objects named in the semicolon-separated list of object names. See Details below.

/L=saveFlags

Controls what kind of data objects are saved with a bit for each data type:

<i>saveFlags</i>	Bit Number	Saves this Type of Object
1	0	Waves
2	1	Numeric variables
4	2	String variables

To save multiple data types, sum the values shown in the *saveFlags* column. For example, */L=1* saves waves only, */L=2* saves numeric variables only and */L=3* saves both waves and numeric variables.

If */L* is not specified, all of these object types are saved. This is equivalent to */L=7*. All other bits are reserved and must be set to zero. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

/M=modDateTime

Saves waves modified on or after the specified modification date/time. Waves modified before *modDateTime* will not be saved. Applies to waves only (not variables or strings).

modDateTime is in standard Igor time format — seconds since 1/1/1904. If *modDateTime* is zero, all waves will be saved, as if there were no */M* flag at all.

/O

Overwrites existing files or folders on disk.

Warning: If you use the */O* flag and if the target already exists, it will be overwritten without any warning. If you use */O* with */D=2*, **you will completely overwrite the target folder and all of its contents, including subfolders**. Do not use */O* with */D* unless you are absolutely sure you know what you are doing.

/P=pathName

Specifies the folder in which to save the specified file or folder.

pathName is the name of an Igor symbolic path, created via *NewPath*. It is not a file system path like "hd:Folder1:" or "C:\Folder1\". See **Symbolic Paths** on page II-30 for details.

When used with the */D* flag, if */P=pathName* is present and *fileOrFolderNameStr* is ":", the target is the directory specified by */P=pathName*.

/Q

Suppresses normal messages in the history area.

/R

Recursively saves subdata folders.

/T [=topLevelName]

Creates an enclosing data folder in the target with the specified name, *topLevelName*, and writes the data to the new data folder.

If just */T* is specified, it creates an enclosing data folder in the target using the name of the data folder being saved. However, if the data folder being saved is the root data folder, the name *Data* is used instead of *root*. In packed experiment files and unpacked experiment folders, the root data folder is implicit.

If */T* is omitted, the contents of the current data folder are saved with no enclosing data folder.

Details

If */J=objectNamesStr* is used, then only the objects named in *objectNamesStr* are saved. For example, specifying */J="wave0;wave1;"* will save only the two named waves, ignoring any other data in all data folders.

The list of object names used with */J* must be semicolon-separated. A semicolon after the last object name in the list is optional. The object names must not be quoted even if they are liberal. The list is limited to 1000 characters.

Using */J=""* acts like no */J* at all.

The */M=modDateTime* flag can be used in data acquisition projects to save only those waves modified since the previous save. For example, assume that we have a global variable in the root data folder named *gLastWaveSaveDateTime*. Then this function will write out only those waves modified since the previous save:

```
Function SaveModifiedWaves(savePath)
    String savePath          // Symbolic path pointing to output directory
    NVAR lastSave = root:gLastWaveSaveDateTime
    SaveData/O/P=$savePath/D=1/L=1/M=(lastSave) ":"
    lastSave = datetime
End
```

Because the datetime function and the wave modification date have a coarse resolution (one second), this function may sometimes save the same wave twice.

The /M flag makes sense only in conjunction with the /D=1 flag because /D=1 is the only way to mix-in new data with existing data.

Writing to a Packed Experiment File

When writing to a packed file, SaveData creates a standard packed Igor experiment file which you can open as an experiment, browse using the Data Browser, or access using the **LoadData** operation.

If you do not use the /O (overwrite) flag and the packed file already exists on disk, SaveData will present a dialog to confirm which file you want to write to. If you use the /O flag, SaveData will overwrite without presenting a dialog. When writing a packed file, SaveData always completely overwrites the preexisting packed file.

Appending to a packed experiment file is not supported because dealing with the possibility of name conflicts (e.g., two waves with the same name in the same data folder in the packed experiment file) would be technically difficult, very slow and errors would result in corrupted files.

Writing to a File-System Folder

When saving to a folder on disk, SaveData writes wave files, variables files, and subfolders. This resembles the experiment folder of an unpacked experiment, but it does not contain other unpacked experiment files, such as history or procedures. You can browse the folder using the Data Browser or access it using the **LoadData** operation.

If the target directory does not exist, SaveData creates it.

If you do not use the /O (overwrite) flag and the target folder already exists on disk, SaveData will present a dialog to confirm that you want to write to it. SaveData checks for the existence of the top file system folder only. For example, if you write data to hd:Data:Run1, SaveData will display a dialog if hd:Data:Run1 exists. But SaveData will not display a dialog for any folders inside hd:Data:Run1.

If you use the /O flag, SaveData will write without presenting a dialog.

When writing to a directory, SaveData can operate in one of two modes. If you use /D=1 or just /D, SaveData operates in “mix-in” mode. If you use /D=2, SaveData operates in “delete” mode.

Warning: If the target directory exists and delete mode is used, SaveData deletes the target directory and all of its contents. Then SaveData creates the target directory and writes the data to it. This is a complete overwrite operation.

If the target directory exists and mix-in mode is used, SaveData does not do any explicit deletion. It writes data to the target directory and any subdirectories. Conflicting files in any directory are overwritten but other files are left intact.

To prevent you from inadvertently deleting an entire volume, SaveData will not permit you to target the root directory of any volume. You must target a subdirectory.

The /J flag will not work as expected when writing numeric and string variables in mix-in mode. Instead of mixing-in the specified variables, SaveData will overwrite all variables already in the target. This is because all numeric and string variables in a particular data folder are stored in a single file-system folder (named “variables”), so it is not possible to mix-in. Since waves are written one-to-a-file, /J will work as expected for waves.

When SaveData writes a wave to a file-system folder, the file name for the wave is the same as the wave name, with the extension “.ibw” added. This is true even if the wave in the experiment was loaded from a file with a different name. If appending the extension would make the file name too long, it is not appended. Igor limits file names to 31 characters on Macintosh and 255 characters on Windows.

Outputs

SaveData sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel during an interactive save. This would occur if you use the /I flag or if you omit /O and the target already exists. V_flag will also be nonzero if an error occurs during the save.

SaveData sets the string variable S_path to the full file system path to the file or folder that was written. S_path uses Macintosh path syntax (e.g., “hd:FolderA:FolderB:”), even on Windows. When saving unpacked, S_path includes a trailing colon.

Examples

Write the contents of the current data folder and all subdata folders to a packed experiment file:

SaveExperiment

```
Function SaveDataInPackedFile(pathName, fileName)
    String pathName          // Name of symbolic path
    String fileName          // Name of packed file to be written
    SaveData/R/P=$pathName fileName
End
```

Write the contents of the current data folder and all subdata folders to an unpacked file-system folder:

```
Function SaveDataInUnpackedFolder(pathName, folderName)
    String pathName          // Name of symbolic path
    String folderName        // Name of file-system folder
    SaveData/D=1/R/P=$pathName folderName
End
```

Copy the contents of an unpacked file-system folder to a packed experiment file:

```
Function TransferUnpackedToPacked(path1, folderName, path2, fileName)
    String path1             // Points to parent of unpacked folder
    String folderName        // Name of folder containing unpacked data
    String path2             // Points to folder where file is to be written
    String fileName          // Name of packed file to be written
    String savedDF = GetDataFolder(1)
    NewDataFolder/O/S :TempTransfer
    // Load all data from the unpacked folder.
    LoadData/D/Q/R/P=$path1 folderName
    // Save all data to the packed file.
    SaveData/R/P=$path2 fileName
    KillDataFolder :         // Kill TempTransfer
    SetDataFolder savedDF
End
```

SaveExperiment

SaveExperiment [/C/P=*pathName*] [as *fileName*]

The SaveExperiment operation saves the current experiment.

Parameters

The optional *fileName* string contains the name of the experiment to be saved. *fileName* can be the currently open experiment, in which case it overwrites the experiment file.

If *fileName* and *pathName* are omitted and the experiment is Untitled, you will need to locate where the experiment file will be saved interactively via a dialog.

If you use a full or partial path for *pathName*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/C	Saves an experiment copy (valid only when <i>fileName</i> or <i>pathName</i> is provided or both if experiment is Untitled).
/P= <i>pathName</i>	Specifies folder in which to save the experiment. <i>pathName</i> is the name of an existing symbolic path.

Details

SaveExperiment acts like the Save menu command in the File menu. If the experiment is associated with an already saved file, then SaveExperiment with no parameters will simply save the current experiment. If the experiment resides only in memory and has not yet been saved, then a dialog will be presented unless the path and file name are specified.

If you use a full path in the name you will not need the /P flag. If instead you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

SaveGraphCopy

SaveGraphCopy [*flags*][*as fileNameStr*]

The SaveGraphCopy operation saves a graph and its waves in an Igor packed experiment file.

Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/I	Presents a dialog from which you can specify file name and folder.
/O	Overwrites file if it exists already.
/P= <i>pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
/W= <i>winName</i>	<i>winName</i> is the name of the graph to be saved. If /W is omitted or if <i>winName</i> is " ", the top graph is saved.
/Z	Errors are not fatal and error dialogs are suppressed. See Details.

Details

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-27). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the “top” data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.

SaveGraphCopy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that SaveGraphCopy will not save. Second, controls typically rely on procedures which are not saved by SaveGraphCopy.

SaveGraphCopy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave1 which is not in the graph, SaveGraphCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

SaveGraphCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveGraphCopy.

The **SaveData** operation also has the ability to save a graph to a packed experiment file. SaveData is more complex but a bit more flexible than SaveGraphCopy.

Examples

This function saves all graphs in the experiment to individual packed experiment files.

```
Function SaveAllGraphsToPackedFiles(pathName)
    String pathName          // Name of an Igor symbolic path.
    String graphName
    Variable index
    index = 0
    do
        graphName = WinName(index, 1)
        if (strlen(graphName) == 0)
            break
        endif
        String fileName
        sprintf fileName, "%s.pxp", graphName
        SaveGraphCopy/P=$pathName/W=$graphName as fileName
        index += 1
    while(1)
End
```

See Also

SaveTableCopy and SaveData operations; Merging Experiments on page II-27.

SaveNotebook

SaveNotebook [*flags*] *notebookName* [*as fileNameStr*]

The SaveNotebook operation saves the named notebook.

Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

/H={encodingName, writeParagraphProperties, writeCharacterProperties, PNGOrJPEG, quality, bitDepth}
Controls the creation of an HTML file.

encodingName

Specifies the HTML file encoding. The recommended value for most purposes is "UTF-8". See **Details** for more information.

writeParagraphProperties

Determines what paragraph properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

Bit 0: Write paragraph alignment.

Bit 1: Write first indent.

Bit 2: Write minimum line spacing.

Bit 3: Write space-before and space-after paragraph.

All other bits are reserved for future use and should be set to zero.

writeCharacterProperties

Determines what character properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

Bit 0: Write font families.

Bit 1: Write font sizes.

Bit 2: Write font styles.

Bit 3: Write text colors.

Bit 4: Write text vertical offsets.

All other bits are reserved for future use and should be set to zero.

If you set bit 2, SaveNotebook exports only the bold, underline, and italic styles because other character styles are not supported by HTML.

PNGOrJPEG

Determines whether SaveNotebook will write picture files as PNG or JPEG:

0: PNG (default).

1: JPEG.

2: JPEG.

Prior to Igor Pro 5, *PNGOrJPEG*=2 wrote as JPEG if QuickTime JPEG support was available or as PNG otherwise. As of Igor Pro 5, which has built-in JPEG support, both *PNGOrJPEG*=2 and *PNGOrJPEG*=1 write as JPEG. For both codes, QuickTime is used if it is available because it supports the quality and depth parameters although built-in JPEG support currently always uses *quality*=0.9.

See **Details** for more on HTML picture files.

The next two parameters, *quality*, and *bitDepth*, are used only when writing JPEG files using QuickTime.

<i>quality</i>	Specifies the degree of compression or image quality when writing pictures as JPEG files. It is a value from 1.0 (default) to 0.0, with 1.0 giving the greatest quality but largest file size and 0.0 giving the least quality but smallest file size. Use the highest quality that gives an acceptable file size. Often this will be 1.0.
<i>bitDepth</i>	Specifies the color depth when writing pictures as JPEG files. It specifies the desired bit depth of the picture. Only the following values are legal: 1, 8 (default), 16, 24, 32. For most Web use, 8 is fine. As of QuickTime 4, QuickTime ignores this parameter.
/I	Saves interactively. A dialog is displayed.
/M= <i>messageStr</i>	Specifies prompt message used in save dialog.
/O	Overwrites existing file without asking permission.
/P= <i>pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
/S= <i>saveType</i>	1: Normal save (default). 2: Save-as. 3: Save-a-copy. 4: Export as RTF (Rich Text Format). 5: Export as HTML (Hypertext Markup Language). 6: Export as plain text. 7: Export as formatted notebook.

Details

Interactive (/I) means that Igor displays the Save, Save As, or Save a Copy dialog.

The save will be interactive under the following conditions:

- You include the /I flag and the *saveType* is 2, 3, 4, 5, 6, or 7.
- *saveType* is 2, 3, 4, 5, 6, or 7 and you do not specify the path or filename.

If the *saveType* is normal and the notebook has previously been saved to a file then the /I flag, the path and file name that you specify, if any, are ignored and the notebook is saved to its associated file without user intervention.

The full path to the saved file is stored in the string S_path. If the save was unsuccessful, S_path will be "".

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details.

For background information on writing RTF files, see **Import and Export Via Rich Text Format Files** on page III-21.

For background information on writing HTML files, see **Exporting a Notebook as HTML** on page III-23.

For background information regarding the HTML *encodingName* parameter, see **HTML Character Encoding** on page III-26. This table lists how Igor responds to various values for this parameter:

"UTF-8"	Encodes the document using the UTF-8 encoding which is a kind of packed Unicode. It is good for documents that contain non-Roman text, such as symbols and Asian text. This is the best choice for most documents.
"UTF-2"	Encodes the document using the UTF-2 encoding which is 16-bit Unicode. It is generally not recommended because some browsers don't support it. However, as time goes by, browser support will improve.
"Native"	Writes the document using the native character set of the operating system. On Macintosh, this equates to "mac" (the Mac OS Roman character set). On Windows, it equates to "Windows-1252" (the Windows Western character set). This may give better results than UTF-8 for some documents and with some browsers but you should use it only if you determine that UTF-8 doesn't work for your application.
" "	Writes the document using the native character set of the operating system but omits the Content-Type meta tag.

In addition, you can provide any other string of 63 or fewer bytes. The main use for this is for documents that are primarily in an Asian language. For example, if your document is primarily in Japanese, then the characters in the document are already in the Shift-JIS encoding. You can specify "Shift-JIS" as the

encodingName. This uses "Shift-JIS" in the Content-Type meta tag and to write the text out without any special encoding. The main advantage of this technique over the UTF-8 encoding is that a file written using Shift-JIS can be edited in Igor or other commonly-available text editors while UTF-8 can not.

When creating an HTML file, SaveNotebook can write pictures using the PNG or JPEG graphics formats. PNG support is built into Igor Pro. Built-in JPEG support was added in Igor Pro 5. Previously Igor used QuickTime to write JPEG files. It still does if QuickTime is available but if not, it uses built-in routines. For most applications, the only reason to use JPEG rather than PNG is that some old web browsers do not support PNG.

Chapter III-1, **Notebooks**.

Setting Bit Parameters on page IV-11 for further details about bit settings.

SavePackagePreferences

SavePackagePreferences [*/FLSH=flush* */P=pathName*] *packageName*, *prefsFileName*, *recordID*, *prefsStruct*

The SavePackagePreferences operation saves preference data in the specified structure so that it can be accessed later via by the **LoadPackagePreferences** operation.

The data is stored in memory and by default flushed to disk when the current experiment is saved or closed and when Igor quits.

If the */P* flag is present then the location on disk of the preference file is determined by *pathName* and *prefsFileName*. However in the usual case the */P* flag will be omitted and the preference file is located in a file named *prefsFileName* in a directory named *packageName* in the Packages directory in Igor's preferences directory.

Note: You must choose a very distinctive name for *packageName* as this is the only thing preventing collisions between your package and someone else's package.

See **Saving Package Preferences** on page IV-180 for background information and examples.

Parameters

packageName is the name of your package of Igor procedures. It is limited to 31 characters and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package.

prefsFileName is the name of a preference file to be saved by SavePackagePreferences. It should include an extension, typically ".bin".

prefsStruct is the structure containing the data to be saved in the preference file on disk.

recordID is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordIDs* to identify which structure you want to save. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

Flags

<i>/FLSH=flush</i>	Controls when the data is actually written to the preference file: <ul style="list-style-type: none">0: The data will be flushed to disk when the current experiment is saved, reverted or closed or when Igor quits. This is the default behavior used when <i>/FLSH</i> is omitted and is recommended for most purposes.1: The data is flushed to disk immediately.
<i>/P=pathName</i>	Specifies the directory in which to save the file specified by <i>prefsFileName</i> . <p><i>pathName</i> is the name of an existing symbolic path. See Symbolic Paths on page II-30 for details.</p> <p><i>/P=\$<empty string variable></i> acts as if the <i>/P</i> flag were omitted.</p>

Details

SavePackagePreferences set the variable *V_flag* to 0 if preferences were successfully saved or to a nonzero error code if they were not saved. The latter case is unlikely and would indicate some kind of corruption such as if Igor's preferences directory were deleted.

Example

See the example under **Saving Package Preferences in a Special-Format Binary File** on page IV-181.

See Also
LoadPackagePreferences.

SavePICT

SavePICT [*flags*] [*as fileNameStr*]

The SavePICT operation creates a picture file representing the top graph, table or layout. The picture file can be opened by many word processing, drawing, and page layout programs.

To use any of the QuickTime graphic export formats (/T flag), you will need to have QuickTime 4 or later installed (full install) in your system.

Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

If you omit *fileNameStr* but include /P=*pathName*, SavePICT writes the file using a default file name. The default file name is the window name followed by an extension, such as ".png", ".emf" or ".PICT", that depends on the graphic format being exported.

If you specify the file name as "Clipboard", and do *not* specify a /P=*pathName*, Igor copies the picture to the Clipboard, rather than to a file. QuickTime formats (/T) can not be put on the Clipboard.

If you specify the file name as "_string_" the output will be saved into a string variable named S_Value, which is used with the **ListBox** binary bitmap display mode.

Flags

/B= <i>dpi</i>	Controls image resolution in dots-per-inch (<i>dpi</i>). The legal values for <i>dpi</i> are $n*72$ where <i>n</i> can be from 1 to 8. The actual image <i>dpi</i> is not used. Igor calculates <i>n</i> from your value of <i>dpi</i> and then multiplies <i>n</i> by your computer's screen resolution. This is because bitmap images that are not an integer multiple of the screen resolution look quite bad. The /B flag can be used with QuickTime export types (/T). Also see the /RES flag.
/C= <i>c</i>	Specifies color mode. <i>c</i> =0: Black and white. <i>c</i> =1: RGB color (default). <i>c</i> =2: CMYK color (EPS and native TIFF only).
/D= <i>d</i>	Specifies bit depth for QuickTime image export. <i>d</i> may be 1, 8, 16, 24 (default), or 32 bits. Not all formats use depth. An intermediate picture at the current screen depth is used and may limit the quality.
/E= <i>e</i>	Sets graphics format used when exporting a graphic. See Details for formats. See also Chapter III-5, Exporting Graphics (Macintosh) , or Chapter III-6, Exporting Graphics (Windows) , for a description of these modes and when to use them.
/EF= <i>e</i>	Sets font embedding. <i>e</i> =0: No font embedding. <i>e</i> =1: Embed nonstandard fonts. <i>e</i> =2: Embed all fonts.
/I	Specifies that /W coordinates are inches.
/M	Specifies that /W coordinates are centimeters.
/N= <i>winSpec</i>	Deprecated: Igor Pro 4.09-compatibility version of /WIN.
/O	Overwrites file if it exists.
/P= <i>pathName</i>	Saves file into a folder specified by <i>pathName</i> , which is the name of an existing symbolic path.

/PICT= <i>pict</i>	Saves specified named picture rather than the target window. Native format of the picture is used and all format flags are ignored.
/PLL= <i>p</i>	Specifies Postscript language level when used in conjunction with EPS export. <i>p</i> =1: For very old Postscript printers. <i>p</i> =2: For all other uses (default).
/Q= <i>q</i>	Sets quality factor (0.0 is lowest, 1.0 is highest). Default is dependent on individual format. Used only by lossy formats such as QuickTime JPEG.
/R= <i>resID</i>	Saves the picture in a resource fork with resource ID= <i>resID</i> , where <i>resID</i> is between 1 and 32767. This flag is meaningful on Macintosh only. It is ignored on Windows. Also, it does not work with EPS or PNG graphics.
/RES= <i>dpi</i>	Controls the resolution of image formats in dots-per-inch. Unlike the similar /B flag, the value for /RES is the actual output resolution and is useful when your publisher demands a specific resolution. The /RES flag can be used with QuickTime export types (/T).
/S	Suppresses the preview that is normally included with an EPS file.
/SNAP= <i>s</i>	Saves snapshot of a graph window. <i>s</i> =1: Include all controls in capture. <i>s</i> =2: Capture only window data content. Snapshot mode is available only for graphs and only for bitmap exports as PNG, JPEG, or TIFF at screen resolution. When using /W to specify the size, the capture is sized to fit within the specified rectangle while maintaining the window aspect ratio. Size is in pixels.
/T= <i>t</i>	Specifies a QuickTime export type. An error will be generated if QuickTime is not present or if the desired export type is not available. <i>t</i> is a string containing a 4 character code for the export type. Valid types include "PNGf" for PNG, "TIFF" for TIFF, "JPEG" for JPEG. GIF is "GIFf" but is not currently supported by QuickTime presumably due to the patent situation. This might change in the future if Apple or a third party provides a component for GIF writing.
/TRAN[= <i>1 or 0</i>]	Makes white background areas transparent using an RGBA type PNG when used with native PNG export of graphs or page layouts. In layouts, only embedded graphs and textboxes marked as transparent will be transparent. Nonembedded graphs, pictures, and tables will be opaque. PNG transparency is not honored when placed in Igor.
/W=(<i>left,top,right,bottom</i>)	Specifies the size of the picture when exporting a graph. If /W is omitted, it uses the graph window size. When exporting a page layout, specifies the part of the page to export. Only objects that fall completely within the specified area are exported. If /W is omitted, the area of the layout containing objects is exported. Coordinates for /W are in points unless /I or /M are specified before /W.
/WIN= <i>winSpec</i>	Saves the named window or subwindow. <i>winSpec</i> can be just a window name, or a window name following by a "#" character and the name of the subwindow, as in /WIN=Panel10#G0.
/Z	Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details

SavePICT sets the variable V_flag to 0 if the operation succeeds or to a nonzero error code if it fails.

If you specify a path using the /P=*pathName* flag, then Igor saves the file in the folder identified by the path. Note that *pathName* is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-30 for details. Otherwise, with no path specified, Igor presents a standard save dialog to let you specify where the file is to be saved.

When writing an EPS file, it normally includes a screen preview. On Macintosh, this is a PICT in the resource fork of the file. On Windows, it is a TIFF embedded in the EPS file. Using the /S flag, you can suppress the preview to save disk space, to work around a program that is confused by the preview, or to create a completely platform-neutral file.

On Macintosh, the picture is normally written to the data fork of the file. Most applications read it from the data fork. Some, however, read PICTs from the resource fork. If you use `/R=resID`, it writes the PICT to the resource fork of the file, using `resID` as the resource ID.

Graphics formats, specified via `/E`, are as follows:

<code>/E</code> Value	Macintosh File Format	Windows File Format
-8	PDF file.	PDF file.
-7	TIFF file. Lossless but larger file than PNG; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. You can specify the resolution with the <code>/B</code> or <code>/RES</code> flag. Cross-platform compatible.	
-6	JPEG file. Lossy compression; best used for grayscale and color images with smooth tones. The <code>/Q</code> flag specifies compression quality and the <code>/B</code> or <code>/RES</code> flag sets the resolution. Cross-platform compatible.	
-5	PNG (Portable Network Graphics) file. Lossless compression; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. Specify the resolution with <code>/B</code> or <code>/RES</code> . Cross-platform compatible.	
-4	High resolution bitmap PICT file. Default resolution is 288 dpi. Specify the resolution with <code>/B</code> or <code>/RES</code> .	Device-independent bitmap file (DIB). Default resolution is 4x screen resolution. Specify the resolution with <code>/B</code> or <code>/RES</code> .
-3	Encapsulated PostScript (EPS) file.	Encapsulated PostScript (EPS) file.
-2	High-resolution PICT.	High-resolution enhanced metafile.
-1	Obsolete – Pure PostScript PICT.	Obsolete – PostScript-enhanced metafile.
0	Obsolete – PostScript PICT with QuickDraw text.	Obsolete – PostScript-enhanced metafile.
1	Normal PICT.	Windows metafile at screen resolution (or any multiple of <code>/E ≥ 1</code> resolution).
2	PICT at 2x size.	Windows metafile at 2x size.
4	PICT at 4x size.	Windows metafile at 4x size.
8	PICT at 8x size.	Windows metafile at 8x size.

Note: The Windows metafile format works on graph and table windows but does not work on page layout windows. The PostScript-enhanced metafile format works on graph windows only. If you attempt to use an unsupported format on a table or page layout window, SavePICT will use the enhanced metafile format instead.

See Also

The **ImageSave** operation for saving waves as PICTs and other image file formats. The **LoadPICT** operation.

See Chapter III-5, **Exporting Graphics (Macintosh)**, or Chapter III-6, **Exporting Graphics (Windows)**, for a description of the `/E` modes.

SaveTableCopy

SaveTableCopy [*flags*][*as fileNameStr*]

The SaveTableCopy operation saves a copy of the data displayed in a table on disk. The saved file can be an Igor packed experiment file, a tab-delimited text file, or a comma-separated values text file.

When saving as text, the data format matches the format shown in the table. Keep in mind that this will cause truncation if the underlying data has more precision than shown in the table. The point column is never saved.

Parameters

The file to be written is specified by *fileNameStr* and `/P=pathName` where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor

can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Flags

<i>/A=a</i>	<p>Appends data to the file rather than overwriting.</p> <p><i>a=0:</i> Does not append.</p> <p><i>a=1:</i> Appends to the file with a blank line before the appended data.</p> <p><i>a=2:</i> Appends to the file with no blank line before the appended data.</p> <p><i>/A</i> applies when saving text files and is ignored when saving packed experiment files.</p> <p>If the file does not exist, a new file is created and <i>/A</i> has no effect.</p>
<i>/I</i>	Presents a dialog from which you can specify file name and folder.
<i>/M=termStr</i>	<p>Specifies the terminator character or characters to use at the end of each line of text. The default is <i>/M="\r"</i> on Macintosh and <i>/M="\r\n"</i> on Windows; it is used when <i>/M</i> is omitted. To use the Unix convention, just a linefeed, specify <i>/M="\n"</i>.</p>
<i>/N=n</i>	<p>Specifies whether to use column names, titles, or dimension labels.</p> <p><i>n</i> is a bitwise parameter with the bits defined as follows:</p> <p>Bit 0: Include column names or titles. The column title is included if it is not empty. If it is empty, the column name is included.</p> <p>Bit 1: Include horizontal dimension labels if they are showing in the table.</p> <p>The default setting for <i>n</i> is 1. All other bits are reserved and must be zero.</p>
<i>/O</i>	Overwrites file if it exists already.
<i>/P=pathName</i>	Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.
<i>/S=s</i>	<p>Saves all of the data in the table (<i>s=0</i>; default) or the selection only (<i>s=1</i>).</p> <p><i>/S</i> applies when saving text files and is ignored when saving packed experiment files.</p>
<i>/T=saveType</i>	<p>Specifies the file format of the saved table.</p> <p><i>saveType=0:</i> Packed experiment file.</p> <p><i>saveType=1:</i> Tab-delimited text file.</p> <p><i>saveType=2:</i> Comma-separated values text file.</p> <p><i>saveType=3:</i> Space-delimited values text file.</p>
<i>/W=winName</i>	<i>winName</i> is the name of the table to be saved. If <i>/W</i> is omitted or if <i>winName</i> is "", the top table is saved.
<i>/Z</i>	Errors are not fatal and error dialogs are suppressed. See Details.

Details

The main uses for saving a table as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-27). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the "top" data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.

SaveTableCopy does not know about dependencies. If a table contains a wave, *wave0*, that is dependent on another wave, *wave1* which is not in the table, SaveTableCopy will save *wave0* but not *wave1*. When the saved experiment is open, there will be a broken dependency.

The main use for saving as a tab or comma-delimited text file is for exporting data to another program.

When calling SaveTableCopy from a procedure, you should call DoUpdate before calling SaveTable copy. This insures that the table is up-to-date if your procedure has redimensioned or otherwise changed the number of points in the waves in the table.

SaveTableCopy sets the variable *V_flag* to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the */Z* flag and check *V_flag* after calling SaveTableCopy.

The **SaveData** operation also has the ability to save a table to a packed experiment file. SaveData is more complex but a bit more flexible than SaveTableCopy.

Examples

This function saves all tables to a single tab-delimited text file.

```
Function SaveAllTablesToTextFile(pathName, fileName)
  String pathName          // Name of an Igor symbolic path.
  String fileName

  String tableName
  Variable index
  index = 0
  do
    tableName = WinName(index, 2)
    if (strlen(tableName) == 0)
      break
    endif
    SaveTableCopy/P=$pathName/W=$tableName/T=1/A=1 as fileName
    index += 1
  while(1)
End
```

See Also

SaveGraphCopy and **SaveData** operations; **Merging Experiments** on page II-27.

sawtooth

sawtooth(num)

The sawtooth function returns $((num + n2\pi) \bmod 2\pi) / 2\pi$ where n is used to correct if num is negative. Sawtooth is used to create arbitrary periodic waveforms like sine and cosine.

Examples

```
wave1 = sawtooth(x)
```

creates a sawtooth in wave1 whose Y values range from 0 to 1 as its X values go through 2π units.

```
wave1 = exp(sawtooth(x))
```

creates a series of exponentials in wave1 of amplitude $\exp(1)$ and period 2π .

You can also use sawtooth to create periodic repetitions of a given part of a wave:

```
wave1 = wave2(sawtooth(x))
```

creates a periodic repetition of wave2 in wave1 given the correct X scaling for the waves.

ScreenResolution

ScreenResolution

The ScreenResolution function returns the logical resolution of your video display screen in dots per inch (dpi). On Macintosh this is always 72. On Windows it is usually 96 (small fonts) or 120 (large fonts).

Secs2Date

Secs2Date(seconds, format)

The Secs2Date function returns a string containing a date.

With *format* values 0, 1, and 2, the formatting of dates depends on your operating system and on your preferences entered in the Date & Time control panel (*Macintosh*) or the Regional Settings control panel (*Windows*).

If *format* is -1, the format is independent of the operating system. The fixed-length format is "*day / month / year (dayOfWeekNum)*", where *dayOfWeekNum* is 1 for Sunday, 2 for Monday... and 7 for Saturday.

Parameters

seconds is the number of seconds from 1/1/1904 to the date to be returned.

format is a number between -1 and 2 which specifies how the date is to be constructed.

Examples

```
Print Secs2Date(DateTime,-1)      // prints 15/03/1993 (2)
Print Secs2Date(DateTime,0)      // prints 3/15/93
```

Secs2Time

```
Print Secs2Date(DateTime,1)      // prints Monday, March 15, 1993
Print Secs2Date(DateTime,2)      // prints Mon, Mar 15, 1993
```

See Also

The **date**, **date2secs** and **DateTime** functions.

Secs2Time

Secs2Time(seconds, format, [fracDigits])

The Secs2Time function returns a string containing a time.

Parameters

seconds is the number of seconds from 1/1/1904 to the time to be returned.

format is a number between 0 and 5 that specifies how the time is to be constructed. It is interpreted as follows:

- 0: Normal time, no seconds.
- 1: Normal time, with seconds.
- 2: Military time, no seconds.
- 3: Military time, with seconds and optional fractional seconds.
- 4: Elapsed time, no seconds.
- 5: Elapsed time, with seconds and optional fractional seconds.

“Normal” formats (0 and 1) follow the preferred formatting of the short time format as set in the International control panel (*Macintosh*) or in the Regional and Language Options control panel (*Windows*).

“Military” means that the hour is a number from 0 to 23. Hours greater than 23 are wrapped.

“Elapsed” means that the hour is a number from -9999 to 9999. The result for hours outside that range is undefined.

The *fracDigits* parameter is optional and specifies the number of digits of fractional seconds. The default value is 0. The *fracDigits* parameter is ignored for format=0, 1, 2, and 4.

Examples

```
Print Secs2Time(DateTime,0)      // prints 1:07 PM
Print Secs2Time(DateTime,1)      // prints 1:07:28 PM
Print Secs2Time(DateTime,2)      // prints 13:07
Print Secs2Time(DateTime,3)      // prints 13:07:29
Print Secs2Time(30*60*60+45*60+55,4) // Prints 30:45
Print Secs2Time(30*60*60+45*60+55,5) // Prints 30:45:55
```

See Also

The **date**, **date2secs** and **DateTime** functions. Also, **Operators** on page IV-5 for **?:** details.

SelectNumber

SelectNumber(whichOne, val1, val2 [, val3])

The SelectNumber function returns one of *val1*, *val2*, or (optionally) *val3* based on the value of *whichOne*.

SelectNumber(*whichOne*, *val1*, *val2*) returns *val1* if *whichOne* is zero, else it returns *val2*.

SelectNumber(*whichOne*, *val1*, *val2*, *val3*) returns *val1* if *whichOne* is negative, *val2* if *whichOne* is zero, or *val3* if *whichOne* is positive.

Details

SelectNumber works with complex (or real) *val1*, *val2*, and *val3* when the result is assigned to a complex wave or variable. (Print expects a real result, see the “causes error” example, below).

If *whichOne* is NaN, then NaN is returned.

whichOne must always be a real value.

Unlike the **?:** conditional operator, SelectNumber always evaluates all of the numeric expression parameters *val1*, *val2*, ...

SelectNumber works in a macro, whereas the conditional operator does not.

Examples

```

Print SelectNumber(0,1,2)           // prints 1
Print SelectNumber(0,1,2,3)         // prints 2
wv=SelectNumber(numtype(wv[p])==2,wv[p],0) // replace NaNs with zeros
// chooses among complex values
Variable/C cx= SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
// causes error because Print expects a real value (not complex)
Print SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))
// The real function expects a complex result
Print real(SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1)))

```

See Also

The **SelectString** and **limit** functions, and **Waveform Arithmetic and Assignments** on page II-80. Also, **Operators** on page IV-5 for details about the ?: operator.

SelectString

SelectString(*whichOne*, *str1*, *str2* [, *str3*])

The SelectString function returns one of *str1*, *str2*, or (optionally) *str3* based on the value of *whichOne*.

SelectString(*whichOne*, *str1*, *str2*) returns *str1* if *whichOne* is zero, else it returns *str2*.

SelectString(*whichOne*, *str1*, *str2*, *str3*) returns *str1* if *whichOne* is negative, *str2* if *whichOne* is zero, or *str3* if *whichOne* is positive.

Details

If *whichOne* is NaN, then "" is returned.

whichOne must always be a real value.

Unlike the ?: conditional operator, SelectString always evaluates all of the string expression parameters *str1*, *str2*, ...

SelectString works in a macro, whereas the conditional operator does not.

Examples

```

Print SelectString(0,"hello","there") // prints "hello"
Print SelectString(1,"hello","there") // prints "there"
Print SelectString(-3,"hello","there","jack") // prints "hello"
Print SelectString(0,"hello","there","jack") // prints "there"
Print SelectString(100,"hello","there","jack") // prints "jack"

```

See Also

The **SelectNumber** function and **String Expressions** on page IV-12. Also, **Operators** on page IV-5 for details about the ?: operator.

SetActiveSubwindow

SetActiveSubwindow *subWinName*

The SetActiveSubwindow operation specifies the subwindow that is to be activated. This command is mainly for use by recreation macros.

Parameters

subWinName is the name of an existing subwindow. Use `_endfloat_` for *subWinName* to make a newly-created floating panel not be the default target.

When identifying a subwindow with *subWinName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

SetAxis

SetAxis [*flags*] *axisName* [, *num1*, *num2*]

The SetAxis operation sets the extent (or “range”) of the named axis.

Parameters

axisName is usually “left”, “right”, “top” or “bottom”, but it can also be the name of a free axis, such as “vertCrossing”.

SetBackground

If *axisName* is a vertical axis such as “left” or “right” then *num1* sets the bottom end of the axis and *num2* sets the top end of the axis.

If *axisName* is a horizontal axis such as “top” or “bottom” then *num1* sets the left end of the axis and *num2* sets the right end of the axis.

You can flip the graph by reversing *num1* and *num2* (or by using /A/R). This is particularly useful for images, because Igor plots an image inverted.

Flags

/A[= <i>a</i>]	Autoscale axis (when used, <i>num1</i> , <i>num2</i> should be omitted) <i>a</i> =0: No autoscale. Same as no /A flag. <i>a</i> =1: Normal autoscale. Same as /A. <i>a</i> =2: Autoscale Y axis to a subset of the data defined by the current X axis range.
/E= <i>z</i>	Sets the treatment of zero when the axis is in autoscale mode. <i>z</i> =0: Normal mode where zero is not treated special. <i>z</i> =1: Forces the smaller end of the axis to be set to zero (autoscale from zero). <i>z</i> =2: Axis is symmetric about zero.
/N= <i>n</i>	Sets the algorithm for axis autoscaling. <i>n</i> =0: Normal mode; sets the axis limits equal to the data limits. <i>n</i> =1: Picks nice values for the axis limits. <i>n</i> =2: Picks nice values; also ensures that the data is inset from the axis ends.
/R	Reverses the autoscaled axis (smaller values at the left for horizontal axes, at the top for vertical axes) when used with /A. Although it only has an effect for autoscale, it can be used with nonautoscale version of SetAxis so that the next time the Axis Range tab is used the “reverse axis” checkbox will already be set.
/W= <i>winName</i>	Sets axes in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Z	No error reporting if named axis doesn’t exist in a style macro.

SetBackground

SetBackground *numericExpression*

The SetBackground operation sets *numericExpression* as the background task.

The background task runs while Igor is not busy with other things. Normally, there won’t be a background task. The most common use for the background task is to monitor or drive a continuous data acquisition process.

Parameters

numericExpression is a single precision numeric expression that Igor executes when it isn’t doing anything else.

Details

numericExpression is expected to return one of three numeric values:

- 0: Background task executed normally.
- 1: Background task wants to stop.
- 2: Background task encountered error and wants to stop.

Usually the expression will be a call to a user-defined numeric function or external function to drive or monitor data acquisition. The expression should be designed to execute very quickly and it should not present a dialog to the user nor should it create or destroy windows. Generally, it should do nothing more than store data into waves or variables. You can use Igor’s dependency mechanism to perform more extensive tasks.

SetBackground designates the background task but you must use CtrlBackground to start it. You can also use KillBackground to stop it. You can not call SetBackground from the background function itself.

See Also

The **BackgroundInfo**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Task** on page IV-211.

SetDashPattern

SetDashPattern *dashNumber*, {*d1*, *s1* [, *d2*, *s2*]...}

The SetDashPattern operation defines a dashed-line pattern for a user-defined dashed line. These dashed lines are used by the drawing tools and the Modify Waves Appearance dialog, and are elsewhere referred to as “line styles”.

Parameters

dashNumber specifies which dash pattern is to be set. It must be between 1 and 17. Dash pattern 0 is reserved for a solid line.

0	_____	9	- - - - -
1	10	- - - - -
2	11	- - - - -
3	- - - - -	12	_____
4	13	_____
5	- - - - -	14	_____
6	- - - - -	15	_____
7	- - - - -	16	_____
8	- - - - -	17	_____

{*d1*,*s1* [,*d2*,*s2*]...} defines the dash pattern. The dash pattern consists of 1 to 8 “dash,skip” pairs. Each pair consists of the number of drawn points followed by the number of skipped points.

d1 specifies the number of drawn points and *s1* specifies the number of skipped points in the first “dash,skip” pair. *d2* and *s2* specify the number of drawn and skipped points in the second pair and so on. Each draw or skip value must be between 1 and 127.

Details

SetDashPattern updates *all* graphs, panels and layouts so that any dashed lines will be updated with the new pattern. If you repeatedly call SetDashPattern from within a macro, you should precede the commands with the PauseUpdate operation to prevent multiple updates (which would be slow).

Dashed lines may also be redefined by the Dashed Lines dialog which you can choose from the Misc menu.

The dashed line patterns are saved as part of the experiment. When a new experiment is opened, the preferred dash patterns are restored.

Some programs and printer drivers do not properly render dashed lines with many “dash,skip” pairs.

Examples

```
Make test; Display test
SetDashPattern 17, {20,3,15,8}           // sets last dashed line pattern
ModifyGraph lstyle(test)=17              // apply pattern to trace
```

See Also

PauseUpdate and **ResumeUpdate** operations, and **Dashed Lines** on page III-394.

SetDataFolder

SetDataFolder *dataFolderSpec*

The SetDataFolder operation sets the current data folder to the specified data folder.

Parameters

dataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Examples

```
SetDataFolder foo                      // Sets CDF to foo in the current data folder.
SetDataFolder :bar:foo                 // Sets CDF to foo in bar current data folder.
SetDataFolder root:foo                 // Sets CDF to foo in the root data folder.
String savedDF= GetDataFolder(1)       // Remember CDF in a string.
NewDataFolder/O/S root:myFolder        // Set CDF to a new data folder.
```

SetDimLabel

```
Variable/G newVariable=1          // Do work in the new data folder.  
SetDataFolder savedDF           // Restore CDF from the string value.
```

See Also

Chapter II-8, **Data Folders**.

SetDimLabel

SetDimLabel *dimNumber*, *dimIndex*, *label*, *wavelist*

The SetDimLabel operation sets the dimension label or dimension element label to the specified label.

Parameters

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it sets the label for the entire dimension. For *dimIndex* ≥ 0 , it sets the dimension label for that element of the dimension.

label is a name (e.g., time), not a string (e.g., "time").

See Also

The **GetDimLabel** function. **Dimension Labels** on page II-93 and **Example: Wave Assignment and Indexing Using Labels** on page II-85 for further usage details and examples.

SetDrawEnv

SetDrawEnv [/W=*winName*] *keyword* [=value][, *keyword* [=value]]...

The SetDrawEnv operation sets properties of the drawing environment.

If one or more draw objects are selected in the top window then the SetDrawEnv command will apply only to those objects.

If no objects are selected *and* if the keyword *save* is *not* used *then* the command applies only to the next object drawn.

If no objects are selected *and* if the keyword “*save*” is used *then* the command sets the environment for all following objects.

Each draw layer has its own draw environment settings.

Parameters

SetDrawEnv can accept multiple *keyword=value* parameters on one line.

In the following descriptions, (*r*, *g*, *b*) specifies a color. *r*, *g*, and *b* are each a number from 0 to 65535. (0, 0, 0) specifies black. (65535, 65535, 65535) specifies white.

Also note that the abs and rel values for the coordinate keywords “xcoord” and “ycoord” are the literal characters “abs” and “rel”; they are not substitute names for numbers, names, or strings.

arrow= <i>arr</i>	Specifies the arrow head position on lines. <i>arr</i> =0: No arrowhead (default) <i>arr</i> =1: Arrowhead at end. <i>arr</i> =2: Arrowhead at start. <i>arr</i> =3: Arrowhead at start and end.
arrowfat= <i>afat</i>	Sets ratio of arrowhead width to length (default is 0.5).
arrowlen= <i>alen</i>	Sets length of arrowhead in points (default is 10).
arrowSharp= <i>s</i>	Specifies the continuously variable barb sharpness between -1.0 and 1. 0. <i>s</i> =1: No barb; lines only. <i>s</i> =0: Blunt (default). <i>s</i> =-1: Diamond.
arrowframe= <i>f</i>	Specifies the stroke outline thickness of the arrow in points (default is <i>f</i> =0 for solid fill).
astyle= <i>s</i>	Specifies which side of the line has barbs relative to a right-facing arrow. <i>s</i> =0: None. <i>s</i> =1: Top.

	<i>s</i> =2: Bottom.
	<i>s</i> =3: Both (default).
<i>dash=dsh</i>	<i>dsh</i> is a dash pattern number between 0 and 17 (see SetDashPattern for patterns). 0 (solid line) is the default.
<i>fillbgc</i> =(<i>r</i> , <i>g</i> , <i>b</i>)	Specifies fill background color. Default is the window's background color.
<i>fillfgc</i> =(<i>r</i> , <i>g</i> , <i>b</i>)	Specifies fill foreground color. The default is white.
<i>fillpat</i> = <i>fpatt</i>	Specifies fill pattern density.
	<i>fpatt</i> =-1: Erase to background color.
	<i>fpatt</i> =0: No fill.
	<i>fpatt</i> =1: 100% (solid pattern, default).
	<i>fpatt</i> =2: 75% gray.
	<i>fpatt</i> =3: 50% gray.
	<i>fpatt</i> =4: 25% gray.
<i>fname</i> ="fontName"	Sets font name, default is the default font or the graph font.
<i>fsize</i> = <i>size</i>	Sets text size, default is 12 points.
<i>fstyle</i> = <i>style</i>	Sets text style (same as for the TextBox operation), default is plain.
<i>gedit</i> = <i>flag</i>	Supplies optional edit flag for a group of objects. Use with <i>gstart</i> .
	<i>flag</i> =0: Select entire group, moveable (default).
	<i>flag</i> =1: Individual components editable as if not grouped. Allows objects to be grouped by name but still be editable
<i>gname</i> = <i>name</i>	Supplies optional <i>name</i> for an object group. Use with <i>gstart</i> .
<i>gstart</i>	Marks the start of a group of objects.
<i>gstop</i>	Marks the end of a group of objects.
<i>linebgc</i> =(<i>r</i> , <i>g</i> , <i>b</i>)	Sets the line background color. Default is window's background color.
<i>linefgc</i> =(<i>r</i> , <i>g</i> , <i>b</i>)	Sets the line foreground color, default is black.
<i>linepat</i> = <i>patt</i>	Specifies the line pattern/density.
	<i>patt</i> =1: 100% (solid pattern, default).
	<i>patt</i> =2: 75% gray.
	<i>patt</i> =3: 50% gray.
	<i>patt</i> =4: 25% gray.
<i>linethick</i> = <i>thick</i>	<i>thick</i> is a line thickness ≥ 0 , default is 1 point.
<i>origin</i> = <i>x0,d0</i>	Moves coordinate system origin to <i>x0,d0</i> . Unlike <i>translate</i> , <i>rotate</i> , and <i>scale</i> , this survives a change in coordinate system and is most useful that way. See Coordinate Transformation .
<i>pop</i>	Pops a draw environment from the stack. Pops should always match pushes.
<i>push</i>	Pushes the current draw environment onto a stack (limited to 10).
<i>rotate</i> = <i>deg</i>	Rotates coordinate system by <i>deg</i> degrees. Does not work with text and pictures. Only makes sense if X and Y coordinate systems are the same. See Coordinate Transformation .
<i>rounding</i> = <i>rnd</i>	Radius for rounded rectangles in points, default is 10.
<i>rsabout</i>	Redefines coordinate system rotation or scaling to occur at the translation point instead of the current origin. To use, combine <i>rotate</i> or <i>scale</i> with <i>translate</i> and <i>rsabout</i> parameters.
<i>save</i>	Stores the current drawing environment as the default environment.
<i>scale</i> = <i>sx,sy</i>	Scales coordinate system by <i>sx</i> and <i>sy</i> . Affects only coordinates — not line thickness or arrow head sizes. See Coordinate Transformation .
<i>textrgb</i> =(<i>r</i> , <i>g</i> , <i>b</i>)	Sets text color, default is black.
<i>textrot</i> = <i>rot</i>	Text rotation in degrees.
	Supported values are 0, 90, 180, 270, and -90.
	0 is normal (default) horizontal left-to-right text,

	90 is vertical bottom-to-top text, etc.
textxjust= <i>xj</i>	Sets horizontal text alignment. <i>xj</i> =0: Left aligned text (default). <i>xj</i> =1: Center aligned text. <i>xj</i> =2: Right aligned text.
textyjust= <i>yj</i>	Sets vertical text alignment. <i>yj</i> =0: Bottom aligned text (default). <i>yj</i> =1: Middle aligned text. <i>yj</i> =2: Top aligned text.
translate= <i>dx,dy</i>	Shifts coordinate system by <i>dx</i> and <i>dy</i> . Units are in the current coordinate system. See Coordinate Transformation .
xcoord=abs	X coordinates are absolute window coordinates (default for all windows <i>except graphs</i> where the default is xcoord=prel). The unit of measurement is pixels if the window is a panel, otherwise they are points. The left edge of the window (or of the printable area in a layout) is at x=0.
xcoord=rel	X coordinates are relative window coordinates. x=0 is at the left edge of the window; x=1 is at the right edge.
xcoord=prel	X coordinates are relative plot rectangle coordinates (graphs only). x=0 is at the left edge of the rectangle; y=1 is at the right edge of the rectangle. This coordinate system ideal for objects that should maintain their size and location relative to the axes, and <i>is the default for graphs</i> .
xcoord=axisName	X coordinates are in terms of the named axis (graphs only).
ycoord=abs	Y coordinates are absolute window coordinates (default for all windows <i>except graphs</i> where the default is ycoord=prel). The unit of measurement is pixels if the window is a panel, otherwise they are points. The top edge of the window (or the of the printable area in a layout) is at y=0.
ycoord=rel	Y coordinates are relative window coordinates. y=0 is at the top edge of the window; y=1 is at the bottom edge.
ycoord=prel	Y coordinates are relative plot rectangle coordinates (graphs only). y=0 is at the top edge of the rectangle; y=1 is at the bottom edge of the rectangle. This coordinate system ideal for objects that should maintain their size and location relative to the axes, and <i>is the default for graphs</i> .
ycoord=axisName	Y coordinates are in terms of the named axis (graphs only).

Flags

/W= <i>winName</i>	Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
--------------------	---

Coordinate Transformation

The execution order for the translate, rotate, scale, and origin parameters is important. Translation followed by rotation is different than rotation followed by translation. When using multiple keywords in one SetDrawEnv operation, the order in which they are applied is origin, translate, rotate followed by scale regardless of the command order (with the exception of the rsabout parameter). Before using origin with the save keyword, you should use push to save the current draw environment and then use pop after drawing objects using the new origin.

Examples

Following is a simple example of arrow markers:

```
NewPanel
SetDrawEnv arrow= 1,arrowlen= 30,save
SetDrawEnv arrowsharp= 0.3
DrawLine 61,67,177,31
SetDrawEnv arrowsharp= 1
DrawLine 65,95,181,59
SetDrawEnv astyle= 1
```

```
DrawLine 69,123,185,87
SetDrawEnv arrowframe= 1
DrawLine 73,151,189,115
```

You can position objects in one coordinate system and then draw them in another with the `origin` keyword. In the following coordinate transformation example, we position arrows in axis units but size them in absolute units.

```
Make/O jack=sin(x/8)
Display jack
SetDrawEnv xcoord=bottom,ycoord=left,save
SetDrawEnv push
SetDrawEnv origin=50,0
SetDrawEnv xcoord=abs,ycoord=abs,arrow=1,arrowlen=20,arrowsharp=0.2,save
DrawLine 0,0,50,0 // arrow 50 points long pointing to the right
DrawLine 0,0,0,50 // arrow 50 points long pointing down
// now let's move over, rotate a bit and draw the same arrows:
SetDrawEnv translate=100,0
SetDrawEnv rotate=30,save
DrawLine 0,0,50,0
DrawLine 0,0,0,50
SetDrawEnv pop
```

Now try zooming in on the graph. You will see that the first pair of arrows always starts at 50 on the bottom axis and 0 on the left axis whereas the second pair is 100 points to the right of the first.

See Also

Chapter III-3, **Drawing**, and the **TextBox** operation.

SetDrawLayer

SetDrawLayer [/K/W=*winName*] *layerName*

The **SetDrawLayer** operation makes all future drawing operations use the named layer.

Parameters

Valid *layerNames* for graphs:

ProgBack	UserBack	ProgAxesUserAxes
ProgFront	UserFront	

Valid *layerNames* for panels and page layouts:

ProgBack	UserBack	ProgFrontUserFront
----------	----------	--------------------

Flags

/K	Kills (erases) the given layer.
/W= <i>winName</i>	Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
	When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

There are really only two layers for Panels but **ProgFront** is allowable as an alias for **ProgBack**. Likewise **UserFront** is an alias for **UserBack**.

The back-to-front order of the layers is shown by the Environment pop-up menu if you hold down Option (Macintosh) or Alt (Windows). This is the Environment pop-up menu for graphs:

See Also

Layers on page III-76.

SetFileFolderInfo

SetFileFolderInfo [*flags*] [*fileOrFolderNameStr*]

The SetFileFolderInfo operation changes the properties of a file or folder.

Parameters

fileOrFolderNameStr specifies the file or folder to be changed.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-382 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file or folder from *fileOrFolderNameStr* and */P=pathName*, it displays a dialog allowing you to specify the file to be deleted. Use */D* to select a folder in this event, otherwise Igor prompts you for a file.

Flags

At least one of the seven following flags is required, or nothing is actually accomplished:

- | | |
|--------------------|---|
| <i>/CDAT=cdate</i> | Specifies the number of seconds since midnight January 1, 1904 when the file or folder was first created. |
| <i>/INV[=inv]</i> | Sets the visibility of a file.
<i>inv</i> =0: File is visible.
<i>inv</i> =1: Default; file is invisible (Macintosh) or Hidden (Windows). |
| <i>/MDAT=mDate</i> | Specifies the number of seconds since midnight January 1, 1904 when the file or folder was modified most recently. |
| <i>/RO[=ro]</i> | Sets the read/write state of a file or folder.
<i>ro</i> =0: File or folder is writable.
<i>ro</i> =1: File or folder is locked (default).
On Windows, set <i>ro</i> to any nonzero value to make it read-only. To set the read-only property manually, right-click the file and choose "Properties", then select or deselect the "read-only" checkbox.
On Macintosh, <i>ro</i> is a bitmap of two settings:
Bit 0: Unlocked.
Bit 1: "Locked" with the Finder. Only files can be locked this way.
You set this kind of locking with the Finder's Get Info window by selecting the "Locked" checkbox.
Bit 2: "File Locked" as with ResEdit. You can't set this kind of locking with the Finder, but applications can. See SetFileFolderInfo.
Bit 3: Both kinds of locking are set.
See Setting Bit Parameters on page IV-11 for details about bit settings. |

If *fileOrFolderNameStr* refers to a file (not a folder), SetFileFolderInfo updates the file properties to reflect values given with the following keywords:

- | | |
|-------------------------|--|
| <i>/CRE8=creatorStr</i> | Sets the four-character creator code string, such as 'IGR0' (Igor Pro creator code).
Ignored on Windows, where files have no "creator code"; instead file extensions are "registered" or "owned" by one, and only one, application. You cannot change that ownership from Igor Pro. |
| <i>/FTYP=fTypeStr</i> | Sets the four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment).
Ignored on Windows. Use MoveFile to change the file extension. |
| <i>/STA[=st]</i> | Specifies whether the file is a stationery file or not.
<i>st</i> =1: Stationery file (default).
<i>st</i> =0: Normal file.
Ignored on Windows. Use MoveFile to change the file extension. |

Optional Flags

/D	Uses the Select Folder dialog rather than Open File dialog when <i>pathName</i> and <i>fileOrFolderNameStr</i> do not specify an existing file or folder.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/R[= <i>r</i>]	<p>Recursively applies change(s) to all files or folders in the folder specified by /P=<i>pathName</i> or <i>fileOrFolderNameStr</i>, and the folder itself:</p> <p><i>r</i>=0: No recursion. Same as no /R.</p> <p><i>r</i>=1: Recursively apply changes to files.</p> <p><i>r</i>=2: Recursively apply changes to folders, including the folder specified by <i>pathName</i> or <i>fileOrFolderNameStr</i>.</p> <p><i>r</i>=3: Recursively apply changes to both files and folders (default).</p> <p>/R requires /D and a folder specification.</p>
/Z	Prevents procedure execution from aborting if SetFileFolderInfo tries to set information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

Variables

SetFileFolderInfo returns information about the file or folder in the following variables:

V_flag	0: File or folder was found.
	-1: User cancelled the Open File dialog.
	>0: An error occurred, such as the specified file or folder does not exist.
S_path	File system path of the selected file or folder.

Examples

Change the file creator code; no complaint if it doesn't exist:

```
SetFileFolderInfo/Z /CRE8="CWIE", "Macintosh HD:folder:afile.txt"
```

Set the file modification date:

```
Variable mDate= Date2Secs(2000,12,25) + hrs*3600+mins*60+secs
SetFileFolderInfo/P=myPath/MDAT=(mDate), "afile.txt"
```

Remove read-only property from a folder and everything within it:

```
SetFileFolderInfo/P=myPath/D/R/RO=0
```

See Also

The **GetFileFolderInfo**, **ImageFileInfo**, **MoveFile**, and **FStatus** operations. The **IndexedFile**, **date2secs**, and **ParseFilePath** functions.

SetFormula

SetFormula *waveName*, *expressionStr*

SetFormula *variableName*, *expressionStr*

The SetFormula operation binds the named wave, numeric or string variable to the expression or, if the expression is "", unbinds it from any previous expression. In user functions, SetFormula must be used to create dependencies.

Parameters

expressionStr is a string containing a numeric or string expression, depending on the type of the bound object.

Pass "" (empty string) for *expressionStr* to clear any previous dependency expression associated with the wave or variable.

Details

The dependent object (the wave or variable) will depend on the objects referenced in the string expression. The expression will be reevaluated any time an object referred to in the expression is modified.

Besides being set from a string expression this differs from just typing:

```
name := expression
```

in that syntax errors in *expressionStr* are not reported and are not fatal. You end up with a dependency assignment that is marked as needing to be recompiled. The recompilation will be attempted every time an object is created or when the procedure window is recompiled.

SetIgorHook

Use the Object Status dialog in the Misc menu to check up on dependent objects.

Examples

This command makes the variable `v_sally` dependent on the user-defined function `anotherFunction`, waves `wave_fred` and `wave_sue`, and the system variable `K2`:

```
SetFormula v_sally, "anotherFunction(wave_fred[1]) + wave_sue[0] + K2"
```

This is equivalent to:

```
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
```

except that no error will be generated for the `SetFormula` if, for instance, `wave_fred` does not exist.

A string variable dependency can be created by a command such as:

```
SetFormula myStringVar, "note(wave_joe)"
```

observe that *expressionStr* is a string *containing* a string expression, and that:

```
SetFormula myStringVar, note(wave_joe)
```

is not the same thing. In this case the note of `wave_joe` would contain the expression that `myStringVar` would depend on! Also, `wave_joe` would have to exist for Igor to understand the statement.

See Also

Chapter IV-9, **Dependencies**, and the **GetFormula** function.

SetIgorHook

SetIgorHook [/K/L] [*hookType* = [*procName*]]

The `SetIgorHook` operation calls a user-defined “hook” function during certain events, such as file-opening, cursor-moving, menu selection, Igor startup, or Igor quitting. (The term “hook” is used as in the phrase “to hook into”, meaning to intercept or to attach.)

More than one user-defined function can be called for each event. This avoids the main problem associated with fixed-name functions (see **User-Defined Hook Functions** on page IV-197): multiple procedure files that each define the same nonstatic fixed-name functions (such as **IgorBeforeQuitHook**) causing compilation errors.

Flags

- /K Removes *procName* from the list of functions called for the *hookType* events.
If *procName* is not specified all *hookType* functions are removed.
If *hookType* is not specified all functions are removed for all *hookType* events, returning Igor to the pre-`SetIgorHook` state.
- /L Executes *procName* last. Without /L, a newly added hook function runs before previously registered hook functions.
A function that has been previously registered with `SetIgorHook` can be moved from being called first to being called last by calling `SetIgorHook` again with /L.
To move a function from being called last to being called first requires removing the hook function with /K and then calling `SetIgorHook` without /L.

Parameters

hookType Specifies one of the fixed-name hook function names:

AfterFileOpenHook
AfterWindowCreatedHook
BeforeExperimentSaveHook
BeforeFileOpenHook
IgorBeforeNewHook
IgorBeforeQuitHook
IgorMenuHook
IgorQuitHook
IgorStartOrNewHook

See the note below about these *hookType* names.

hookType is required except with /K.

procName Names the user-defined hook function that is called for the *hookType* event.

Details

The syntax of the user-defined function *procName* varies depending on the *hookType* it is registered for.

For example, a function registered for the AfterFileOpenHook type must have the same syntax as the shown for the **AfterFileOpenHook** on page IV-198.

The *procName* function is called *after* any window-specific hook for these *hookTypes*, and the *procName* function is called *before* any other hook functions previously registered by calling SetIgorHook *unless the /L flag is given*, in which case it still runs after window-specific hook functions, but also *after* all other previously registered hook functions.

The *procName* function should return nonzero to prevent later functions from being called (1 is typical). Returning 0 allows successive functions to be called.

After all the SetIgorHook functions registered for *hookType* have run (and all have returned 0), any static fixed-name hook functions are called and then the (only) fixed-name user-defined hook function, if any, is called. As an example, when a menu event occurs, Igor handles the event by calling the top window's hook function, any SetIgorHook-registered hook functions, and then all of the fixed-named IgorMenuHook functions (first any static IgorMenuHook functions, and then the one-and-only nonstatic **IgorMenuHook** function):

SetWindow event (called first)	SetIgorHook <i>hookType</i> (called second)	User-defined Hook Function(s) (called last)
enableMenu	IgorMenuHook	IgorMenuHook
menu	IgorMenuHook	IgorMenuHook

Note: Although you can technically use one of the fixed-name functions, as described in **User-Defined Hook Functions** on page IV-197, for *procName*, the result would be that the function will be called twice: once as a registered named hook function and once as the fixed-named hook function. That is, don't use SetIgorHook this way:

```
SetIgorHook AfterFileOpenHook=AfterFileOpenHook           // NO NO
```

SetIgorHook does not work at Igor start or new experiment time, so instead of SetIgorHook IgorStartOrNewHook, use the global **IgorStartOrNewHook** function (see page IV-206).

Variables

SetIgorHook returns information in the following variables:

S_info Semicolon-separated list of all current hook names associated with *hookType*, listed in the order in which they are called.

Examples

This hook function invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for a graph, preventing the usual Copy.

```
SetIgorHook IgorMenuHook=CopyIsExportHook
```

```
Function CopyIsExportHook(isSelection,menuName,itemName,itemNo,win,wType)
  Variable isSelection
  String menuName,itemName
  Variable itemNo
  String win
  Variable wType
  Variable handledIt= 0
  if( isSelection && wType==1 )    // menu was selected, window is graph
    if( CmpStr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0 )
      DoIgorMenu "Edit", "Export Graphics"    // dialog instead
      handledIt= 1    // don't call other IgorMenuHook functions.
    endif
  endif
  return handledIt
End
```

To unregister CopyIsExportHook as a hook procedure:

```
SetIgorHook/K IgorMenuHook=CopyIsExportHook    // unregister CopyIsExportHook
```

To discover which functions are associated with a *hookType*, use a command such as:

SetIgorMenuMode

```
SetIgorHook IgorMenuHook    // inquire about names registered for IgorMenuHook
Print S_info                // list of functions
```

To remove (or “unregister”) named hooks:

```
SetIgorHook/K              // removes all hook functions for all hookTypes
SetIgorHook/K IgorMenuHook // removes all IgorMenuHook functions
SetIgorHook/K IgorMenuHook=CopyIsExportHook // removes only this hook function
```

See Also

The **SetWindow** operation and **User-Defined Hook Functions** on page IV-197.

SetIgorMenuMode

SetIgorMenuMode *MenuNameStr*, *MenuItemStr*, *Action*

The SetIgorMenuMode operation allows an Igor programmer to disable or enable Igor’s built-in menus and menu items. This is useful for building applications that will be used by end-users who shouldn’t have access to all Igor’s extensive and confusing functionality.

Parameters

<i>MenuNameStr</i>	The name of an Igor menu, like “File”, “Graph”, or “Load Waves”.
<i>MenuItemStr</i>	The text of an Igor menu item, like “Copy” (in the Edit menu) or “New Graph” (in the Windows menu).
<i>Action</i>	One of DisableItem, EnableItem, DisableAllItems, or EnableAllItems. DisableItem and EnableItem disable or enable just the single item named by <i>MenuNameStr</i> and <i>MenuItemStr</i> . If <i>MenuItemStr</i> is “”, then the menu itself is disabled. DisableAllItems and EnableAllItems disable and enable all the items in the menu named by <i>MenuNameStr</i> .

Details

All menu names and menu item text are in English. This ensures that code developed for a localized version of Igor will run on all versions. Note that no trailing “...” is used in *MenuItemStr*.

The SetIgorMenuModeProc.ipf procedure file includes procedures and commands that disable or enable every menu and item possible. It is in your Igor Pro folder, in WaveMetrics Procedures:Utilities:. It is not intended to be used as-is. You should make a copy and edit the copy to include just the parts you need.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use “Save Window”, “Save Window As”, “Save Window Copy”, “Adopt Window” and “Revert Window” instead of “Save Notebook” or “Save Procedure”, etc. Use “Page Setup” instead of “Page Setup For All Graphs”, etc. Use “Print” instead of “Print Graph”, etc.

See Also

The **DoIgorMenu** operation.

SetIgorOption

SetIgorOption [*mainKeyword*,] *keyword*= *value*

SetIgorOption [*mainKeyword*,] *keyword*= ?

The SetIgorOption operation makes unusual and temporary changes to Igor Pro’s behavior. This operation is not compilable and you will need to use the **Execute** operation to use it in a user function. The details of the syntax depend on the application and are documented where the alternate behaviors are described. In most cases the current value of a setting can be read using the *keyword*=? syntax. Simple numeric options are stored in V_flag and color options are stored in V_Red, V_Green, and V_Blue. The settings last for the life of the Igor session.

See Also

Syntax Coloring on page III-339 for some usage examples; **Macintosh and LAPACK Library** on page III-140; **Limitations of Independent Modules** on page IV-41; **Conditional Compilation** on page IV-68; **Pre-Carbon Page Setup Records** on page III-381. **MarkPerfTestTime** operation.

SetMarquee

SetMarquee [/W=*winName*] *left, top, right, bottom*

The SetMarquee operation creates a marquee on the target graph or layout window or the specified window or subwindow. The *left, top, right, bottom* coordinates are the same as those returned by the GetMarquee operation (screen units measured in points).

The optional axis modes supported by GetMarquee are not supported by SetMarquee.

Flags

/W=*winName* Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

The **GetMarquee** operation.

SetProcessSleep

SetProcessSleep *sleepTicks*

The SetProcessSleep operation determines how much time Igor will give to background tasks or other Macintosh applications executing in the background. This operation does nothing on Windows.

Parameters

sleepTicks is the amount of time given to background tasks in sixtieths of a second. *sleepTicks* values between 0 and 60 are valid.

Details

Igor starts up with *sleepTicks* = 1. Use 0 to give Igor maximum time, use a larger number to give other applications more time.

Background tasks are used mainly by data acquisition programs.

See Also

Background Task on page IV-211 and the **SetBackground** operation.

SetRandomSeed

SetRandomSeed *seed*

The SetRandomSeed operation seeds the random number generator used for the **ennoise** and **gnoise** functions. Use SetRandomSeed if you need “random” numbers that are reproducible. If you don’t use SetRandomSeed, the random number generator is initialized using the system clock when Igor starts. This almost guarantees that you will never get the same sequence twice unless you use SetRandomSeed.

Parameters

seed should be a number from 0 to 1. For any given *seed*, **ennoise** or **gnoise** generates a particular sequence of pseudorandom numbers. Calling SetRandomSeed with a *seed* of your choice restarts and repeats the sequence.

See Also

The **ennoise** and **gnoise** functions.

SetScale

SetScale [/I/P] *dim, num1, num2* [, *unitsStr*] ,*waveName* [, *waveName*]...

SetScale *d, num1, num2* [, *unitsStr*] , *waveName* [, *waveName*]...

The SetScale operation sets the dimension scaling or the data full scale for the named waves.

Parameters

The first parameter *dim* must be one of the following:

Character	Signifies
d	Data full scale.
t	Scaling of the chunks dimension (t scaling).

Character	Signifies
x	Scaling of the rows dimension (x scaling).
y	Scaling of the columns dimension (y scaling).
z	Scaling of the layers dimension (z scaling).

If setting the scaling of any dimension (*x*, *y*, *z*, or *t*), *num1* is the starting index value — the scaled index for the first point in the dimension. The meaning of *num2* changes depending on the /I and /P flags. If you use /P, then *num2* is the delta value — the difference in the scaled index from one point to the next. If you use /I, *num2* is the “ending value” — the index value for the last element in the dimension. If you use neither flag, *num2* is the “right value” — the index value that the element *after the last element in the dimension* would have.

These three methods are just three different ways to specify the two scaling values, the starting value and the delta value, that are stored for each dimension of each wave.

If setting the data full scale (*d*), then *num1* is the nominal minimum and *num2* is the nominal maximum data value for the waves. The data full scale values are not used. They serve only to document the minimum and maximum values the waves are expected to attain. No flags are used when setting the data full scale.

The *unitsStr* parameter is a string that identifies the natural units for the *x*, *y*, *z*, *t*, or data values of the named waves. Igor will use this to automatically label graph axes. This string must be one to 49 characters such as “m” for meters, “g” for grams or “s” for seconds. If the waves have no natural units you can pass “” for this parameter.

Flags

At most one flag is allowed, and then only if dimension scaling (not data full scale) is being set:

/I	Inclusive scaling. <i>num2</i> is the ending index — the index value for the very last element in the dimension.
/P	Per-point scaling. <i>num2</i> is the delta index value — the difference in scaled index value from one element to the next.

Details

SetScale will not allow the delta scaling value to be zero. If you execute a SetScale command with a delta value of zero, it will set the delta value to 1.0.

If you do not use the /P flag, SetScale converts *num1* and *num2* into a starting index value and a delta index value. If you call SetScale on a dimension with fewer than two elements, it does this conversion as if the dimension had two elements.

Prior to Igor Pro 3.0, Igor supported only 1D waves. “SetScale x” was used to set the scaling for the rows dimensions and “SetScale y” was used to set the data full scale. With the addition of multidimensional waves, “SetScale y” is now used to set the scaling of the columns dimension and “SetScale d” is used to set the data full scale. For backward compatibility, “SetScale y” on a 1D wave sets the data full scale.

When setting the dimension scaling of a numeric wave, you can omit the *unitsStr* parameter. Igor will set the wave’s scaling but not change its units. However, when setting the dimension scaling of a text wave, you must supply a *unitsStr* parameter (use “” if the wave has no units). If you don’t, Igor will think that the text wave is the start of a string expression and will attempt to treat it as the *unitsStr*.

Note: Prior to Igor Pro 3.0, SetScale with no wave names would set the default characteristics for waves made subsequently with the Make command. In Igor Pro 2.0, this behavior was considered obsolete and the manual warned that it was not recommended. As of Igor Pro 3.0 SetScale will still set the default x scaling, but will beep and put up a warning dialog. In future versions, SetScale without a wave name will not work. At present, you cannot set the default y, z, or t scaling with SetScale.

See Also

The **Make** command. For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-70.

SetVariable

SetVariable [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The SetVariable operation creates or modifies a SetVariable control in the target window.

A SetVariable control sets the value of a global numeric or string variable when you type or click in the control. As of Igor Pro version 4.04, a SetVariable can also be attached to a specific point in a wave.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the SetVariable control to be created or changed.

key is one of the following parameters:

activate	Activates the control and selects the text that sets the value. Use ControlUpdate to deactivate the control and deselect the text.
appearance={ <i>kind</i> [, <i>platform</i>]}	Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings. <i>kind</i> can be one of <code>default</code> , <code>native</code> , or <code>os9</code> . <i>platform</i> can be one of <code>Mac</code> , <code>Win</code> , or <code>All</code> . See Button and DefaultGuiControls for more appearance details.
bodyWidth= <i>width</i>	Specifies an explicit size for the body (nontitle) portion of a SetVariable control. By default (<code>bodyWidth=0</code>), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size or text of the title changes, then the body portion may grow or shrink. If you supply a <code>bodyWidth>0</code> , then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
disable= <i>d</i>	Sets user editability of the control. <i>d=0</i> : Normal. <i>d=1</i> : Hide. <i>d=2</i> : No user input.
font=" <i>fontName</i> "	Sets the font used to display the value of the variable, e.g., <code>font="Helvetica"</code> .
format= <i>formatStr</i>	Sets the numeric format of the displayed value, e.g., <code>format="%g"</code> . Not used with string variables. Never use leading text or the "%W" formats, because Igor reads the value back without interpreting the units. For a description of <i>formatStr</i> , see the printf operation.
frame= <i>f</i>	<i>f=0</i> : Value unframed. <i>f=1</i> : Value framed (default).
fsiz= <i>s</i>	Sets the size of the type used to display the variable's value.
fstyle= <i>fs</i>	<i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>). See Setting Bit Parameters on page IV-11 for details about bit settings.
help={ <i>helpStr</i> }	Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.
labelBack=(<i>r,g,b</i>) or 0	Specifies the background fill color for labels. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. The default is 0, which uses the window's background color.
limits={ <i>low,high,inc</i> }	Sets the limits of the allowable values (<i>low</i> and <i>high</i>) for the variable. <i>inc</i> sets the amount by which the variable is incremented if you click the control's up/down arrows. This applies to numeric variables, not to string variables. If <i>inc</i> is zero then the up/down arrows will not be drawn.
live= <i>l</i>	<i>l=0</i> : Update only after variable changes (default).

	<i>l</i> = 1: Update as variable changes.
<i>noedit=val</i>	<i>noedit</i> =1 prevents the user from clicking (or tabbing into) a SetVariable control to directly edit its value. This is useful when you want to make a string read-only or when you want to restrict a numeric setting to those available only via the control's up or down arrow buttons. <i>noedit</i> =0 reactivates user editing.
<i>noproc</i>	No procedure is to execute when the control's value is changed.
<i>pos={left,top}</i>	Sets position of control in pixels.
<i>proc=procName</i>	Sets the procedure to execute when the control's value is changed.
<i>rename=newName</i>	Gives control a new name.
<i>size={width,height}</i>	Sets width of control in pixels. <i>height</i> is ignored.
<i>title=titleStr</i>	Sets title of control to the specified string expression. The title is displayed to the left of the control. If <i>titleStr</i> is empty (" "), the name of the controlled variable is displayed as the title. Use <i>title=" "</i> (put a space within the quotation marks) to create a "blank" title.
<i>userdata(UDName)=UDStr</i>	Sets the unnamed user data to <i>UDStr</i> . Use the optional (<i>UDName</i>) to specify a named user data to create.
<i>userdata(UDName)+=UDStr</i>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional (<i>UDName</i>) to append to the named <i>UDStr</i> .
<i>value=varName</i>	Sets the numeric or string variable or wave to be controlled. If wave, the point is specified using standard bracket notation with either a numeric point number or a row label, for example: <i>value=awave[4]</i> or <i>value=awave[%aLabel]</i> . You may also use a matrix wave and specify a column index in addition to the row index.
<i>win=winName</i>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The procedure, which may be a function *or* a macro, has the format:

```
Function procName(ctrlName,varNum,varStr,varName) : SetVariableControl
    String ctrlName
    Variable varNum      // value of variable as number
    String varStr        // value of variable as string
    String varName       // name of variable
    ...
End
```

The ": SetVariableControl" puts the procedure in the Procedure pop-up menu in the SetVariable Control dialog.

The action procedure for a SetVariable control can also use a predefined structure **WMSetVariableAction** as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a SetVariable control, otherwise it will use the old-style method.

A SetVariable action procedure using a structure has the format:

```
Function newActionProcName(SV_Struct)
    STRUCT WMSetVariableAction &SV_Struct
    ...
End
```

For a SetVariable control, the `WMSetVariableAction` structure has members as described in the following table:

WMSetVariableAction Structure Members

Member	Description										
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.										
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.										
<code>STRUCT Rect winRect</code>	Local coordinates of host window.										
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.										
<code>STRUCT Point mouseLoc</code>	Mouse location.										
<code>Int32 eventCode</code>	Event that executed the procedure.										
<table> <tr> <th>eventCode</th><th>Event</th></tr> <tr> <td>-1</td><td>Control being killed</td></tr> <tr> <td>1</td><td>Mouse up</td></tr> <tr> <td>2</td><td>Enter key</td></tr> <tr> <td>3</td><td>Live update</td></tr> </table>		eventCode	Event	-1	Control being killed	1	Mouse up	2	Enter key	3	Live update
eventCode	Event										
-1	Control being killed										
1	Mouse up										
2	Enter key										
3	Live update										
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of <code>MODIFIERS: flags</code> for SetWindow under Unnamed Hooks on page V-505.										
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.										
<code>Int32 isStr</code>	TRUE for a string variable.										
<code>double dval</code>	Numeric value of variable.										
<code>char sval[MAXCMDLEN]</code>	Value of variable as a string.										
<code>char vName[MAX_OBJ_NAME+2+MAX_OBJ_NAME+4+1]</code>	Name of variable or wave. Dimension labels can be used for waves.										
<code>WAVE svWave</code>	Valid if using wave.										
<code>Int32 rowIndex</code>	Row index for a wave, unless <code>rowLabel</code> is not null.										
<code>char rowLabel[MAX_OBJ_NAME+1]</code>	Wave row label.										
<code>Int32 colIndex</code>	Column index for a wave, unless <code>colLabel</code> is not null.										
<code>char colLabel[MAX_OBJ_NAME+1]</code>	Wave column label.										

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

Examples

Executing the commands:

```
Variable/G globalVar=99
SetVariable setvar0 size={120,20}
SetVariable setvar0 font="Helvetica", value=globalVar
```

creates this SetVariable control:

globalVar 

See Also

The **printf** operation for an explanation of *formatStr*, and **Set Variable** on page III-348.

SetVariableControl

The **ControlInfo** operation for information about the control. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

SetVariableControl

SetVariableControl

SetVariableControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined SetVariable control. See **Procedure Subtypes** on page IV-149 for details.

SetWaveLock

SetWaveLock *lockVal*, *waveList*

The SetWaveLock operation locks a wave or waves and protects them from modification. Such protection is not absolute, but it should prevent most common attempts to change or kill a wave.

Parameters

lockVal can be 0, to unlock, or 1, to lock the wave(s).

waveList is a list of waves or it can be **allInCDF** to act on all waves in the current data folder.

SetWindow

SetWindow *winName* [, *keyword* = *value*]...

The SetWindow operation sets the window note and user data for the named window or subwindow. SetWindow can also set hook functions for a base window or exterior subwindow (interior subwindows not supported).

Parameters

winName can be a window or subwindow name. It can also be the keyword **kwTopWin** to specify the topmost graph, panel, layout, table, or notebook window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

hide = <i>h</i>	Hides or unhides widows or subwindows. <i>h</i> =0: Unhides a subwindow or base window <i>h</i> =1: Hides a subwindow or base window. <i>h</i> =2: Unhides without restoring minimized windows (<i>Windows</i> only). When un hiding subwindows, you should combine with needUpdate=1 if conditions require the subwindow to be redrawn since the window was hidden.
hook= <i>procName</i>	Sets the name of the function called when certain events happen. Use SetWindow hook="\$ " to specify no hook function. See Unnamed Hooks for further details.
hook(<i>hName</i>)= <i>procName</i>	Defines a named hook <i>hName</i> and sets the name of the function called when certain events happen. <i>hName</i> can be any legal name. Named hooks are called before any unnamed hooks. The <i>procName</i> hook function must use the WMWinHookStruct structure as a parameter. See Named Hooks for further details.
hookcursor= <i>number</i>	Uses the cursor specified by hookcursor in the interior of the window if hook is specified, if hookevents bit 1 is set, and if hookcursor is nonzero. Currently, there are 27 cursors.
hookevents= <i>flags</i>	Bitfield of flags to enable certain events: bit 0: Mouse button clicks. bit 1: Mouse moved events. bit 2: Cursor moved events. To set bit 0 and bit 1 (mouse clicks and mouse moved), use $2^0 + 2^1 = 1 + 2 = 3$ for <i>flags</i> . Use 7 to also enable cursor moved events. See Setting Bit Parameters on page IV-11 for details about bit settings.
needUpdate= <i>n</i>	Marks a window as needing an update (<i>n</i> =1) or takes no action (<i>n</i> =0).
note= <i>noteStr</i>	Sets the window note to <i>noteStr</i> , replacing any existing note.
note+= <i>noteStr</i>	Appends <i>noteStr</i> to current contents of the window note.

`userdata=UDStr`

`userdata(UDName)=UDStr`

Sets the window or subwindow user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

`userdata+=UDStr`

`userdata(UDName)+=UDStr`

Appends *UDStr* to the current window or subwindow user data. Use the optional (*UDName*) to append to the named user data.

Unnamed Hooks

The hook function is called when various window events take place. The reason for the hook function call is stored as an event code in the hook function's *infoStr* parameter. This is used for advanced user controls.

The hook function is not called during experiment creation or load time so as to prevent the hook function from failing because the experiment is not fully recreated.

The hook function has the following syntax:

```
Function procName(infoStr)
  String infoStr
  String event= StringByKey("EVENT",infoStr)
  ...
  return statusCode           // 0 if nothing done, else 1
End
```

infoStr is a string which will contain a semicolon separated list of *key:value* pairs:

EVENT:	<i>eventKey</i>	<i>eventKey</i> identifies the event:
	activate	Window has just been activated.
	copy	Copy menu item has been selected.
	deactivate	Window has just been deactivated.
	enablemenu	Menus are being built and enabled.
	hide	Window or subwindows about to be hidden.
	kill	Window is being killed.
	killVote	Window is about to be killed. Return 2 to prevent that, otherwise return 0 (see Notes on Events 14-17 and 2).
	menu	A built-in menu item has been selected.
	modified	A modification to the graph has been made (graphs only).
	moved	Window has just been moved.
	renamed	Window has just been renamed. The previous name is available under the OLDWINDOW key.
	resize	Window has just been resized.
	show	Window or subwindows is about to be unhidden.
	subwindowKill	One of the window's subwindows is about to be killed.

Note: The copy event introduced in Igor 4.03 has been replaced by the menu event. If the corresponding *hookevents* flag bits are set, then the following events will also be reported. If the hook function returns a nonzero value then Igor will not do its usual processing.

mousedown When the mouse button is clicked (bit 0).

mousemoved Called continuously as the mouse is moved (bit 1).

mouseup Mouse button is released (bit 0).

HCSPEC:winName Absolute path of the window or subwindow. See **Subwindow Command Concepts** on page III-92.

MODIFIERS:flags Bits set based on state of certain keys:

bit 0: Set if mouse button is down.

bit 1: Set if Shift is down.

- bit 2: Set if Option (*Macintosh*) or Alt (*Windows*) is down.
- bit 3: Set if Command (*Macintosh*) or Ctrl (*Windows*) is down.
- bit 4: Contextual menu click: right-click or Control-click (*Macintosh*), or right-click (*Windows*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

OLDWINDOW: *winName* Previous name of the window or subwindow (for renamed event). Not the old absolute path *hcSpec*, just the name. WINDOW and HCSPEC contain the new name and new *hcSpec*.

WINDOW: *winName* Name of the window.

Returning a value of 2 for the kill message will prevent Igor from killing the associated window.

The modified event (added in Igor 4.05) is issued only when a graph updates (See **DoUpdate**, **PauseUpdate**, and **ResumeUpdate**). Most changes to the graph are accompanied by the modified event, but not all: changing an annotation will not trigger the event, nor will adding, removing, or modifying a control or showing or hiding the drawing tools while using the /A flag. The modified event is not sent while a trace is being dragged or when the values of a trace's wave change (unless one the trace's axes is autoscaled). However, changing an axis range or indeed changing almost anything about axes or showing or hiding the info pane will send the modified event (only one event per graph update). When in doubt, use a print statement to determine when the event is sent.

If mouse events are reported then the following will also be present:

MOUSEX: *x pixel* X coordinate in pixels of the mouse.

MOUSEY: *y pixel* Y coordinate in pixels of the mouse.

TICKS: *time* Time event happened.

Note that a mouseup event may or may not correspond to a previous mousedown. If the user clicks in the window, drags out and releases the button then the mouseup event will be missing. If the user clicks in another window, drags into this one and then releases then a mouseup will be sent that had no previous mousedown.

In the case of mousedown or mousemoved messages, a nonzero return value will skip normal processing of the message. This is most useful with mousedown.

The **cursormoved** event not reported if Option (*Macintosh*) or Alt (*Windows*) is held down. It is also not reported unless the **hookevents** bit 2 is set.

If the **cursormoved** event is reported then the following will also be present:

CURSOR: *A - J* Name of the cursor that moved.

TNAME: *traceName* Name of the trace the cursor is attached to (invalid if **ISFREE**=1).

ISFREE: *free* 1 if the cursor is "free" (not attached to a trace), 0 if it is attached to a trace or image.

POINT: *pt* Point number of *traceName* if not a free cursor. If the cursor is attached to an image, *pt* is the row number of the image.

If a free cursor, *pt* is the fraction of the plot width, 0 being the left edge of the plot area, and 1 being the right edge.

YPOINT: *yPt* Column number if the cursor is attached to an image, NaN if attached to a trace.

If a free cursor, *yPt* is the fraction of the plot height, 0 being the top edge, and 1 being the bottom edge.

If the a menu event is reported then the following will also be present:

MENUNAME: *menuStr* Name of menu (in English) as used by **SetIgorMenuMode**.

MENUITEM: *itemStr* Text of menu item as used by **SetIgorMenuMode**.

(The **enablemenu** event does not pass **MENUNAME** or **MENUITEM**).

The **menu** and **enablemenu** messages are not sent during when drawing tools are in use in a graph or layout or when waves are being edited in a graph.

Returning a value of 0 for the **enablemenu** message is recommended, though its value is (currently) ignored.

You can use the **SetIgorMenuMode** operation to alter the enable state of Igor's built-in menus in a way you find appropriate for the window. If you do this, usually you will also handle the menu message and perform your idea of an appropriate action.

Note: Dynamic user-defined menus (see **Dynamic Menu Items** on page IV-91) are built and enabled by using string functions in the menu definitions.

Returning a value of 0 for any menu message allows Igor to perform the normal action. Returning any other value (1 is commonly used) does not perform the normal action.

See the user function description with **IgorMenuHook** on page IV-204 for details on the sequence of menu building, enabling, and handling.

Note: Returning a value of 2 for the copy menu item message is no longer handled specially by Igor Pro 5. In Igor Pro 4 it invoked the Export Graphics dialog. The second example below shows the new way of doing this.

Named Hooks

When using named window hooks, your hook function must use a predefined structure **WMWinHookStruct** as a parameter. This structure will provide your function with information about the status of various window events. See **Structures in Functions** on page IV-61.

The function prototype used with a named hook has the format:

```
Function myWindowHook(H_Struct)
    STRUCT WMWinHookStruct &H_Struct
    <code to test and process events>
    ...
    return statusCode          // 0 if nothing done, else 1
End
```

The **WMWinHookStruct** structure has members as described in the following tables:

Base WMWinHookStruct Structure Members

Member	Description
char winName[MAX_PATH_LENGTH+1]	hSpec of the affected (sub)window.
STRUCT Rect winRect	Local coordinates of the affected (sub)window.
STRUCT Point mouseLoc	Mouse location.
double ticks	Tick count when event happened.
Int32 eventCode	See see Event Code table on page V-508.
char eventName[31+1]	Name-equivalent of eventCode, see Event Code table on page V-508. Added in Igor 5.03.
Int32 eventMod	Bitfield of modifiers. See description for MODIFIERS: flags .

Members of WMWinHookStruct Structure Used with menu Code

Member	Description
char menuName[255+1]	Name of menu (in English) as used by SetIgorMenuMode .
char menuItem[255+1]	Text of the menu item as used by SetIgorMenuMode

Members of **WMWinHookStruct** Structure Used with **cursormoved** Code

Member	Description
char traceName[MAX_OBJ_NAME+1]	The name of the trace or image to which the moved cursor is attached or which supplies the X (and Y) values. Can be "" if the cursor is free.
char cursorName[2]	Cursor name A through J.
double pointNumber	Point number of the trace or the X (row) point number of the image where the cursor is attached. If the cursor is "free", pointNumber is actually the fractional relative <i>xValue</i> as used in the Cursor /F/P command.
double yPointNumber	Valid only when the cursor is attached to a two-dimensional item such as an image, contour, or waterfall plot, or when the cursor is free. If attached to an image, contour, or waterfall plot, yPointNumber is the Y (column) point number of the image where the cursor is attached. If the cursor is "free", yPointNumber is actually the fractional relative <i>yValue</i> as used in the Cursor /F/P command.
Int32 isFree	Has value of 1 if the cursor is not attached to anything, or value of 0 if it is attached to a trace, image, contour, or waterfall.

User-Modifiable Members of **WMWinHookStruct** Structure

Member	Description
Int32 doSetCursor	Set TRUE to change cursor to that specified by cursorCode.
Int32 cursorCode	Standard cursor as set by hookcursor= <i>number</i> .

Members of **WMWinHookStruct** Used with **renamed** Code

Member	Description
char oldWinName[MAX_OBJ_NAME+1]	Old name of the window or subwindow. Not the absolute path <i>hcSpec</i> , just the name.

Members of **WMWinHookStruct** Structure Used with **keyboard** Code

Member	Description
Int32 keycode	ASCII value of key struck. Function keys are not available but navigation keys are translated to specific values and will be the same on Macintosh and Windows.

When determining the state of the **eventCode** member of the **WMWinHookStruct** structure, the various **eventCode** and **eventName** values you use in your window hook function are defined as:

Event Code	eventName	Notes
0	"Activate"	
1	"Deactivate"	
2	"Kill"	
3	"Mousedown"	

Event Code	eventName	Notes
4	"Mousemoved"	
5	"Mouseup"	
6	"Resize"	
7	"Cursormoved"	See Cursors — Moving Cursor Calls Function on page IV-220.
8	"Modified"	
9	"Enablemenu"	
10	"Menu"	
11	"Keyboard"	Not sent to unnamed window hook functions.
12	"moved"	
13	"renamed"	
14	"subwindowKill"	One of the window's subwindows is about to be killed.
15	"hide"	The window or one of its subwindows is about to be hidden.
16	"show"	The window or one of its subwindows is about to be unhidden.
17	"killVote"	Window is about to be killed. Return 2 to prevent the window from being killed, otherwise return 0. Note: Don't delete data structures during this event, use killVote only to decide whether the window kill should actually happen. Delete data structures in the kill event. See Notes on Events 14-17 and 2 .

Named hooks are called for all events and ignore any hookevents settings. You should respond only to events you know about, and return a nonzero value only when you want to cut short any further event handing by any other hooks or by Igor.

The principal reason to allow multiple hooks is for add-on packages to be able to add their processing without fear of wiping out any existing hook functions. Because of the possibilities for confusion, you should take great care when using multiple hook functions.

Notes on Events 14-17 and 2

The actions caused by these events potentially affect multiple subwindows.

If you kill a subwindow, the root window's hook function(s) receives a subwindowKill event for that subwindow and any child subwindows.

If you kill a root window, the root window's hook function(s) receives a subwindowKill event for each child subwindow, and then the root window's hook function(s) receive a kill event.

Likewise, hiding and showing windows can result in subwindows being hidden or shown. In each case, the window hook function receives a hide or show event for each affected window or subwindow.

The winName member of WMWinHookStruct will be set to the full subwindow path of the subwindow that is affected.

Exterior subwindows are a special case because they are subwindows, but you can attach a hook function to an exterior subwindow. The hook function attached to the root window does not receive events affecting exterior subwindows. To handle subwindowKill, hide, or show events when an exterior subwindow is killed, hidden, or shown as a result of killing, hiding, or showing its parent window, you must have a hook function attached to the exterior subwindow.

As a further subtlety, the hook function(s) attached to an exterior subwindow will receive a subwindowKill event if the exterior subwindow is killed as a result of killing the parent window. But it will receive a regular kill event if it is killed directly. Normal subwindows always receive only subwindowKill events.

The kill-related events are sent in this order when a window or subwindow is killed:

1. A killVote event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed.
2. If the window is not a subwindow and wasn't created with /K=k the standard window close dialog appears. If the close is cancelled, the window is not killed, the window will receive an activate event when the dialog is dismissed, and no further events are generated. Otherwise, proceed to step 3.
- 3) If the window being killed has subwindows, starting from the bottom-most subwindow and working back toward the window being killed:
 - 3a. If the subwindow is a graph or panel, action procedures for controls contained in the subwindow are called with event -1, "control being killed".
 - 3b. The root window's hook function(s) receive a subwindowKill event for the subwindow. If any hook function returns 1, no further subwindow hook events or control being killed events are sent, but the window killing process continues.Steps 3a and 3b are repeated for each subwindow until the window or subwindow being killed is reached.
4. If the killed window is a root window, a kill event is sent to the root window's hook function(s). If any hook function returns 2, no further events are generated and the window is not killed. This method of preventing a window from closing is to be avoided: use the killVote event or the window-equivalent of NewPanel/K=2.

There are several ways to prevent a window being killed. You might want to do this in order to enforce use of a Done or Do It button, or to prevent killing a control panel while some hardware action is taking place.

The best method is to use /K=2 when creating the window (see **Display** or **NewPanel**). Then the only way to kill the window is via the DoWindow/K command, or KillWindow command. In general, you would provide a button that kills the window after checking for any conditions that would prevent it.

The KillVote event is more flexible but harder to use. It gives your code a chance to decide whether or not killing is allowed. This means the user can close and kill the window with the window close box when it is allowed.

Returning 2 for the window kill event is not recommended. If you have old code that uses this method, we strongly recommend changing it to return 2 for the killVote event. New code should never return 2 for the kill event.

Events 14-17 were added to Igor Pro version 6.02.

Example

Following is an example using a named hook to set the cursor as the mouse is moved horizontally across the bottom half of the window:

```
static constant kUHC_mousemoved=4
Function MyWinHook(s)
    STRUCT WMWinHookStruct &s
    Variable rval= 0
    switch(s.eventCode)
        case kUHC_mousemoved:
            if( s.mouseLoc.v > ((s.winRect.top+s.winRect.bottom)/2) )
                s.doSetCursor= 1
    s.cursorCode= round(27*(s.mouseLoc.h - s.winRect.left)/(s.winRect.right-s.winRect.left))
                rval= 1 // we have taken over this event
            endif
            break
    EndSwitch
    return rval
End
Function test()
    Make/O jack=x
    Display jack
    SetWindow kwTopWin, hook(testhook)= MyWinHook
End
```

This window hook invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for a graph, preventing Igor from performing the usual Copy.

```
Display myData
SetWindow kwTopWin hook=CopyIsExportHook
Function CopyIsExportHook(infoStr)
    string infoStr
    string event= StringByKey("EVENT", infoStr)
```

```

string win= StringByKey("WINDOW",infoStr)
variable handledIt= 0
strswitch(event)
  case "menu":
    String menuName= StringByKey("MENUNAME", infoStr)
    String itemName= StringByKey("MENUITEM", infoStr)
    if( CmpStr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0 )
      DoIgorMenu "Edit", "Export Graphics"      // dialog instead
      handledIt= 1
    endif
    break
endswitch
return handledIt
End

```

This example uses a window hook and button action procedure to implement a panel dialog with a Done button such that the panel can't be closed by clicking the panel's close widget, but can be closed by the Done button's action procedure:

```

Proc ShowDialog()
  PauseUpdate; Silent 1      // building window...
  NewPanel/N=Dialog/W=(225,105,525,305) as "Dialog"
  Button done,pos={119,150},size={50,20},title="Done"
  Button done,proc=DialogDoneButtonProc
  TitleBox warning,pos={131,83},size={20,20},title=""
  TitleBox warning,anchor=MC,fColor=(65535,16385,16385)
  SetWindow Dialog hook(dlog)=DialogHook, hookevents=2
EndMacro

Function DialogHook(s)
  STRUCT WMWinHookStruct &s
  Variable statusCode= 0

  strswitch( s.eventName )
  case "killVote":
    TitleBox warning win=$s.winName, title="Press the Done button!"
    Beep
    statusCode=2      // prevent panel from being killed.
    break
  case "mousemoved":
    // to reset the warning
    TitleBox warning win=$s.winName, title=""
    break
  endswitch
  return statusCode
End

Function DialogDoneButtonProc(ba) : ButtonControl
  STRUCT WMButtonAction &ba
  switch( ba.eventCode )
  case 2:
    // mouse up turn off the named window hook
    SetWindow $ba.win hook(dlog)=""
    // kill the window AFTER this routine returns
    Execute/P/Q/Z "DoWindow/K "+ba.win      // kill the window AFTER this routine returns
    break
  endswitch
  return 0
End

```

The **GetWindow**, **SetIgorHook**, and **SetIgorMenuMode** operations and **AxisValFromPixel**, **NumberByKey**, **PopupContextualMenu**, and **TraceFromPixel** functions. The **GetUserData** operation for retrieving named user data.

ShowIgorMenus

ShowIgorMenus [*MenuNameStr* [, *MenuNameStr*] ...

The ShowIgorMenus operation shows the named built-in menus or, if none are explicitly named, shows all built-in menus in the menu bar.

User-defined menus attached to built-in menus are also affected by this operation.

Parameters

MenuNameStr The name of an Igor menu, like "File", "Data", or "Graph".

ShowInfo

Details

See **HideIgorMenus** for details.

See Also

Chapter IV-5, **User-Defined Menus**.

The **HideIgorMenus**, **DoIgorMenu**, and **SetIgorMenuMode** operations.

ShowInfo

ShowInfo [/W=*winName*]

The ShowInfo operation puts an information box on the target or named graph. The information box contains cursors and readouts of values associated with waves in the graph.

Flags

/W=*winName* Displays info box in the named window.

See Also

Info Box and Cursors on page II-265.

The **HideInfo** operation.

ShowTools

ShowTools [/A/W=*winName*] [*toolName*]

The ShowTools operation puts a tool palette for drawing along the left hand side of the target or named graph or control panel, and optionally activates the named tool.

Flags

/A Sizes window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=*winName* Shows tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

Parameters

If you specify a *toolName* (which can be one of: normal, arrow, text, line, rect, rrect, oval, or poly) the named tool is activated. Specifying the “normal” tool has the same effect as issuing the GraphNormal command for a graph that has the drawing tools selected.

Details

The activated tool is not highlighted until the top graph or control panel becomes the topmost (activated) window. Use DoWindow/F to bring a window to the top (or “front”).

See Also

The **DoWindow**, **GraphNormal**, **GraphWaveDraw**, **GraphWaveEdit**, and **HideTools** operations.

sign

sign(*num*)

The sign function returns -1 if *num* is negative or 1 if it is not negative.

Silent

Silent *num*

The Silent operation enables or disables the display of macro commands in the command line as they are executed.

Parameters

If *num* is one, the display of macro commands is disabled. If *num* is zero, it is enabled.

When executed from the command line, “Silent 100” activates a compatibility mode that can run legacy macro code containing old-style comments, which use | instead of //, without causing errors. To exit this mode, execute “Silent 101” on the command line. Also see **Comments** on page IV-2.

If you create procedure files for use by others and you want to use the new logic operations such as || that require that Silent 101 be in effect, then you can specify

`#pragma rtGlobals=2`
in place of the normal `rtGlobals=1`.

If your procedure file is included in an experiment running in compatibility mode (Silent 100) then an alert dialog will allow the user to switch the experiment to the new syntax. However, keep in mind that when the procedures are recompiled in the new mode, the user's other procedures may not compile due to obsolete use of the vertical bar (|) as a comment character.

Details

Macros run faster if this display is disabled. If Silent is used in a macro its effect ends when the macro ends.

This has no effect in user-defined functions. During execution of a user-defined function, Igor does not display anything in the command line.

Commands sent to Igor Pro from another program via PPC or Apple events are normally logged into the history area. You can turn off the logging of these commands with the Silent operation. See also **The Silent Option** on page IV-84.

See Also

The **PauseUpdate** operation and `rtGlobals`.

sin

sin(*angle*)

The sin function returns the sine of *angle* which is in radians. In complex expressions, *angle* is complex, and `sin(angle)` returns a complex value.

sinc

sinc(*num*)

The sinc function returns `sin(num)/num`. The sinc function returns 1.0 when *num* is zero. *num* must be real.

sinh

sinh(*num*)

The sinh function returns the hyperbolic sine of *num*. In complex expressions, *num* is complex, and `sinh(num)` returns a complex value.

Sleep

Sleep [*flags*] *timeSpec*

The Sleep operation puts Igor to sleep for a while. After the while is up, Igor continues execution. You could use this, for example, to print a graph late at night, when the load on your printer is light.

Parameters

The format of *timeSpec* depends on which flags, if any, are present.

If no flags are present, then *timeSpec* is in *hh:mm:ss* format and specifies the number of elapsed hours, minutes and seconds to sleep.

Flags

/A *timeSpec* is an absolute time in 24 hour format (e.g., 16:00:00).

/A/W Wait until tomorrow if absolute time has passed.

/B Stop sleeping if the user clicks the mouse button.

/C=*cursor* Controls what kind of cursor to display during sleep.

cursor=-1: No cursor change.

cursor=0: Hour glass (default).

cursor=1: Arrow.

cursor=2: "Click".

cursor=<any other value>: watch.

/Q Continue executing the procedure containing the Sleep operation even if Command-period (Macintosh) or Ctrl+Break (Windows) was pressed.

Slider

/S *timeSpec* is a numeric expression in seconds.
/T *timeSpec* is a numeric expression in ticks (about 1/60 of a second).

Details

The Sleep operation does *not* let the user choose menus, move cursors, run procedures, draw in graphs, or do any other interactive task.

Normally *timeSpec* specifies an amount of elapsed time. If the */A* flag is present, then *timeSpec* is an absolute time when sleep is to end. If the specified absolute time has already passed, no sleep occurs unless you also use */W*, which makes it wait until tomorrow.

If you specify time in hh:mm:ss format, you can also specify the time indirectly through a string variable. See the examples.

You can end sleep by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*). Normally when you do this, it aborts any procedure that is running. However, if you use the */Q* flag, the procedure continues running normally.

Examples

These examples assume the current time is 4 pm:

```
Sleep 00:01:30           // sleeps for 1 minute, 30 seconds
Sleep/A 23:30:00         // sleeps until 11:30 PM
Sleep/A 03:00:00         // doesn't sleep at all because time is past
Sleep/A/W 03:00:00       // sleeps until 3 AM tomorrow
String str1= "03:00:00"  // put wakeup call time in string
Sleep/A/W $str1           // sleeps until 3 AM tomorrow
Sleep/B/C=2/S/Q 60       // sleep 60 seconds, or until user clicks,
                        // and keep going (don't abort)
```

Slider

Slider [*/Z*] **controlName** [*key* [= *value*]][, *key* [= *value*]]...

The Slider operation creates or modifies a Slider control in the target window.

A Slider control sets or displays a single numeric value. The user can adjust the value by dragging a thumb along the length of the Slider.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the Slider control to be created or changed.

key is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of *default*, *native*, or *os9*.

platform can be one of *Mac*, *Win*, or *All*.

Note: The Slider control reverts to *os9* appearance on Macintosh if *thumbColor* isn't the default blue (0,0,65535).

See **Button** and **DefaultGuiControls** for more appearance details.

disable=*d*

Sets user editability of the control.

d=0: Normal.

d=1: Hide.

d=2: Draw in gray state; disable control action.

font="*fontName* "

Sets the font used to display the tick labels, e.g., font="Helvetica".

fsiz=*s*

Sets the size of the type for tick mark labels.

help={*helpStr*}

Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, the help appears if you turn Igor Tips on. On Windows, the help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.

<code>limits={low,high,inc}</code>	<i>low</i> sets left or bottom value, <i>high</i> sets right or top value. Use <i>inc</i> =0 for continuous or use desired increment between stops.
<code>live=l</code>	<i>l</i> =0: Update only after mouse is released. <i>l</i> =1: Update as slider moves (default).
<code>noproc</code>	Specifies that no procedure is to execute when the control's value is changed.
<code>pos={left,top}</code>	Sets position of control in pixels.
<code>proc=procName</code>	Specifies the procedure to execute when the control's thumb is moved by the user.
<code>rename=newName</code>	Gives control a new name.
<code>side=s</code>	<i>s</i> =0: Thumb is blunt. <i>s</i> =1: Thumb points right or down (default). <i>s</i> =2: Thumb points up or left.
<code>size={width,height}</code>	Sets width or height of control in pixels. <i>height</i> is ignored if <i>vert</i> =0 and <i>width</i> is ignored if <i>vert</i> =1.
<code>thumbColor=(r,g,b)</code>	Sets dominant foreground color of thumb. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Only the hue and saturation are used. Therefore (0,1000,0) is the same tint of green as (0,10000,0).
<code>ticks=t</code>	<i>t</i> =0: No ticks. <i>t</i> =1: Number of ticks is calculated from limits (no ticks drawn if calculated value is less than 2 or greater than 100). Default value. <i>t</i> >1: <i>t</i> is the number of ticks distributed between the start and stop position. Ticks are labeled using the same automatic algorithm used for graph axes. Use negative tick values to force ticks to not be labeled. Ticks are shown on the side specified by the <i>side</i> keyword and are not drawn if <i>side</i> =0.
<code>tkLblRot= deg</code>	Rotates tick labels in multiples of 90 degrees only.
<code>userdata(UDName)=UDStr</code>	Sets the unnamed user data to <i>UDStr</i> . Use the optional (<i>UDName</i>) to specify a named user data to create.
<code>userdata(UDName)+=UDStr</code>	Appends <i>UDStr</i> to the current unnamed user data. Use the optional (<i>UDName</i>) to append to the named <i>UDStr</i> .
<code>userTicks={tvWave,tlblWave}</code>	User-defined tick positions and labels. <i>tvWave</i> contains the tick positions, and text wave <i>tlblWave</i> contains the labels. See ModifyGraph (axes) userticks for more info. Overrides normal ticking specified by <i>ticks</i> keyword.
<code>value=v</code>	<i>v</i> is the new value for the Slider.
<code>variable= var</code>	Sets the variable (<i>var</i>) that the slider will update. Unlike <code>SetVariable</code> controls, it is not necessary to connect a Slider to a variable — you can get a Slider's value using the ControlInfo operation.
<code>vert=v</code>	Set vertical (<i>v</i> =1; default) or horizontal (<i>v</i> =0) orientation of the slider.
<code>win=winName</code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The format of the action procedure (set by the *proc* keyword) that will be called as the user drags the Slider's thumb is:

```
Function MySliderProc(name, value, event)
    String name           // name of this slider control
    Variable value        // value of slider
```

```

Variable event          // bit field:bit 0:value set; 1:mouse down,
                        // 2:mouse up, 3:mouse moved
return 0                // other return values reserved
End

```

If you use negative ticks to suppress automatic labeling, you can label tick marks using drawing tools (panels only).

The action procedure for a Slider control can also use a predefined structure `WMSliderAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a Slider control, otherwise it will use the old-style method.

A Slider action procedure using a structure has the format:

```

Function newActionProcName(S_Struct)
    STRUCT WMSliderAction &S_Struct
    ...
End

```

For a Slider control, the `WMSliderAction` structure has members as described in the following table:

WMSliderAction Structure Members

Member	Description
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.
<code>STRUCT Rect winRect</code>	Local coordinates of host window.
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.
<code>STRUCT Point mouseLoc</code>	Mouse location.
<code>Int32 eventCode</code>	Event that caused the procedure to execute. Sets bit fields: bit 0: value set. bit 1: mouse down. bit 2: mouse up. bit 3: mouse moved. When the control is about to be killed, <code>eventCode</code> is set to -1.
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of MODIFIERS: flags for SetWindow under Unnamed Hooks on page V-505.
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.
<code>double curval</code>	Value of slider.

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

Examples

```

Function SliderExample()
    NewPanel /W=(150,50,501,285)
    Variable/G var1
    Execute "ModifyPanel cbRGB=(56797,56797,56797)"
    SetVariable setvar0,pos={141,18},size={122,17},limits={-Inf,Inf,1},value=var1
    Slider foo,pos={26,31},size={62,143},limits={-5,10,1},variable=var1
    Slider foo2,pos={173,161},size={150,53}
    Slider foo2,limits={-5,10,1},variable=var1,vert=0,thumbColor=(0,1000,0)
    Slider foo3,pos={80,31},size={62,143}
    Slider foo3,limits={-5,10,1},variable=var1,side=2,thumbColor=(1000,1000,0)
    Slider foo4,pos={173,59},size={150,13}
    Slider foo4,limits={-5,10,1},variable=var1,side=0,vert=0
    Slider foo4,thumbColor=(1000,1000,1000)
    Slider foo5,pos={173,90},size={150,53}

```

```
Slider foo5,limits={-5,10,1},variable= var1,side=2,vert=0
Slider foo5,ticks=5,thumbColor=(500,1000,1000)
End
```

See Also

Slow

Slow ticks

The Slow operation slows down execution of macros for debugging purposes.

Parameters

ticks is in units of 1/60 second. A value of 30 is about right to allow you to read the macro command lines as they are executed. **Slow 0** resumes normal macro execution.

Details

This has no effect in user-defined functions.

Smooth

Smooth [*flags*] *num*, *waveName* [, *waveName*...]

The Smooth operation smooths the named waves using binomial (Gaussian) smoothing, boxcar (sliding average) smoothing, Savitzky-Golay (polynomial) smoothing, or running-median filtering.

Parameters

num is the number of smoothing operations to be applied for binomial smoothing or the number of points in the smoothing window for boxcar, Savitzky-Golay, and running-median smoothing.

Each *waveName* is smoothed in-place, overwriting the values with the smoothed result. *waveName* may be a floating point or integer wave.

If *waveName* contains NaNs, the results are undefined. (The **Loess** operation and the Interpolate XOP can fill in NaNs).

Flags

- /B [=b] Invokes boxcar smoothing algorithm. If given, *b* specifies the number of passes to use when smoothing the data with smoothing factor *num* (box width). The number of passes can be any value between 1 and 32767.
- /DIM=*d* Specifies the wave dimension to smooth.
d=-1: Treats entire wave as 1D (default).
For *d*=0, 1,..., operates along rows, columns, etc.
- /E=*endEffect* Determines how to handle the ends of the wave (*w*) when fabricating missing neighbor values.
endEffect=0: Bounce method (default). Uses *w*[*i*] in place of the missing *w*[-*i*] and *w*[*n*-*i*] in place of the missing *w*[*n*+*i*].
endEffect=1: Wrap method. Uses *w*[*n*-*i*] in place of the missing *w*[-*i*] and vice versa.
endEffect=2: Zero method. Uses 0 for any missing value.
endEffect=3: Fill method. Uses *w*[0] in place of the missing *w*[-*i*] and *w*[*n*] in place of the missing *w*[*n*+*i*].
- /EVEN [=evenAllowed] Specifies the smoothing increment for boxcar smoothing (/B). Values are:
0: Increments even values of *num* to the next odd value. Default when /EVEN omitted.
1: Uses even values of *num* for boxcar smoothing despite the half-sample shifting this introduces in the smoothed output (prior to version 6, this shift was prevented). Same as /EVEN alone.
- /F [=f] Selects the boxcar or multipass binomial smoothing method:
f=0: Slow, but accurate, method (default).

	<i>f</i> =1: Fast method. Same as /F alone.
/M= <i>threshold</i>	Invokes running-median smoothing and specifies an absolute numeric threshold used to optionally replace “outliers”. Points that differ from the central median by an amount exceeding <i>threshold</i> are replaced, either with the <i>replacement</i> value specified by /R, or otherwise with the median value. Special <i>threshold</i> values are: 0: Replace all values with running-median values or the <i>replacement</i> value. (NaN): Replace only NaN input values with running-median values or the <i>replacement</i> value. The smoothing factor <i>num</i> is the number of points in the smoothing window used to compute each median.
/R= <i>replacement</i>	Specifies the value that replaces input values that exceed the central median by <i>threshold</i> (requires /M). <i>threshold</i> can be any value (including NaN or ±Inf if <i>waveName</i> is floating point).
/S= <i>sgOrder</i>	Invokes Savitzky-Golay smoothing algorithm and specifies the smoothing order. <i>sgOrder</i> must be either 2 or 4.

Details

For binomial smoothing, use no flags (other than /DIM, /E, and /F) and a *num* value from 1 to 32767.

The binomial smooth algorithm automatically switches to a nearly equivalent (but *much* faster) multipass box smooth at smooth factor of 50. The original algorithm can be used when you set global variable `V_doOrigBinomSmooth=1` in the root data folder. To get the pre-Igor Pro 5pX behavior you also need to add the /F flag.

The /F (fast boxcar smoothing) algorithm creates small errors when the data has a large offset. For some data sets you may want to subtract the mean of the data before smoothing and add it back in afterwards.

The binomial smoothing algorithm does not detect and ignore NaNs in the input data.

For boxcar smoothing, use the /B flag and a *num* value from 1 to 32767.

For *num* < 2, no smoothing is done.

If *num* is even and /EVEN is not specified, *num* is incremented to the next (odd) integer.

If *num* is even and /EVEN is specified, each smoothed output is formed from one more previous value than future values.

The boxcar smoothing algorithm detects and ignores NaNs in the input data. If *num* is less than the number of NaNs near the output point, then the result is NaN. Otherwise the average of the non-NaN neighboring points is used to compute the smoothed result.

For Savitzky-Golay smoothing, use the /S flag and an odd *num* value from 5 to 25. An even value for *num* returns an error. If *sgOrder*=4, then *num*=5 gives no smoothing at all so *num* should be at least 7.

The Savitzky-Golay smoothing algorithm does not detect and ignore NaNs in the input data.

For running-median smoothing, use the /M flag and a *num* value from 1 to 32767. If *num* is even, the median is the average of the two middle values. When *num* is 1, no smoothing is done

Use /M=0 to replace all values with the median over the smoothing window or use /M=*threshold*/R=(NaN) to replace outliers with NaNs.

Use /M=(NaN) to replace only NaN input values with the running-median values or the *replacement* value.

The running-median smoothing algorithm detects and ignores NaNs in the input data. If *num* is less than the number of NaNs near the output point, then the result is NaN. Otherwise the median of the non-NaN neighboring points is used to compute the smoothed result.

These smoothing algorithms compute the output value for a given point using each point's neighbors. Except for running-median smoothing, each algorithm combines neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors so some method for fabricating neighbor values must be implemented. The /E flag specifies the method.

The running-median filter, however, ignores /E. At each end of the data fewer values are included in the median calculation, so that values “beyond” the end of data are not needed.

The first output value is the median of `wave[0, floor((num-1)/2)]`. For example, if *num* = 7, then the first output value is the median of `wave[0]`, `wave[1]`, `wave[2]`, and `wave[3]`. Because that is an even number

of points, the median is the average of the two middle values. Continuing the example, if the values were 3, 1, 7, and 5, the two middle values are 3 and 5. The computed median would be $(3+5)/2=4$.

Examples

Box smoothing example:

```
Make/N=100 wv; Display wv
wv=gnoise(1)
Smooth/B/E=3 3,wv      // output[p] = average of wv[p-1], wv[p] and wv[p+1]
                        // /E=3 causes wv[0] = (w[0]+w[0]+w[1])/3
                        // and wv[n-1] = (w[n-2]+w[n-1]+w[n-1])/3
```

Demonstrate the impulse response of Savitzky-Golay Smoothing:

```
Make/O/N=100 wv
wv= p==50      // 1 at center of wave, 0 elsewhere; an impulse
SetScale/P x, 0, 1/1000, "s", wv      // 1000 Hz sampling rate
Smooth/S=2 5,wv
Display wv
ModifyGraph mode=8,marker=19
FFT/MAG/DEST=fftMag wv
Display fftMag
```

Replace NaN with median:

```
Make/O/N=100 data= enoise(1)>.9 ? NaN : sin(x/8)      // signal with NaNs
Duplicate/O data, dataMedian
Smooth2/M=(NaN) 5, dataMedian      // replace (only) NaNs with 5-point median
```

See Also

See the **Loess**, **MatrixConvolve**, and **MatrixFilter** operations for true 2D smoothing.

The **FilterFIR**, **FilterIIR**, and **Loess** operations; the Interpolate XOP.

Also see the Smooth Operation Responses example experiment.

SmoothCustom

SmoothCustom [**/E=endEffect**] *coefsWaveName*, *waveName* [, *waveName*]...

Note: SmoothCustom is obsolete. Use the **FilterFIR** operation instead. For multidimensional data use the **MatrixConvolve** or **MatrixFilter** operations.

The SmoothCustom operation smooths waves by convolving them with *coefsWaveName*.

Parameters

coefsWaveName must be single or double floating point, must not be one of the destination *waveNames*, must not be complex.

waveName is a numeric destination wave that is overwritten by the convolution of itself and *coefsWaveName*.

Flags

/E=endEffect End effect method, a value between 0 and 3. See the **Smooth** operation for a description of the */E* flag.

Details

The convolution is in the time domain. That is, the FFT is not employed. For this reason the length of *coefsWaveName* should be small or small in comparison to the destination waves.

SmoothCustom presumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The “middle” point number = $\text{trunc}(\text{numpts}(\text{coefsWaveName}-1)/2)$. *coefsWaveName* usually contains the two-sided impulse response of a filter, and contains an odd number of points. This is the type of wave created by FilterFIR.

SmoothCustom ignores the X scaling of all the waves.

The SmoothCustom operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

Sort

Sort [**/A/C/R**] *sortKeyWaves*, *sortedWaveName* [, *sortedWaveName*]...

The Sort operation sorts the *sortedWaveNames* by rearranging their Y values to put the data values of *sortKeyWaves* in order.

Parameters

sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

All waves must be of the same length.

The *sortKeyWaves* must not be complex.

Flags

/A Alphanumeric sort. When *sortKeyWaves* includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”. Use */A* to sort the number portion numerically, so that “wave9” is sorted before “wave10”.

/C Case-sensitive sort. When *sortKeyWaves* includes text waves, the sort is case-insensitive unless you use the */C* flag to make it case-sensitive.

/R Reversed sort; sort from largest to smallest.

Details

sortKeyWaves are not actually sorted unless they also appear in the list of destination waves.

The sort algorithm does not maintain the relative position of items with the same key value.

Examples

```
Sort/R myWave,myWave           // sorts myWave in decreasing order
Sort xWave,xWave,yWave         // sorts x wave in increasing order,
                                // corresponding yWave values follow.
Make/O/T myWave={"1st","2nd","3rd","4th"}
Make/O key1={2,1,1,1}          // places 2nd, 3rd, 4th before 1st.
Make/O key2={0,1,3,2}          // arranges 2nd, 3rd, 4th as 2nd, 4th, 3rd.
Sort {key1,key2},myWave         // sorts myWave in increasing order by key1.
                                // For equal key1 values, sorted by key2.
```

```

                                // Result is myWave={"2nd","4th","3rd","1st"}
Make/O/T tw={"w1","w10","w9","w-2.1"}
Sort/A tw,tw // sorts tw in increasing number-aware order:
              // Result is tw={"w-2.1","w1","w9","w10"}

```

See Also

The **MakeIndex**, **IndexSort**, and **Reverse** operations. See **Sorting** on page III-132.

SortList

SortList(listStr [, listSepStr [, options]])

The SortList function returns *listStr* after sorting it according to the default or *listSepStr* and *optionsStr* parameters. *listStr* should contain items separated by the *listSepStr* character, such as "the first item;second item;".

Use SortList to sort the items in a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **WaveList**, or a line of text from a delimited text file.

listSepStr and *options* are optional; their defaults are ";" and 0 (alphabetic sort), respectively.

Details

listStr is treated as if it ends with a *listSepStr* even if it doesn't. The returned list will always have an ending *listSepStr* character.

Only the first character of *listSepStr* is used. If *listSepStr* is "" then the default of ";" is used.

options is a literal number which controls the sorting method. *options* is one of:

- 0: Default sort (ascending case-sensitive alphabetic ASCII sort).
- 1: Descending sort.
- 2: Numeric sort.
- 4: Case-insensitive sort.
- 8: Case-sensitive alphanumeric sort using system script.
- 16: Case-insensitive alphanumeric sort that sorts wave0 and wave9 before wave10.

or a bitwise combination of the above with the following restriction: only one of 2, 4, 8, or 16 may be specified. The legal values are thus 0, 1, 2, 3, 4, 5, 8, 9, 16, and 17. Other values will produce undefined sorting criteria.

Examples

```

// alphabetic sorts
Print SortList("b;c;a;") // prints "a;b;c;"
Print SortList("you,me,i", ",", 4) // prints "i,me,you,"
Print SortList("9,93,91,33,15,3", ",", 0) // prints "15,3,33,9,91,93,"
Print SortList("Zx;abc;All;", ";", 0) // prints "All;Zx;abc;"
Print SortList("Zx;abc;All;", ";", 8) // prints "abc;All;Zx;"
Print SortList("w9;w10;w02;", ";", 16) // prints "w02;w9;w10;"

// numeric sorts
Print SortList("9,93,91,33,15,3", ",", 2) // prints "3,9,15,33,91,93,"
// (reversed)
Print SortList("9,93,91,33,15,3", ",", 3) // prints "93,91,33,15,9,3,"

```

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

SoundInRecord

SoundInRecord [/Z] wave

The SoundInRecord operation records audio input at the sample rate obtained from the wave's X scaling and for the number of points determined by the length of the wave. The recording is done synchronously.

Number type of wave must be 8-bit integer or 16-bit integer. The sound input driver is told to record at that number of bits. If 16 bit recording is not supported by the hardware, the sound driver may return an error but more likely will simply translate 8 to 16.

To record in stereo, provide a 2 column wave. (The software is designed to handle any number of channels but has not been tested on more than 2.)

SoundInSet

Flags

/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details

SoundInRecord requires a computer with sound inputs. Several sample experiments using sound input can be found in your Igor Pro Folder in the Examples folder.

Note: Mac OS X (at least up to 10.3) appears to require stereo and 16 bits.

See Also

The **SoundInSet**, **SoundInStartChart**, and **SoundInStatus** operations.

SoundInSet

SoundInSet [/Z] [gain=g, agc=a]

The SoundInSet operation is used to setup the input device for recording.

Parameters

SoundInSet can accept multiple *keyword =value* parameters on one line.

agc=a Turns automatic gain control mode on (a=1) or off (a=0). Will generate an error if device does not support setting agc. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

Windows: This is not supported and V_SoundInAGC from the SoundInStatus command always returns -1.

gain=g Sets input gain, 0 is lowest gain and 1 is highest. Will generate an error if device does not support setting gain. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

Windows: SoundInSet attempts to adjust the master gain of the sound input device but not all sound cards have a master gain. If V_SoundInGain from the SoundInStatus command returns -1, you will have to use your sound card software to adjust the input gain for the particular input source you are using. On some cards there are separate line-in and microphone-in sources.

Flags

/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details

SoundInSet requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

See Also

The **SoundInRecord**, **SoundInStartChart**, and **SoundInStatus** operations.

SoundInStartChart

SoundInStartChart [/Z] *buffersize* , *destFIFOname*

The SoundInStartChart operation starts audio data acquisition into the given FIFO.

Parameters

buffersize is the number of bytes to allocate for the interrupt time buffer which then feeds into the given Igor named FIFO *destFIFOname*. The FIFO must be set up with the correct number of channels and with either 16- or 8-bit integer number type. The sample rate is read from the FIFO also, so that also needs to be correct.

Flags

/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details

SoundInStartChart requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

Note: Mac OS X (at least up to 10.3) appears to require stereo and 16 bits.

See Also

The **SoundInRecord**, **SoundInSet**, **SoundInStatus** and **SoundInStopChart** operations, and **FIFOs and Charts** on page IV-208.

SoundInStatus

SoundInStatus

The SoundInStatus operation creates and sets a set of variables and strings with information about the current sound input device. The variable V_flag is set to an error code and will be zero if the device is available. If not then none of the following are valid.

Variables	Contents
S_SoundInName	String with name of device.
V_SoundInAGC	Automatic gain control on or off (1 or 0). This is an optional item and if the current device does not support AGC then V_SoundInAGC will be set to -1.
V_SoundInChansAv	Available number of channels (e.g., 1 for mono, 2 for stereo).
V_SoundInGain	Current input gain. Ranges from 0 (lowest) to 1. This is an optional item and if the current device does not support gain then V_SoundInGain will be set to -1.
V_SoundInSampSize	Bits set depending on number of bits in a sample available: Bit 0 set if can do 8 bits, bit 1 set if can do 16 bits.
W_SoundInRates	Wave containing sample rate info: if point zero contains zero then points 1 and 2 contain the lower and upper limits of a continuous range else point zero contains the number of discrete rates which follow in the wave. The usual rates are 11025, 22050 and 44100 Hz.

See Also

The **SoundInRecord**, **SoundInSet**, and **SoundInStartChart** operations.

SoundInStopChart

SoundInStopChart [/Z]

The SoundInStopChart operation stops audio data acquisition started by SoundInStartChart.

Flags

/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details

SoundInStopChart requires a computer equipped with sound input hardware.

Audio data acquisition also stops automatically when an experiment is closed.

See Also

The **SoundInStartChart** and **SoundInStatus** operations.

SpecialCharacterInfo

SpecialCharacterInfo(*notebookNameStr*, *specialCharacterNameStr*, *whichStr*)

The SpecialCharacterInfo function returns a string containing information about the named special character in the named notebook window.

Parameters

notebookNameStr is the name of a notebook or "" for the top visible notebook.

specialCharacterNameStr is the name of a special character in the notebook.

whichStr identifies the information item you want. Because SpecialCharacterInfo can return several items that may contain semicolons, it does not return a semicolon-separated keyword-value list like other info functions. Instead it returns just one item as specified by *whichStr*.

Details

Here are the supported values for *whichStr*.

SpecialCharacterInfo

Keyword	Returned Action Information	
FRAME	FRAME	Kind
	0	None
	1	Single
	2	Double
	3	Triple
	4	Shadow
LOC	Paragraph and character position (e.g., 1,3).	
SCALING	Horizontal and vertical scaling in units of one tenth of a percent (e.g., 1000,1000).	
TYPE	Special character type is: Picture, Graph, Table, Layout, Action, ShortDate, LongDate, AbbreviatedDate, Time, Page, TotalPages, or WindowTitle.	

The remaining keywords apply to notebook action characters only. If the specified special character is not a notebook action character, " " is returned.

Keyword	Returned Action Information														
BGRGB	Background color in RGB format (e.g., 65535,65534,49151).														
COMMANDS	Command string.														
ENABLEBGRGB	1 if the action’s background color is enabled, 0 if not.														
HELPTEXT	Help text string.														
IGNOREERRORS	0 or 1.														
LINKSTYLE	0 or 1.														
PADDING	The value of the left, right, top, bottom and internal padding properties, in that order (.e.g, 4,4,4,4,8).														
PICTURE	1 if the action has a picture, 0 if not.														
PROCPICNAME	The name of the action Proc Picture or " " if none.														
QUIET	0 or 1.														
SHOWMODE	<table><tr><th>SHOWMODE</th><th>Displayed</th></tr><tr><td>1</td><td>Title only</td></tr><tr><td>2</td><td>Picture only</td></tr><tr><td>3</td><td>Picture below title</td></tr><tr><td>4</td><td>Picture above title</td></tr><tr><td>5</td><td>Picture to the left of title</td></tr><tr><td>6</td><td>Picture to the right of title</td></tr></table>	SHOWMODE	Displayed	1	Title only	2	Picture only	3	Picture below title	4	Picture above title	5	Picture to the left of title	6	Picture to the right of title
SHOWMODE	Displayed														
1	Title only														
2	Picture only														
3	Picture below title														
4	Picture above title														
5	Picture to the left of title														
6	Picture to the right of title														
TITLE	Title string.														

If *whichStr* is an unknown keyword, SpecialCharacterInfo returns " " but does not generate an error.

Examples

```
Function PrintSpecialCharacterInfo(notebookName, specialCharacterName)
    String notebookName, specialCharacterName
    String typeStr=SpecialCharacterInfo(notebookName, specialCharacterName, "TYPE")
    String locStr=SpecialCharacterInfo(notebookName, specialCharacterName, "LOC")
    Printf "TYPE: %s\r", typeStr
    Printf "LOC: %s\r", locStr
End
```

See Also

The **Notebook** and **NotebookAction** operations; the **SpecialCharacterList** function.

SpecialCharacterList

SpecialCharacterList(*notebookNameStr*, *separatorStr*, *mask*, *flags*)

The **SpecialCharacterList** function returns a string containing a list of names of special characters in a formatted text notebook.

Parameters

notebookNameStr is the name of a notebook or "" for the top visible notebook.

separatorStr should contain a single character, usually semicolon, to separate the names.

mask determines which types of special characters are included. *mask* is a bitwise parameter with values:

- 1: Pictures including graphs, tables and layouts.
- 2: Notebook actions.
- 4: All other special characters such as dates and times.

or a bitwise combination of the above for more than one type. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

flags is a bitwise parameter. Pass 0 to include all special characters or 1 to include only selected special characters. All other bits are reserved and should be passed as zero.

Details

Only formatted text notebooks have special characters. When called for a plain text notebook, **SpecialCharacterList** always returns "".

Examples

Print a list of all special characters in the top notebook:

```
Print SpecialCharacterList("", ";", -1, 0)
```

Prints a list of notebook action characters in Notebook0:

```
Print SpecialCharacterList("Notebook0", ";", 2, 0)
```

Print a list of selected notebook action characters in Notebook0:

```
Print SpecialCharacterList("Notebook0", ";", 2, 1)
```

See Also

The **Notebook** and **NotebookAction** operations; the **SpecialCharacterInfo** function.

SpecialDirPath

SpecialDirPath(*dirIDStr*, *domain*, *flags*, *createdir*)

The **SpecialDirPath** function returns a full path to a file system directory specified by *dirIDStr* and *domain*. It provides a programmer with a way to access directories of special interest, such as the preferences directory and the desktop directory.

The path returned always ends with a separator character which may be a colon, backslash, or forward slash depending on the operating system and the *flags* parameter.

SpecialDirPath depends on operating system behavior. The exact path returned depends on the locale, the operating system, the specific installation, the current user, and possibly other factors.

Parameters

dirIDStr is one of the following strings:

- | | |
|---------------|---|
| "Packages" | Place for advanced programmers to put preferences for their procedure packages. |
| "Documents" | The OS-defined place for users to put documents. |
| "Preferences" | The OS-defined place for applications to put preferences. |
| "Desktop" | The desktop. |
| "Temporary" | The OS-defined place for applications to put temporary files. |

domain permits discriminating between, for example, the preferences folder for all users versus the preferences folder for the current user. It is supported only for certain *dirIDStrs*. It is one of the following:

sphericalBessJ

- | | | |
|----|------------------|---|
| 0: | The current user | (recommended value for most purposes). |
| 1: | All users | (may generate an error or return the same path as 0). |
| 2: | System | (may generate an error or return the same path as 1). |

flags a bitwise parameter:

Bit 0: If set, the returned path is a native path (Macintosh-style on Mac OS 9, Unix-style on Mac OS X, Windows-style on Windows). If cleared, the returned path is a Macintosh-style path regardless of the current platform. In most cases you should set this bit to zero since Igor accepts Macintosh-style paths on all operating systems. You must set this bit to one if you are going to pass the path to an external script.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

createDir is 1 if you want the directory to be created if it does not exist or 0 if you do not want it to be created. This flag will not work if the current user does not have sufficient privileges to create the specified directory. In almost all cases it is not needed, you can't count on it, and you should pass 0.

Details

The *domain* parameter has no effect in most cases. In almost all cases you should pass 0 (current user) for this parameter. For values other than 0, SpecialDirPath might return an error which you must be prepared to handle.

In the event of an error, SpecialDirPath returns a NULL string and sets a runtime error code. You can check for an error like this:

```
String fullPath = SpecialDirPath("Packages", 0, 0, 0)
if (!(strlen(fullPath) > 0)) // strlen(NULL) returns NaN
    Print "SpecialDirPath returned error."
endif
```

Here is sample output from the SpecialDirPath function on three tested systems.

dirIDStr = "Packages", *domain* = 0

Mac OS 9 hd:System Folder:Preferences:WaveMetrics:Igor Pro 6:Packages:

Mac OS X hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro 6:Packages:

Windows 2000 C:Documents and Settings:<user>:Application Data:WaveMetrics:Igor Pro 6:Packages:

where <user> is the name of the current user. The preferences directory may be hidden by some operating systems.

Example

For an example using SpecialDirPath, see **Saving Package Preferences** on page IV-180.

sphericalBessJ

sphericalBessJ(*n*, *x* [, *accuracy*])

The sphericalBessJ function returns the spherical Bessel function of the first kind and order *n*.

$$j_n(x) = \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x).$$

For example:

$$j_0(x) = \frac{\sin(x)}{x} \quad j_1(x) = \frac{\sin(x)}{x^2} - \frac{\cos(x)}{x} \quad j_2(x) = \left(\frac{3}{x^3} - \frac{1}{x}\right) \sin(x) - \frac{3}{x^2} \cos(x).$$

Details

See the **bessI** function for details on accuracy and speed of execution.

The **sphericalBessJD** and **sphericalBessY** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

sphericalBessJD

sphericalBessJD(*n*, *x* [, *accuracy*])

The sphericalBessJD function returns the derivative of the spherical Bessel function of the first kind and order *n*.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **sphericalBessJ** and **sphericalBessY** functions.

sphericalBessY

sphericalBessY(*n*, *x* [, *accuracy*])

The sphericalBessY function returns the spherical Bessel function of the second kind and order *n*.

$$y_n(x) = \sqrt{\frac{\pi}{2x}} Y_{n+1/2}(x) \qquad y_0(x) = -\frac{\cos(x)}{x}$$
$$y_1(x) = -\frac{\cos(x)}{x^2} - \frac{\sin(x)}{x} \qquad y_2(x) = \left(\frac{1}{x} - \frac{3}{x^3}\right)\cos(x) - \frac{3}{x^2}\sin(x).$$

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **sphericalBessYD** and **sphericalBessJ** functions.

References

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

sphericalBessYD

sphericalBessYD(*n*, *x* [, *accuracy*])

The sphericalBessYD function returns the derivative of the spherical Bessel function of the second kind and order *n*.

Details

See the **bessI** function for details on accuracy and speed of execution.

See Also

The **sphericalBessJ** and **sphericalBessY** functions.

sphericalHarmonics

sphericalHarmonics(*L*, *M*, *q*, *f*)

The sphericalHarmonics function returns the complex-valued spherical harmonics

$$Y_L^M(\theta, \phi) = (-1)^M \sqrt{\frac{2L+1}{4\pi} \frac{(L-M)!}{(L+M)!}} P_L^M(\cos\theta) e^{iM\phi}$$

where $P_L^M(\cos\theta)$ is the associated Legendre function.

The **legendreA** function. The NumericalIntegrationDemo.pxp experiment.

References

Arfken, G., *Mathematical Methods for Physicists*, Academic Press, New York, 1985.

SphericalInterpolate

SphericalInterpolate *triangulationDataWave*, *dataPointsWave*, *newLocationsWave*

The SphericalInterpolate operation works in conjunction with the SphericalTriangulate operation to calculate interpolated values on a surface of a sphere. Given a set of $\{x_i, y_i, z_i\}$ points on the surface of a sphere with their associated values $\{v_i\}$, the SphericalTriangulate operation performs the Delaunay triangulation and creates an output that is used by the SphericalInterpolate operation to calculate values at any other point on the surface of a sphere. The interpolation calculation uses Voronoi polygons to weigh the contribution of the nearest neighbors to any given location on the sphere.

Parameters

triangulationDataWave is a 13 column wave that was created by the SphericalTriangulate operation.

dataPoints is a 4 column wave. The first 3 columns are the $\{x_i, y_i, z_i\}$ locations that were used to create the triangulation, and the last column corresponds to the $\{v_i\}$ values at the triangulation locations.

newLocationsWave is a 3 column wave that specifies the x, y, z locations on the sphere at which the interpolated values are calculated. Note that internally, each triplet is normalized to a point on the unit sphere before it is used in the interpolation.

Details

You will always need to use the SphericalTriangulate operation first to generate the *triangulationDataWave* input for this operation.

The result of the operation are put in the wave *W_SphericalInterpolation*.

See Also

The **SphericalTriangulate** operation.

SphericalTriangulate

SphericalTriangulate [/Z] *tripletWaveName*

The SphericalTriangulate operation triangulates an arbitrary XYZ triplet wave on a surface of a sphere.

It starts by normalizing the data to make sure that $\sqrt{x^2+y^2+z^2}=1$, and then proceeds to calculate the Delaunay triangulation.

Flags

/Z No error reporting.

Details

The result of the triangulation is the wave *M_SphericalTriangulation*. This 13 column wave is used in SphericalInterpolate to obtain the interpolated values.

See Also

The **SphericalInterpolate** operation.

SplitString

SplitString /E=*regExprStr* *str* [, *substring1* [, *substring2*,... *substringN*]]

The SplitString operation uses the regular expression *regExprStr* to split *str* into subpatterns. See **Subpatterns** on page IV-133 for details. Each matched subpattern is returned sequentially in the corresponding substring parameter.

Parameters

str is the input string to be split into subpatterns.

The *substring1...substringN* output parameters must be the names of existing string variables if you need to use the matched subpatterns. The first matched subpattern is returned in *substring1*, the second in *substring2*, etc.

Flags

/E=*regExprStr* Specifies the Perl-compatible regular expression string containing subpattern definition(s).

Details

regExprStr is a regular expression with successive subpattern definitions, such as shown in the examples. (Subpatterns are regular expressions within parentheses.)

For unmatched subpatterns, the corresponding substring is set to "". If you specify more substring parameters than subpatterns, the extra parameters are also set to "".

The number of matched subpatterns is returned in `V_flag`.

The part of *str* that matches *regExprStr* (often all of *str*) is stored in `S_value`.

Examples

```
// Split the output of the date() function:
Print date()
    Mon, May 2, 2005

String expr="([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"
String dayOfWeek, monthName, dayNumStr, yearStr

The **sscanf** and **Grep** operations. The **strsearch** and **str2num** functions.

sprintf

sprintf *stringName*, *formatStr* [, *parameter*]...

The **sprintf** operation is the same as **printf** except it prints the formatted output to the string variable *stringName* rather than to the history area.

Parameters

<i>formatStr</i>	See printf .
<i>parameter</i>	See printf .
<i>stringName</i>	Results are “printed” into the named string variable.

See Also

The **printf** operation for complete format and parameter descriptions and **Creating Formatted Text** on page IV-184.

sqrt

sqrt (*num*)

The **sqrt** function returns the square root of *num* or NaN if *num* is negative. In complex expressions, *num* is complex, and **sqrt**(*num*) returns a complex value.

sscanf

sscanf *scanStr*, *formatStr*, *var* [, *var*]

The **sscanf** operation is useful for parsing text that contains numeric or string data. It is based on the C **sscanf** function and provides a subset of the features available in C.

Here is a trivial example:

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

This skips the text "Value=" and the following space and then converts the text "1.234" (or whatever number appeared there) into a number and stores it in the local variable `v1`.

The `sscanf` operation sets the variable `V_flag` to the number of values read. You can use this as an initial check to see if the `scanStr` is consistent with your expectations.

Note: The `sscanf` operation is supported in user functions only. It is not available using the command line, using a macro, or using the Execute operation.

Parameters

`scanStr` contains the text to be parsed.

`formatStr` is a format string which describes how the parsing is to be done.

`formatStr` is followed by the names of one or more local numeric or string variables or NVARs (references to global numeric variables) or SVARs (references to global string variables), which are represented by `var` above.

`sscanf` can handle a maximum of 100 `var` parameters.

Details

The format string consists of the following:

- Normal text, which is anything other than a percent sign ("%") or white space.
- White space (spaces, tabs, linefeeds, carriage returns).
- A percent ("%") character, which is the start of a conversion specification.

The trivial example illustrates all three of these components.

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

`sscanf` attempts to match normal text in the format string to the identical normal text in the scan string. In the example, the text "Value=" in the format string skips the identical text in the scan string.

`sscanf` matches a single white space character in the format string to 0 or more white space characters in the scan string. In the example, the single space skips the single space in the scan string.

When `sscanf` encounters a percent character in the format string, it attempts to convert the corresponding text in the scan string into a number or string, depending on the conversion character following the percent, and stores the resulting number or string in the corresponding variable in the parameter list. In the example, "%f" converts the text "1.234" into a number which it stores in the local variable `v1`.

A conversion specification consists of:

- A percent character ("%").
- An optional "*", which is a conversion suppression character.
- An optional number, which is a maximum field width.
- A conversion character, which specifies how to interpret text in the scan string.

Don't worry about the suppression character and the maximum width specification for now. They will be explained later.

The `sscanf` operation supports a subset of the conversion characters supported by the C `sscanf` operation. The supported conversion characters, which are case-sensitive, are:

- | | |
|---|--|
| d | Converts text representing a decimal number into an integer numeric value. |
| i | Converts text representing a decimal, octal or hexadecimal number into an integer value. If the text starts with "0x" (zero-x), it is interpreted as hexadecimal. Otherwise, if it starts with "0" (zero), it is interpreted as octal. Otherwise it is interpreted as decimal. |
| o | Converts text representing an octal number into an integer numeric value. |
| u | Converts text representing an unsigned decimal number into an integer numeric value. |
| x | Converts text representing a hexadecimal number into an integer numeric value. |
| c | Converts a single character into an integer value which is the ASCII code representing that character. |
| e | Converts text representing a decimal number into a floating point numeric value. |
| f | Same as e. |
| g | Same as e. |
| s | Stores text up to the next white space into a string. |

[Stores text that matches a list of specific characters into a string. The list consists of the characters inside the brackets ("%[abc]"). If the first character is "^", this means to match any character that is **not** in the list. You can specify a range of characters to match. For example "%[A-Z]" matches all of the upper case letters and "%[A-Za-z]" matches all of the upper and lower case letters.

Here are some simplified examples to illustrate each of these conversions.

Variable v1
String s1

Convert text representing a decimal number to an integer value:

```
sscanf "1234", "%d", v1
```

Convert text representing a decimal, octal, or hexadecimal number:

```
sscanf "1.234", "%i", v1          // Convert from decimal.
sscanf "01234", "%i", v1          // Convert from octal.
sscanf "0x123", "%i", v1          // Convert from hex.
```

Convert text representing an octal number:

```
sscanf "1234", "%o", v1
```

Convert text representing an unsigned decimal number:

```
sscanf "1234", "%u", v1
```

Convert text representing a hexadecimal number:

```
sscanf "1FB9", "%x", v1
```

Convert a single character:

```
sscanf "A", "%c", v1
```

Convert text representing a decimal number to an floating point value:

```
sscanf "1.234", "%e", v1
sscanf "1.234", "%f", v1
sscanf "1.234", "%g", v1
```

Copy a string of text up to the first white space:

```
sscanf "Hello There", "%s", s1
```

Copy a string of text matching the specified characters:

```
sscanf "+4.27", "%[+-]", s1
```

In a C program, you will sometimes see the letters "l" (ell) or "h" between the percent and the conversion character. For example, you may see "%lf" or "%hd". These extra letters are not needed or tolerated by Igor's sscanf operation.

When sscanf matches the format string to the scan string, it reads from the scan string until a character that would be inappropriate for the section of the format string that sscanf is trying to match. In the following example, sscanf stops reading characters to be converted into a number when it hits the first character that is not appropriate for a number.

Variable v1
String s1, s2
sscanf "1234Volts DC", "%d%s %s", v1, s1, s2

sscanf stops matching text for "%d" when it hits "V" and stores the converted number in v1. It stops matching text for the first "%s" when it hits white space and stores the matched text in s1. It then skips the space in the scan string because of the corresponding space in the format string. Finally, it matches the remaining text to the second "%s" and stores the text in s2.

The maximum field width must appear just before the conversion character ("d" in this case).

Variable v1, v2
sscanf "12349876", "%4d%4d", v1, v2

The suppression character ("") is used in a conversion specification to skip values in the scan string. It parses the value, but sscanf does not store the value in any variable. In the following example, we read one number into local variable v1, skip a colon, and read another number into local variable v2, skip a colon, and read another number into local variable v3.

Variable v1, v2, v3
sscanf "12:30:45", "%d%*[:]d%*[:]d", v1, v2, v3

Here "%*[:]" means "read a colon character but don't store it anywhere". The "" character must appear immediately after the percent. Note that there is nothing in the parameter list corresponding to the suppressed strings.

Stack

If the text in the scan string is not consistent with the text in the format string, `sscanf` may not read all of the values that you expected. You can check for this using the `V_flag` variable, which is set to the number of values read. This kind of inconsistency does not cause `sscanf` to return an error to Igor, which would cause procedure execution to abort. It is a situation that you can deal with in your procedure code.

The `sscanf` operation returns the following kinds of errors:

- Out-of-memory.
- The number of parameters implied by *formatStr* does not match the number of parameters in the *var* list.
- *formatStr* calls for a numeric variable but the parameter list expects a string variable.
- *formatStr* calls for a string variable but the parameter list expects a numeric variable.
- *formatStr* includes an unsupported, unknown or incorrectly constructed conversion specification.
- The *var* list references a global variable that does not exist.

Examples

Here is a simple example to give you the general idea:

```
Function SimpleExample()  
  Variable v1, valuesRead  
  sscanf "Value=1.234", "Value=%g", v1  
  valuesRead = V_flag  
  if (valuesRead != 1)  
    Printf "Error: Expected 1 value, got %d values\r", valuesRead  
  else  
    Printf "Value read = %g\r", v1  
  endif  
End
```

For an example that uses `sscanf` to load data from a text file, see the Load File Demo example in "Igor Pro Folder:Examples:Programming".

`str2num`, `strsearch`, and `stringmatch`.

Stack

Stack [*flags*] [*objectName*][, *objectName*]...

The **Stack** operation stacks the named objects in the top page layout.

Parameters

objectName is the name of a graph, table, picture or annotation object in the top page layout.

Flags

/A=(rows,cols)	/I	/O=objTypes	/S
/G=grout	/M	/R	/W=(left,top,right,bottom)

See Also

The **Tile** operation for details on the flags and parameters.

StackWindows

StackWindows [*flags*] [*windowName* [, *windowName*]...]

The **StackWindows** operation stacks the named windows on the desktop.

Flags

/A=(rows,cols)	/G=grout	/O=objTypes	/P	/W=(left,top,right,bottom)
/C	/I	/M	/R	

See Also

See the **TileWindows** operation for details on the flags and parameters.

startMSTimer

startMSTimer

The startMSTimer function creates a new microsecond timer and returns a timer reference number.

Details

You can create up to ten different microsecond timers using startMSTimer. A valid timer reference number is a number between 0 and 9. If startMSTimer returns -1, there are no free timers available. startMSTimer works in conjunction with stopMSTimer.

See Also

The stopMSTimer and ticks functions.

Static

Static constant *objectName* = *value*

Static strconstant *objectName* = *value*

Static Function *funcName*()

Static Picture *pictName*

The Static keyword declaration specifies that a constant, user function, or Proc Picture is local to the procedure file in which it appears. Static objects can only be used by other functions; they cannot be accessed from macros; they cannot be accessed from other procedure files or from the command line.

See Also

Static Functions on page IV-65, Proc Pictures on page IV-44, and Constants on page IV-38.

StatsAngularDistanceTest

StatsAngularDistanceTest [*flags*][*srcWave1*, *srcWave2*, *srcWave3*...]

The StatsAngularDistanceTest operation performs nonparametric tests on the angular distance between sample data and reference directions for two or more samples in individual waves. The angular distance is the shortest distance between two points on a circle (in radians). Specify the sample waves using /WSTR or by listing them following the flags. Set reference directions with /ANG, /ANGW, or the sample mean direction.

Flags

- /ALPH=*val* Sets the significance level (default 0.05).
- /ANG={*d1*, *d2*} Sets reference directions (in radians) for two samples; for more than two samples use /ANGW.
- /ANGM Computes the mean direction of each sample and uses it as the reference direction.
- /ANGW=*dWave* Sets reference directions (in radians) for more than two samples using directions in *dWave*, which must be single or double precision.
- /APRX=*m* Controls the approximation method for computing the P-value in the case of two samples (Mann-Whitney Wilcoxon). See **StatsWilcoxonRankTest** for more details. The default value is 0, which may require long computation times if your sample size is large. Use /APRX=1 if you have a large sample and you expect ties in the data.
- /Q No results printed in the history area.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 - k*=0: Normal with dialog (default).
 - k*=1: Kills with no dialog.
 - k*=2: Disables killing.
- /TAIL=*tail* *tail*=1: Lower tail.
 - tail*=2: Upper tail (default).
 - tail*=4: Two tail.

Use any test combination by adding the values. The P value corresponding to the last tail calculated will be entered in the table.
- /WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The inputs for StatsAngularDistanceTest are two or more waves each corresponding to individual sample. The waves must be single or double precision expressing the angles in radians. There is no restriction on the number of points or dimensionality of the waves but the data should not contain NaNs or INFs. We recommend that you use double precision waves, especially if there are ties in the data. The reference directions should also be in radians. For two samples, StatsAngularDistanceTest computes the angular distances between the input data and the reference directions and then uses the Mann-Whitney-Wilcoxon test (**StatsWilcoxonRankTest**). Results are stored in the W_WilcoxonTest wave and in the corresponding table. For more than two samples, StatsAngularDistanceTest uses the Kruskal-Wallis test, storing results in the wave W_KWTestResults wave in the current data folder.

V_flag will be set to -1 for any error and to zero otherwise.

Examples:Statistics:Circular Statistics:AngularDistanceTest.pxp.

StatsANOVA1Test

StatsANOVA1Test [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsANOVA1Test operation performs a one-way ANOVA test (fixed-effect model). The standard ANOVA test results are stored in the M_ANOVA1 wave in the current data folder.

Flags

/ALPH=*val* Sets the significance level (default 0.05).
/BF Performs the Brown and Forsythe test computing F' and degrees of freedom. The W_ANOVA1BnF wave in the current data folder contains the output.
/Q No results printed in the history area.
/T=*k* Displays results in a table; additional tables are created with /BF and /W. *k* specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.
/W Performs the Welch test F' and computes degrees of freedom. The W_ANOVA1Welch wave in the current data folder contains the output.
/WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Inputs to StatsANOVA1Test are two or more 1D numerical waves containing (one wave for each group of samples). Use NaN for missing entries or use waves with different numbers of points. The standard ANOVA results are in the M_ANOVA1 wave with corresponding row and column labels. Use /T to display the results in a table. In each case you will get the two degrees of freedom values, the F value, the critical value Fc for the choice of alpha and the degrees of freedom, and the P-value for the result. V_flag will be set to -1 for any error and to zero otherwise.

In some cases the ANOVA test may not be appropriate. For example, if groups do not exhibit sufficient homogeneity of variances. Although this may not be fatal for the ANOVA test, you may get more insight by performing the variances test in **StatsVariancesTest**.

If there are only two groups this test should be equivalent to **StatsTTest**.

You can evaluate the power of an ANOVA test for a given set of degrees of freedom and noncentrality parameter using:

```
power=1-StatsNCFCDF(StatsInvFCDF((1-alpha),n1,n2),n1,n2,delta)
```

Here n1 is the Groups' degrees of freedom, n2 is the Error degrees of freedom, and delta is the noncentrality parameter. For more information see ANOVA Power Calculations Panel and the associated example experiment.

Zar, J.H., *Biostatistical Analysis*, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsVariancesTest**, **StatsTTest**, **StatsNCFCDF**, and **StatsInvFCDF**.

StatsANOVA2NRTest

StatsANOVA2NRTest [*flags*] *srcWave*

The StatsANOVA2NRTest operation performs a two-factor analysis of variance (ANOVA) on the data that has no replication where there is only a single datum for every factor level. *srcWave* is a 2D wave of any numeric type. Output is to the M_ANOVA2NRResults wave in the current data folder or optionally to a table.

Flags

/ALPH=*val* Sets the significance level (default 0.05).
 /FOMD Estimates one missing value. You will also have to use a single or double precision wave for *srcWave* and designate the single missing value as NaN. The estimated value is printed to the history as well as the bias used to correct the sum of the squares of factor A.
 /INT=*val* Sets the degree of interactivity.
val=0: No interaction between the factors (default).
val=1: Significant interaction effect between factors.
 Combination with /MODL determines which factors to test:

<i>val</i>	Model 1	Model2	Model3
1		A&B	A
0	A&B	A&B	A&B

/MODL=*m* Sets the model number.
m=1: Factor A and factor B are fixed.
m=2: Both factors are random.
m=3: Factor A is fixed and factor B is random (default).
 /Q No results printed in the history area.
 /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
 The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
 /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Input to StatsANOVA2NRTest is the 2D *srcWave* in which the factor A levels are columns and the factor B levels are rows. NaN and INF entries are not supported although you may use a single NaN value in combination with the /FOMD. If *srcWave* contains dimension labels they will be used to designate the two factors in the output.

The contents of the M_ANOVA2NRResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical F value (F_c)

for the specified alpha, and the last contains the conclusion with 0 to reject H_0 or 1 to accept it. In each case H_0 corresponds to the assumption that there is no difference in the means of the respective populations.

V_flag will be set to -1 for any error and to zero otherwise.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test** and **StatsANOVA2Test**.

StatsANOVA2RMTest

StatsANOVA2RMTest [*flags*] *srcWave*

The StatsANOVA2RMTest operation performs analysis of variance (ANOVA) on *srcWave* where replicates consist of multiple measurements on the same subject (repeated measures). *srcWave* is a 2D wave of any numeric type. Output is to the M_ANOVA2RMResults wave in the current data folder or optionally to a table.

Flags

/ALPH= <i>val</i>	Sets the significance level (default 0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Input to StatsANOVA2RMTest is the 2D *srcWave* in which the factor A (Groups) are columns and the different subjects are rows. It does not support NaNs or INFs.

The contents of the M_ANOVA2RMResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the single F value for this test, the fifth contains the critical F value for the specified alpha and degrees of freedom, and the last column contains the conclusion with 0 to reject H_0 or 1 to accept it. In each case H_0 corresponds to the mean level, which is the same for all subjects.

V_flag will be set to -1 for any error and to zero otherwise.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA2NRTest** and **StatsANOVA2Test**.

StatsANOVA2Test

StatsANOVA2Test [*flags*] *srcWave*

The StatsANOVA2Test operation performs a two-factor analysis of variance (ANOVA) on *srcWave*. Output is to the M_ANOVA2Results wave in the current data folder or optionally to a table.

Flags

/ALPH= <i>val</i>	Sets the significance level (default 0.05).
/FAKE= <i>num</i>	Specifies the number of points in <i>srcWave</i> obtained by "estimation". <i>num</i> is subtracted from the total and error degrees of freedom.
/MODL= <i>m</i>	Sets the model number. <i>m</i> =1: Factor A and factor B are fixed (default). <i>m</i> =2: Both factors are random. <i>m</i> =3: Factor A is fixed and factor B is random.
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default).

$k=1$: Kills with no dialog.

$k=2$: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Input to StatsANOVA2Test is the single or double precision 3D *srcWave* in which the factor A levels are columns, the factor B levels are rows, and the replicates are layers. If *srcWave* contains dimension labels they will be used to designate the factors in the output.

Ideally, the number of replicates must be equal for each factor and each level. StatsANOVA2Test supports both equal replication and proportional replication. Proportional replication allows for different number of data in each cell with missing data represented as NaN and the number of points in each cell is given by

$N_{ij} = (\text{sum of data in row } i) * (\text{sum of data in column } j) / \text{number of samples}.$

If you have no replicates (a single datum per cell) use **StatsANOVA2NRTest** instead. If the number of replicates in your data does not satisfy these conditions you may be able to “estimate” additional replicates using various methods. In that case use the /FAKE flag so that the operation can account for the estimated data by reducing the total and error degrees of freedom. /FAKE only accounts for the number of estimates being used. You must provide an appropriate number of estimated values.

The contents of the M_ANOVA2Results output wave columns are: the first contains the sum of the squares (SS) values, the second the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical Fc value for the specified alpha and degrees of freedom, and the last contains the conclusion with 0 to reject H_0 or 1 to accept it. In each case H_0 corresponds to the mean level, which is the same for all populations.

V_flag will be set to -1 for any error and to zero otherwise.

StatsBetaCDF

StatsBetaCDF(x, p, q [, a, b])

The StatsBetaCDF function returns the beta cumulative distribution function

$$F(x;p,q,a,b) = \frac{1}{B(p,q)} \int_0^{x-a} t^{p-1} (1-t)^{q-1} dt, \quad \begin{matrix} p,q > 0 \\ a \leq x \leq b \end{matrix}$$

where $B(p,q)$ is the beta function $B(p,q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt.$

The defaults ($a=0$ and $b=1$) correspond to the standard beta distribution where a is the location parameter, ($b-a$) is the scale parameter, and p and q are shape parameters.

Chapter III-12, **Statistics** for a function and operation overview; **StatsBetaPDF** and **StatsInvBetaCDF**.

StatsBetaPDF

StatsBetaPDF(x, p, q [, a, b])

The StatsBetaPDF function returns the beta probability distribution function

$$f(x;p,q,a,b) = \frac{(x-a)^{p-1} (b-x)^{q-1}}{B(p,q)(b-a)^{p+q-1}}, \quad \begin{matrix} a \leq x \leq b \\ p,q > 0 \end{matrix}$$

where $B(p,q)$ is the beta function $B(p,q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt.$

StatsBinomialCDF

The defaults ($a=0$ and $b=1$) correspond to the standard beta distribution where a is the location parameter, ($b-a$) is the scale parameter, and p and q are shape parameters. When $p < 1$, $f(x=a)$ returns Inf.

StatsCauchyCDF

StatsCauchyCDF(x, α, σ)

The StatsCauchyCDF function returns the Cauchy-Lorentz cumulative distribution function

$$F(x, \mu, \sigma) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1} \left(\frac{x - \mu}{\sigma} \right)$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsCauchyPDF**.

StatsCauchyPDF

StatsCauchyPDF(x, α, σ)

The StatsCauchyPDF function returns the Cauchy-Lorentz probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{\sigma\pi} \frac{1}{1 + \left(\frac{x - \mu}{\sigma} \right)^2}$$

where α is the location parameter and σ is the scale parameter. Use $\alpha=0$ and $\sigma=1$ for the standard form of the Cauchy-Lorentz distribution.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsInvCauchyCDF**.

StatsChiCDF

StatsChiCDF(x, n)

The StatsChiCDF function returns the chi-squared cumulative distribution function for the specified value and degrees of freedom n .

$$F(x, n) = \frac{\gamma\left(\frac{n}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{n}{2}\right)}$$

where is $\gamma(a, b)$ the incomplete gamma function. The distribution can also be expressed as

$$F(x, n) = 1 - \text{gammapq}\left(\frac{n}{2}, \frac{x}{2}\right)$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiPDF**, **StatsInvChiCDF**, and **gammapq**.

StatsChiPDF

StatsChiPDF(x, n)

The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as

$$f(x, n) = \frac{\exp\left(-\frac{x}{2}\right) x^{\frac{n}{2}-1}}{2^{\frac{n}{2}} \Gamma\left(\frac{n}{2}\right)}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiCDF** and **StatsChiPDF**.

StatsChiTest

StatsChiTest [flags] srcWave1, srcWave2

The StatsANOVA2Test operation computes a χ^2 statistic for comparing two distributions or a χ^2 statistic for comparing a sample distribution with its expected values. In both cases the comparison is made on a bin-by-bin basis. Output is to the W_StatsChiTest wave in the current data folder or optionally to a table.

Flags

/NCON= $nCon$	Specifies the number of constraints (0 by default), which reduces the number degrees of freedom and the critical value by $nCon$.
/S	Sets the calculation mode to a single distribution where <i>srcWave1</i> represents an array of binned measurements and <i>srcWave2</i> represents the corresponding expected values.
/T= k	Displays results in a table. k specifies the table behavior when it is closed. $k=0$: Normal with dialog (default). $k=1$: Kills with no dialog. $k=2$: Disables killing.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The source waves, *srcWave1* and *srcWave2*, must have the same number of points and can be any real numeric data type. Any nonpositive values (including NaN) in either wave removes the entry in both waves from consideration and reduces the degrees of freedom by one. The number degrees of freedom is initially the number of points in *srcWave1*-1- $nCon$. By default it is assumed that *srcWave1* and *srcWave2* represent two distributions of binned data.

When you specify /S, *srcWave1* must consist of binned values of measured data and *srcWave2* must contain the corresponding expected values. The calculation is:

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_i - V_i)^2}{V_i}$$

Here Y_i is the sample point from *srcWave1*, V_i is the expected value of Y_i based on an assumed distribution (*srcWave2*), and n is the number of points in the each wave. If you do not use /S, it calculates:

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_{1i} - Y_{2i})^2}{Y_{1i} + Y_{2i}}$$

where Y_{1i} and Y_{2i} are taken from *srcWave1* and *srcWave2* respectively.

V_flag will be set to -1 for any error and to zero otherwise.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsContingencyTable**.

StatsCircularCorrelationTest

StatsCircularCorrelationTest [*flags*] *waveA*, *waveB*

The StatsCircularTwoSampleTest operation performs parametric and nonparametric tests for angular-angular and angular-linear correlations. Input waves, *waveA* and *waveB*, contain angles (in radians) as either single or double precision values and must have the same number of points. If you make more than one test, they are in the order /PAA, /PAL, and /NAA. Output is to the W_StatsCircularCorrelationTest wave in the current data folder or optionally to a table.

Flags

/ALPH= <i>val</i>	Sets the significance level (default 0.05).
/NAA	Performs a nonparametric angular-angular correlation test.
/PAA	Performs a parametric angular-angular correlation test.
/PAL	Performs a parametric angular-linear correlation test. In this case the angle wave is <i>waveA</i> and the linear data corresponds to <i>waveB</i> .
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed.
	<i>k</i> =0: Normal with dialog (default).
	<i>k</i> =1: Kills with no dialog.
	<i>k</i> =2: Disables killing.
/Z	Ignores errors.

Details

The nonparametric test (/NAA) follows Fisher and Lee's modification of Mardia's statistic, which is an analogue of Spearman's rank correlation. The test ranks the angles of each sample and computes the quantities r' and r'' as follows:

$$r' = \frac{\left\{ \sum_{i=0}^{n-1} \cos \left[\frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[\frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2}{n^2}$$

$$r'' = \frac{\left\{ \sum_{i=0}^{n-1} \cos \left[\frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[\frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2}{n^2}$$

Here n is the number of data pairs and r_{ai} and r_{bi} are the ranks of the i th member in the first and second samples respectively.

The test statistic is $(n-1)(r'-r'')$, which is compared with the critical value (for one and two tails). The CDF of the statistic is a highly irregular function. The critical value is computed by a different methods according to n . For $3 \leq n \leq 8$, a built-in table of CDF transitions gives a "conservative" estimate of the critical value. For

$9 \leq n \leq 30$, the CDF is approximated by a 7th order polynomial in the region $x > 0$. For $n \geq 30$, the CDF is from the asymptotic expression. For $3 \leq n \leq 30$, CDF values are obtained by Monte-Carlo simulations using $1e6$ random samples for each n .

The parametric test for angular-angular correlation (/PAA) involves computation of a correlation coefficient r_{aa} and then evaluating the mean $\overline{r_{aa}}$ and variance $s_{r_{aa}}^2$ of equivalent correlation coefficients computed from the same data but by deleting a different pair of angles each time. The mean and variance are then used to compute confidence limits L1 and L2:

$$L1 = n\overline{r_{aa}} - (n-1)\overline{r_{aa}} - Z_{\alpha(2)}\sqrt{\frac{s_{r_{aa}}^2}{n}} \quad L2 = n\overline{r_{aa}} - (n-1)\overline{r_{aa}} + Z_{\alpha(2)}\sqrt{\frac{s_{r_{aa}}^2}{n}}$$

where $Z_{\alpha(2)}$ is the normal distribution two-tail critical value at the a level of significance. H_0 (corresponding to no correlation) is rejected if zero is not contained in the interval [L1,L2].

The parametric test for angular-linear correlation (/PAL) involves computation of the correlation coefficient r_{al} which is then compared with a critical value from χ^2 for alpha significance and two degrees of freedom.

$$r_{al} = \sqrt{\frac{r_{ac}^2 + r_{cs}^2 - 2r_{ac}r_{cs}r_{cc}}{1 - r_{cc}^2}}$$

where:

$$r_{ac} = \frac{\sum_{i=0}^{n-1} X_i \cos(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i \right)^2 \right) \left(\sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \cos(a_i) \right)^2 \right)}}$$

$$r_{cs} = \frac{\sum_{i=0}^{n-1} X_i \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \sin(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i \right)^2 \right) \left(\sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \sin(a_i) \right)^2 \right)}}$$

$$r_{cc} = \frac{\sum_{i=0}^{n-1} \cos(a_i) \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} \sin(a_i) \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left(\sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \sin(a_i) \right)^2 \right) \left(\sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left(\sum_{i=0}^{n-1} \cos(a_i) \right)^2 \right)}}$$

StatsCircularMeans

StatsCircularMeans [flags] srcWave

The StatsCircularMeans operation calculates the mean of a number of circular means, returning the mean angle (grand mean), the length of the mean vector, and optionally confidence interval around the mean angle. Output is to the history area and to the W_CircularMeans wave in the current data folder.

Flags

/ALPH=val Sets the significance level (default 0.05).
 /CI Calculates the confidence interval (labeled CI_t1 and CI_t2) around the mean angle.
 /NSOA Performs nonparametric second order analysis according to Moore's version of Rayleigh's test where H_0 corresponds to uniform distribution around the circle. Moore's test ranks entries by the lengths of the mean radii (second column of the input) from smallest (rank 1) to largest (rank n) and then computes the statistic:

$$R^* = \sqrt{\frac{\left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \cos(a_i)\right)^2 + \left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \sin(a_i)\right)^2}{n}}$$

where a_i are the mean angle entries (from column 1) corresponding to vector length rank $(i+1)$. The critical value is obtained from Moore's distribution **StatsInvMooreCDF**.

/PSOA

Perform parametric second order analysis where H_0 corresponds to no mean population direction. It assumes that the second order quantities are from a bivariate normal distribution. If this is not the case, use /NSOA above. The test statistic is:

$$F = \frac{k(k-2)}{2} \left[\frac{\bar{X}^2 S_{Y^2} - 2\bar{X}\bar{Y}S_{XY} + \bar{Y}^2 S_{X^2}}{S_{X^2}S_{Y^2} - S_{XY}^2} \right]$$

where

$$\begin{aligned} \bar{X} &= \frac{1}{n} \sum_{i=0}^{n-1} X_i = \frac{1}{n} \sum_{i=0}^{n-1} r_i \cos(a_i) & \bar{Y} &= \frac{1}{n} \sum_{i=0}^{n-1} Y_i = \frac{1}{n} \sum_{i=0}^{n-1} r_i \sin(a_i) & S_{X^2} &= \sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} X_i \right)^2 \\ S_{Y^2} &= \sum_{i=0}^{n-1} Y_i^2 - \frac{1}{n} \left(\sum_{i=0}^{n-1} Y_i \right)^2 & S_{XY} &= \sum_{i=0}^{n-1} X_i Y_i - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} Y_i \end{aligned}$$

Here n is the number of means in *srcWave* and the critical value is computed from the F distribution, equivalent to executing: `Print StatsInvFCDF(1-alpha, 2, n-2)`.

/Q

No results printed in the history area.

/T=k

Displays results in a table. k specifies the table behavior when it is closed.

$k=0$: Normal with dialog (default).

$k=1$: Kills with no dialog.

$k=2$: Disables killing.

/Z

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The *srcWave* input to StatsCircularMeans must be a single or double precision two column wave containing in each row a mean angle (radians) and the length of a mean radius (the first column contains mean angles and the second column contains mean vector lengths). *srcWave* must not contain any NaNs or INFs. The confidence interval calculation follows the procedure outlined by Batschelet.

V_flag will be set to -1 for any error and to zero otherwise.

Chapter III-12, **Statistics** for a function and operation overview; **StatsCircularMoments**, **StatsInvMooreCDF**, and **StatsInvFCDF**.

StatsCircularMoments

StatsCircularMoments [flags] srcWave

The StatsCircularMoments operation computes circular statistical moments and optionally performs angular uniformity tests for the data in *srcWave*. The extent of the calculation is determined by the requested moment. The default results are stored in the W_CircularStats wave in the current data folder and are optionally displayed in a table. Additional results are listed under the corresponding flags.

Flags

/ALPH=alpha

Sets an *alpha* value for computing confidence intervals (default is 0.05).

/AXD=p

Designates the input as p-axial data. For example, if the input represents undirected lines then $p=2$ and the operation multiplies the angles by a factor p (after shifting /ORGN and accounting for /CYCL). It does not back-transform the mean or median axis.

/CYCL= <i>cycle</i>	Specifies the length of the data cycle. You do not need to do so if you are using one of the built-in modes, but this is still a useful option, as for setting the length of a particular month when using /MODE=5.																				
/GRPD={ <i>start, delta</i> }	Computes circular statistics for grouped data. In this case <i>srcWave</i> contains frequencies or the number of events that belong to a particular angle group. There are as many groups as there are elements in <i>srcWave</i> . The first group is centered at <i>start</i> radians and each consecutive group is centered <i>delta</i> radians away. You must set both the <i>start</i> and <i>delta</i> to sensible values. <i>srcWave</i> may contain NaNs but it is an error if all values are NaN. The only other flags that work in combination with this flag are /Q, /T, and /Z.																				
/KUPR	<p>Tests the uniformity of the distribution for ungrouped data using Kuiper statistic. The data are converted into a set $\{x_i\}$ by normalizing the input angles to the range $[0,1]$, ranking the results then using the two quantities D_+ and D_- to compute the Kuiper statistic</p> $V = (D_+ + D_-)(\sqrt{n} + 0.155 + 0.24 \sqrt{n})$ <p>where</p> $D_+ = \text{Max of: } \frac{1}{n} - x_0, \frac{2}{n} - x_1, \dots, 1 - x_{n-1} \quad D_- = \text{Max of: } x_0, x_1 - \frac{1}{n}, \dots, x_{n-1} - \frac{n-1}{n}$ <p>and n is the number of valid points in <i>srcWave</i>. You can find the results in the wave W_CircularStats under row label "Kuiper V" and "Kuiper CDF(V)". See Fisher and Press <i>et al.</i> for more information.</p>																				
/LOS	Computes Linear Order Statistics by sorting the angle values from small to large, dividing each angle by 2π and shifting the origin so that the output range is $[0,1]$. The results are stored in the wave W_LinearOrderStats in the current data folder. The X scaling of the wave is set so that the offset and the delta are $1/(n+1)$ where n is the number of non-NaN points in the input.																				
/M= <i>moment</i>	Computes specified moments. By default, it computes the second order moments as well as skewness, kurtosis, median, and mean deviation. Use /M=1 for the first moment. For higher moments, both the specified moment and all the default quantities are computed.																				
/MODE= <i>mode</i>	Handles special types of data.																				
<table> <tr> <th><i>mode</i></th><th>Data in <i>srcWave</i></th></tr> <tr> <td>0</td><td>Angles in radians $[0, 2\pi]$</td></tr> <tr> <td>1</td><td>Angles in radians $[-\pi, \pi]$</td></tr> <tr> <td>2</td><td>Angles in degrees $[0, 360]$</td></tr> <tr> <td>3</td><td>Angles in degrees $[-180, 180]$</td></tr> <tr> <td>4</td><td>Igor date format for one year cycles.</td></tr> <tr> <td>5</td><td>Igor date format for one month cycles.</td></tr> <tr> <td>6</td><td>Igor date format for one week cycles.</td></tr> <tr> <td>7</td><td>Igor date format for one day cycles.</td></tr> <tr> <td>8</td><td>Igor date format for one hour cycles.</td></tr> </table>		<i>mode</i>	Data in <i>srcWave</i>	0	Angles in radians $[0, 2\pi]$	1	Angles in radians $[-\pi, \pi]$	2	Angles in degrees $[0, 360]$	3	Angles in degrees $[-180, 180]$	4	Igor date format for one year cycles.	5	Igor date format for one month cycles.	6	Igor date format for one week cycles.	7	Igor date format for one day cycles.	8	Igor date format for one hour cycles.
<i>mode</i>	Data in <i>srcWave</i>																				
0	Angles in radians $[0, 2\pi]$																				
1	Angles in radians $[-\pi, \pi]$																				
2	Angles in degrees $[0, 360]$																				
3	Angles in degrees $[-180, 180]$																				
4	Igor date format for one year cycles.																				
5	Igor date format for one month cycles.																				
6	Igor date format for one week cycles.																				
7	Igor date format for one day cycles.																				
8	Igor date format for one hour cycles.																				
/ORGN= <i>origin</i>	Specifies the origin of the data (the value corresponding to an angle of zero degrees). For example, if you are using Igor date format and you want the origin to be the first second in year YYYY, use /ORGN=(date2secs(YYYY, 1, 1)).																				
/Q	No results printed in the history area.																				
/RAYL[= <i>meanDirection</i>]	<p>Performs the Rayleigh test for uniformity. If the "alternative" mean direction is specified (in radians), the test computes</p> $r0Bar = rBar \cos(tBar - meanDirection)$ <p>and then computes the significance probability of $r0Bar$. The null hypothesis H_0 corresponds to uniformity. It is rejected when $r0Bar$ is too large. If the mean direction is not specified then $r0Bar$ is $rBar$ which is always calculated as part of the first moments so</p>																				

	the operation only computes the relevant significance probability (P-Value). The critical values for both cases are computed according to Durand and Greenwood.
/SAW	Saves the translated angle data in the wave W_AngleWave in the current data folder.
/T=k	Displays results in a table. k specifies the table behavior when it is closed. $k=0$: Normal with dialog (default). $k=1$: Kills with no dialog. $k=2$: Disables killing. The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists, but does not display the output wave from the current data folder, the table is renamed and a new table is created.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsCircularMoments is equivalent to **WaveStats** but it applies to circular data, which are distributed on the perimeter of a circle representing some period or cycle. If your data are not described by one of the built-in modes, you can specify the value of the origin (/ORGN), which is mapped to zero degrees and the size of a cycle or period.

When you use Igor date formats with the built-in modes for dates, the default origin is set to zero. The default cycle in the case of Mode 4 is 366. This is done in order to handle both leap and nonleap years. Similarly, Mode 5 uses a cycle of 31 days. Note that the internal conversion from Igor date to (year, month, day) is independent of the cycle specification and is therefore not affected by this choice. You should use the /CYCL flag if you use one of these modes with a fixed size of year or month.

The parameters listed below are computed and displayed (see row labels) in the table. Here N is the number of valid (non-NaN) angles $\{\theta_i\}$

$$C = \sum_{i=1}^n \cos \theta_i \quad S = \sum_{i=1}^n \sin \theta_i \quad R = \sqrt{C^2 + S^2}$$

$$cBar = \bar{C} = C/N \quad sBar = \bar{S} = S/N \quad rBar = \bar{R} = R/N \quad tBar = \bar{\theta} = \begin{cases} \text{atan}(S/C) & S > 0, C > 0 \\ \text{atan}(S/C) + \pi & C > 0 \\ \text{atan}(S/C) + 2\pi & S < 0, C > 0 \end{cases}$$

$$V = 1 - \bar{R} \quad v = \sqrt{-2 \log(1 - V)}$$

$$\text{median is the value which minimizes } d(\theta) = \pi - \frac{1}{n} \sum_{i=1}^n |\pi - |\theta_i - \bar{\theta}||$$

mean deviation = The minimum of the last equation when $q \rightarrow \text{median}$.

Higher order moments are denoted with the moment number such that t3Bar is the uncentered third moment of the angle while primed quantities are relative to mean direction tBar. Using this notation

$$\hat{\rho}_2 = \frac{1}{n} \sum_{i=1}^n \cos 2(\theta_i - \bar{\theta})$$

$$\text{circular dispersion} = \frac{1 - \hat{\rho}_2}{2\bar{R}^2} \quad \text{skewness} = \frac{\hat{\rho}_2 \sin(\hat{\alpha}_2' - 2\bar{\theta})}{(1 - \bar{R})^3} \quad \text{kurtosis} = \frac{\hat{\rho}_2 \cos(\hat{\alpha}_2' - 2\bar{\theta}) - \bar{R}^4}{(1 - \bar{R})^2}$$

$$\text{where } \hat{\alpha}_p' = \begin{cases} \text{atan}(S_p/C_p) & S_p > 0, C_p > 0 \\ \text{atan}(S_p/C_p) + \pi & C_p < 0 \\ \text{atan}(S_p/C_p) + 2\pi & S_p < 0, C_p > 0 \end{cases} \quad \text{and } C_p = \frac{1}{n} \sum_{i=1}^n \cos p\theta_i \quad S_p = \frac{1}{n} \sum_{i=1}^n \sin p\theta_i$$

StatsCircularTwoSampleTest

StatsCircularTwoSampleTest [*flags*] *waveA*, *waveB*

The StatsCircularTwoSampleTest operation performs second order analysis of angles. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data (mean angles) expressed in radians and an optional second column that contains associated vector lengths. The waves must be either single or double precision. Results are stored in the W_StatsCircularTwoSamples wave in the current data folder and optionally displayed in a table. Some of the tests may have additional outputs.

Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/NPR	Performs nonparametric paired-sample test (Moore). The input waves must contain paired angular data so both must have single column and the same number of points.
/NSOA	Perform nonparametric second order two-sample test. Input waves must each contain two columns.
/PPR	Performs parametric paired-sample test. Input waves must contain paired data and must have the same number of points.
/PSOA	Performs parametric second order analysis of two samples. The input waves must each contain two columns.
/Q	No information printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores any errors.

Details

The nonparametric paired-sample test (/NPR) is Moore's test for paired angles applied in second order analysis. The input can consist of one or two column waves. When both waves contain a single column the operation proceeds as if all the vector length were identically 1. The Moore statistic ($H_0 \rightarrow$ pair equality) is computed and compared to the critical value from the Moore distribution (see **StatsInvMooreCDF**).

The nonparametric second-order two-sample test (/NSOA) consists of pre-processing where the grand mean is subtracted from the two inputs followed by application of Watson's U^2 test (**StatsWatsonUSquaredTest**) with H_0 implying that the two samples came from the same population. The results of this test are stored in the wave W_WatsonUtest.

The parametric paired-sample test (/PPR) is due to Hotelling. In this test the input should consist of both angular and vector length data. The test statistic is compared with a critical value from the F distribution (**StatsInvFCDF**).

The parametric second order two-sample test (/PSOA) is an extension of Hotelling one-sample test to second order analysis where an F-like statistic is computed corresponding to H_0 of equal mean angles.

StatsCMSSDCDF**StatsCMSSDCDF(C, n)**

The StatsCMSSDCDF function returns the cumulative distribution function of the C distribution (mean square successive difference), which is

$$f(C, n) = \frac{\Gamma(2m+2)}{a2^{2m+1}[\Gamma(m+1)]^2} \left(1 - \frac{C^2}{a^2}\right)^m \quad \text{where } a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)} \quad m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}$$

The distribution ($C > 0$) can then be expressed as

$$F(C, n) = \frac{\Gamma(2m+2)}{a2^{2m+1}[\Gamma(m+1)]^2} C {}_2F_1\left(\frac{1}{2}, -m, \frac{3}{2}, \frac{C^2}{a^2}\right) \quad \text{where } {}_2F_1 \text{ is the hypergeometric function } \mathbf{hyperG2F1}.$$

Chapter III-12, **Statistics** for a function and operation overview; **StatsCMSSDCDF** and **StatsSRTest**.

StatsCochranTest**StatsCochranTest [flags] [wave1, wave2,... wave100]**

The StatsCochranTest operation performs Cochran's (Q) test on a randomized block or repeated measures dichotomous data. Output is to the M_CochranTestResults wave in the current data folder or optionally to a table.

Flags

- /ALPH = val Sets the significance level (default val=0.05).
- /Q No results printed in the history area.
- /T=k Displays results in a table. k specifies the table behavior when it is closed.
k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
- The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.
- /WSTR=waveListString Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
- /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The StatsCochranTest computes Cochran's statistic and compares it to a critical value from a Chi-squared distribution, which depends only of the significance level and the number of groups (columns). The Chi-square distribution is appropriate when there are at least 4 columns and at least 24 total data.

Dichotomous data are presumed to consist of two values 0 and 1, thus StatsCochranTest distinguishes only between zero and any nonzero value, which is considered to be 1; it does not allow NaNs or INFs. Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. In the standard terminology, data rows represent blocks and data columns represent groups. H_0 corresponds to the assumption that all groups have the same proportion of 1's.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Cochran statistic, the critical value, and the conclusion (1 to accept H_0 and 0 to reject it).

V_flag will be set to -1 for any error and to zero otherwise.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFriedmanTest**.

StatsContingencyTable

StatsContingencyTable [*flags*] srcWave

The StatsContingencyTable operation performs contingency table analysis on 2D and 3D tables. Output is to the W_ContingencyTableResults wave in the current data folder or optionally to a table or the history area.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).
 /COR=*mode* Sets the correction type for 2x2 tables. By default there is no correction. Use *mode*=1 for Yates and *mode*=2 for Haber correction.
 /FEXT={*row*, *col*} Computes Fisher's Exact P-value with 2x2 contingency tables. *row* and *col* are zero-based indices of the table entry where it computes the probability of getting the results in the table or more extreme values. Without the /Q flag, it prints the probabilities of each individual table in the history.
 Given the contingency table:

	Succeeded	Failed
Group1	11	8
Group2	4	9

Example 1: When you use /FEXT={0, 0} the P-value represents the sum of the probabilities of the first group having in the Succeeded column 11 or more extreme values, i.e., 12, 13, 14, and 15. In each case the remaining table elements are adjusted so that row and column sums remain constant.

Example 2: When you needed to evaluate the sum of the probabilities of Group2 having 4 counts or less in the Succeeded column, then the appropriate flag is /FEXT={1, 1}, which effectively computes the equivalent of having 9, 10, 11, 12, and 13 Failed counts. In each case it computes the upper, the lower, and the two-tail probabilities.

/HTRG Tests for heterogeneity between tables stored as layers of 3D wave.
 /LLIK Computes log likelihood statistic.
 /Q No results printed in the history area.
 /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsContingencyTable supports 2D waves representing single contingency tables or 3D waves representing multiple 2D tables (where each table is a layer) or a single 3D table. Each entry in the wave must contain a frequency value and must be a positive number; it does not support 0's, NaNs, or INFs. In the special case of 2x2 tables, use the /COR flag to compute the statistic using either the Yates or Haber corrections. Except for the heterogeneity option you can also compute the log likelihood statistic. In all the tests, H_0 corresponds to independence between the tested variables.

For 3D tables StatsContingencyTable provides Chi-squared, degrees of freedom, the critical value, and optionally the log likelihood G statistic (/LLIK flag) for each of the following cases:

1. Mutual independence by testing if all three variables are independent of each other.

2. Partial dependence (rows) by testing if rows independent of columns and layers.
3. Partial dependence (columns) by testing if columns independent of rows and layers.
4. Partial dependence (layers) by testing if layers independent of rows and columns.

In each case you should compare the statistic with the critical value and reject H_0 if the statistic exceeds or equals the critical value.

You should examine the table entries to determine if the Chi-square statistic is appropriate (if the frequency is smaller than 6 for $\alpha=0.05$ you should consider computing the Fisher exact test).

V_flag will be set to -1 for any error and to zero otherwise.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvChiCDF**.

StatsCorrelation

StatsCorrelation(waveA [, waveB])

The StatsCorrelation function computes Pearson's correlation coefficient between two real valued arrays of data of the same length. Pearson r is give by:

$$r = \frac{\sum_{i=0}^{n-1} (waveA[i] - A)(waveB[i] - B)}{\sqrt{\sum_{i=0}^{n-1} (waveA[i] - A)^2 \sum_{i=0}^{n-1} (waveB[i] - B)^2}}$$

Here A is the average of the elements in $waveA$, B is the average of the elements of $waveB$ and the sum is over all wave elements.

Details

If you use both $waveA$ and $waveB$ then the two waves must have the same number of points but they could be of different number type. If you use only the $waveA$ parameter then $waveA$ must be a 2D wave. In this case StatsCorrelation will return 0 and create a 2D wave M_Pearson where the (i,j) element is Pearson's r corresponding to columns i and j .

Fisher's z transformation converts Person's r above to a normally distributed variable z :

$$z = \frac{1}{2} \ln\left(\frac{1+r}{1-r}\right) \text{ with a standard error } \sigma_z = \frac{1}{\sqrt{n-3}}.$$

You can convert between the two representations using the following functions:

```
Function pearsonToFisher(inr)
  Variable inr
  return 0.5*(ln(1+inr)-ln(1-inr))
End
Function fisherToPearson(inz)
  Variable inz
  return tanh(inz)
End
```

Correlate, **StatsLinearCorrelationTest**, and **StatsCircularCorrelationTest**.

StatsDExpCDF

StatsDExpCDF(x, m, s)

The StatsDExpCDF function returns the double-exponential cumulative distribution function

$$F(x, \mu, \sigma) = \begin{cases} \exp\left(-\frac{x-\mu}{\sigma}\right) & \text{when } x < \mu \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-\mu|}{\sigma}\right) & \text{when } x \geq \mu \end{cases}$$

for $\sigma > 0$. It returns NaN when $\sigma = 0$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpPDF** and **StatsInvDExpCDF**.

StatsDExpPDF**StatsDExpPdf(x, m, s)**

The StatsDExpPdf function returns the double-exponential probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{2\sigma} \exp\left[-\left|\frac{x - \mu}{\sigma}\right|\right]$$

where μ is the location parameter and $\sigma > 0$ is the scale parameter. Use $\mu=0$ and $\sigma=1$ for the standard form of the double exponential distribution. It returns NaN when $\sigma=0$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpCDF** and **StatsInvDExpCDF**.

StatsDIPTest**StatsDIPTest [/Z] srcWave**

The StatsDIPTest operation performs Hartigan test for unimodality.

Flags

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The input to the operation *srcWave* is any real numeric wave. Outputs are: V_Value contains the dip statistic; V_min is the lower end of the modal interval; and V_max is the higher end of the modal interval. Percentage points or critical values for the dip statistic can be obtained from simulations using an identical sample size as in this example:

```
Function getCriticalValue(sampleSize,alpha)
Variable sampleSize,alpha
    Make/O/N=(sampleSize) dataWave
    Make/O/N=100000 dipResults
    Variable i
    for(i=0;i<100000;i+=1)
        dataWave=enoise(100)
        StatsDipTest dataWave
        dipResults[i]=V_Value
    endfor
    Histogram/P/B=4 dipResults           // Compute the PDF.
    Wave W_Histogram
    Integrate/METH=1 W_Histogram/D=W_INT // Compute the CDF.
    Findlevel/Q W_int,(1-alpha)          // Find the critical value.
    return V_LevelX
End
```

Chapter III-12, **Statistics** for a function and operation overview.

StatsDunnettTest**StatsDunnettTest [flags] [wave1, wave2,... wave100]**

The StatsDunnettTest operation performs the Dunnett test by comparing multiple groups to a control group. Output is to the M_DunnettTestResults wave in the current data folder or optionally to a table. StatsDunnettTest usually follows StatsANOVA1Test.

Flags

/ALPH = val Sets the significance level (default val=0.05).
 /CIDX=cIndex Specifies the (zero based) index of the input wave corresponding to the control group.
 The default is zero (the first wave corresponds to the control group).

/Q	No results printed in the history area.
/SWN	Creates a text wave, T_DunnettDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
/T=k	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/TAIL=tc	Specifies H_0 . <i>tc</i> =1: Default; one tailed test ($\alpha_c \leq \alpha_a$). <i>tc</i> =2: One tailed test ($\alpha_c \geq \alpha_a$). <i>tc</i> =4: Two tailed test ($\alpha_c = \alpha_a$). Code combinations are not allowed.
/WSTR=waveListString	Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsDunnettTest inputs are two or more 1D numeric waves (one wave for each group of samples). The input waves may contain different number of points, but they must contain two or more valid entries per wave.

For output to a table (using /T), each labelled row represents the results of the test for comparing the means of one group to the control group, and rows are ordered so that all comparisons are computed sequentially starting with the group having the smallest mean. The contents of the labelled columns are: the first contains the difference between the group means; the second contains SE (which is computed for possibly unequal number of points); the third contains the *q* statistic for the pair which may be positive or negative; the fourth column contains the critical *q'* value; and the fifth contains 0 if the conclusion is to reject H_0 or 1 for accepting H_0 .

V_flag will be set to -1 for any error and to zero otherwise.

StatsErlangCDF

StatsErlangCDF(*x*, *b*, *c*)

The StatsErlangCDF function returns the Erlang cumulative distribution function

$$F(x, b, c) = 1 - \frac{\Gamma\left(c, \frac{x}{b}\right)}{\Gamma(c)}$$

where $b > 0$ (also as $\lambda = 1/b$) is the scale parameter, $c > 0$ the shape parameter, $\Gamma(x)$ the **gamma** function, and $\Gamma(a, x)$ the incomplete gamma function **gammaInc**.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsErlangPDF**.

StatsErlangPDF

StatsErlangPDF(*x*, *b*, *c*)

The StatsErlangPDF function returns the Erlang probability distribution function

$$f(x, b, c) = \frac{\left(\frac{x}{b}\right)^{c-1} \exp\left(-\frac{x}{b}\right)}{b(c-1)!} \text{ where } b > 0 \text{ (also as } \lambda = 1/b \text{) is the scale parameter and } c > 0 \text{ the shape parameter.}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsErlangCDF**.

StatsErrorPDF

StatsErrorPDF(x, a, b, c)

The StatsErrorPDF function returns the error probability distribution function or the exponential power distribution

$$f(x; a, b, c) = \frac{\exp\left[-\frac{1}{2}\left(\frac{|x-a|}{b}\right)^{\frac{2}{c}}\right]}{b 2^{\frac{c}{2}+1} \Gamma\left(1 + \frac{c}{2}\right)}$$

where a is the location parameter, $b > 0$ is the scale parameter, $c > 0$ is the shape parameter, and $\Gamma(x)$ is the **gamma** function.

See Also

Chapter III-12, **Statistics** for a function and operation overview.

StatsEValueCDF

StatsEValueCDF(x, α, σ)

The StatsEValueCDF function returns the extreme-value (type I, Gumbel) cumulative distribution function

$$F(x; \mu, \sigma) = 1 - \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

where $\sigma > 0$. This is also known as the “minimum” form or distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of σ .

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsEValuePDF** and **StatsInvEValueCDF**.

StatsEValuePDF

StatsEValuePDF(x, α, σ)

The StatsEValuePDF function returns the extreme-value (type I, Gumbel) probability distribution function

$$f(x; \mu, \sigma) = \frac{1}{\sigma} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

where $\sigma > 0$. This is also known as the “minimum” form or the distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of σ .

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsEValueCDF** and **StatsInvEValueCDF**.

StatsExpCDF

StatsExpCDF(x, α, σ)

The StatsExpCDF function returns the exponential cumulative distribution function

$$F(x; \mu, \sigma) = 1 - \exp\left(-\frac{x - \mu}{\sigma}\right) \text{ where } x \geq \mu \text{ and } \sigma > 0. \text{ It returns NaN for } \sigma = 0.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpPDF** and **StatsInvExpCDF**.

StatsExpPDF

StatsExpPDF(x, α, σ)

The StatsExpPDF function returns the exponential probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{\sigma} \exp\left(-\frac{x - \mu}{\sigma}\right)$$

where μ is the location parameter and $\sigma > 0$ is the scale parameter. Use $\mu=0$ and $\sigma=1$ for the standard form of the exponential distribution. It returns NaN for $\sigma=0$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpCDF** and **StatsInvExpCDF**.

StatsFCDF**StatsFCDF(*x*, *n1*, *n2*)**

The StatsFCDF function returns the cumulative distribution function for the F distribution with shape parameters *n1* and *n2*

$$F(x, n_1, n_2) = 1 - \text{BetaI}\left(\frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_2 + n_1 x}\right) \text{ where BetaI is the incomplete beta function.}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFPDF** and **StatsInvFCDF**.

StatsFPDF**StatsFPDF(*x*, *n1*, *n2*)**

The StatsFPDF function returns the probability distribution function for the F distribution with shape parameters *n1* and *n2*

$$f(x, n_1, n_2) = \frac{\Gamma\left(\frac{n_1 + n_2}{2}\right) \left(\frac{n_1}{n_2}\right)^{\frac{n_1}{2}} x^{\frac{n_1}{2} - 1}}{\Gamma\left(\frac{n_1}{2}\right) \Gamma\left(\frac{n_2}{2}\right) \left(1 + \frac{n_1 x}{n_2}\right)^{\frac{n_1 + n_2}{2}}}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFCDF** and **StatsInvFCDF**.

StatsFriedmanCDF**StatsFriedmanCDF(*x*, *n*, *m*, *method*, *useTable*)**

The StatsFriedmanCDF function returns the cumulative probability distribution of the Friedman distribution with *n* rows and *m* columns. The exact Friedman distribution is computationally intensive, taking on the order of $(n!)^m$ iterations. You may be able to use a range of precomputed exact values by passing a nonzero value for *useTable*, which will use *method* only if the value is not in the table. For large *m*, consider using the Chi-squared or the Monte-Carlo approximations. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

<i>method</i>	What It Does
0	Exact computation.
1	Chi-square approximation.
2	Monte-Carlo approximation.
3	Use built-table only and return NaN if not in table.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvFriedmanCDF** and **StatsFriedmanTest**.

StatsFriedmanTest

StatsFriedmanTest [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsFriedmanTest operation performs Friedman's test on a randomized block of data. It is a nonparametric analysis of data contained in either individual 1D waves or in a single 2D wave. Output is to the M_FriedmanTestResults wave in the current data folder or optionally to a table.

Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /Q No results printed in the history area.
- /RW Saves the ranking wave M_FriedmanRanks, which contains the rank values corresponding to each input datum.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 - k*=0: Normal with dialog (default).
 - k*=1: Kills with no dialog.
 - k*=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.
- /WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
- /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The Friedman test ranks the input data on a row-by-row basis, sums the ranks for each column, and computes the Friedman statistic, which is proportional to the sum of the squares of the ranks.

Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. All 1D waves must have the same number of points. A 2D wave must not contain any NaNs.

The critical value for the Friedman distribution is fairly difficult to compute when the number of rows and columns is large because it requires a number of permutations on the order of $(\text{numColumns!})^{\text{numRows}}$. A certain range of these critical values are supported by precomputed tables. When the exact critical value is not available you can use one of the two approximations that are always computed: the Chi-squared approximation or the Iman and Davenport approximation, which converts the Friedman statistic is converted to a new value *Ff* then compares it with critical values from the F distribution using weighted degrees of freedom.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Friedman statistic, the exact critical value (if available), the Chi-squared approximation, the Iman and Davenport approximation, and the conclusion (1 to accept H_0 and 0 to reject it).

V_flag will be set to -1 for any error and to zero otherwise.

References

Iman, R.L., and J.M. Davenport, Approximations of the critical region of the Friedman statistic, *Comm. Statist. A9*, 571-595, 1980.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFriedmanCDF** and **StatsInvFriedmanCDF**.

StatsFTest

StatsFTest [*flags*] *wave1*, *wave2*

The StatsFTest operation performs the F-test on the two distributions in *wave1* and *wave2*, which can be any real numeric type, must contain at least two data points each, and can have an arbitrary number of dimensions. Output is to the W_StatsFTest wave in the current data folder or optionally to a table.

Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /Q No results printed in the history area.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.

$k=0$: Normal with dialog (default).
 $k=1$: Kills with no dialog.
 $k=2$: Disables killing.
 $/TAIL=tc$ Specifies the tail tested.
 $tc=1$: Lower one-tail test with H_a : $\sigma_1 > \sigma_2$.
 $tc=2$: Upper one-tail test with H_a : $\sigma_1 < \sigma_2$.
 $tc=4$: Default; the null hypothesis H_0 : $\sigma_1 = \sigma_2$ with H_a : $\sigma_1 \neq \sigma_2$.
 $/Z$ Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The F statistic is the ratio of the variance of *wave1* to the variance of *wave2*. We assume the waves have equal wave variances and that H_0 is $\sigma_1 = \sigma_2$. For the upper one-tail test we reject H_0 if F is greater than the upper critical value or if F is smaller than the lower critical value in the lower one-tail test. In the two-tailed test we reject H_0 if F is either greater than the upper critical value or smaller than the lower critical value. The critical values are computed by numerically solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x, n_1, n_2) = 1 - \text{betain}\left(\frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_2 + n_1 x}\right)$$

where the degrees of freedom n_1 and n_2 equal the number of valid (non-NaN) points in each wave -1, and *betain* is the incomplete beta function. To get the critical value for the upper one-tail test we solve $F(x) = 1 - \alpha$. For the lower one-tail test we solve $F(x) = \alpha$. In the two-tailed test the lower critical value is a solution for $F(x) = \alpha/2$ and the upper critical value is a solution for $F(x) = 1 - \alpha/2$.

The F-test requires that the two samples are from normally distributed populations.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsVariancesTest**, **StatsFCDF**, and **betain**.

StatsGammaCDF

StatsGammaCDF(*x*, α , σ , γ)

The StatsGammaCDF function returns the gamma cumulative distribution function

$$F(x, \mu, \sigma, \gamma) = \frac{\Gamma_{inc}\left(\gamma, \frac{x - \mu}{\sigma}\right)}{\Gamma(\gamma)}, \quad \begin{matrix} x \geq \mu \\ \sigma, \gamma > 0 \end{matrix}$$

where Γ is the gamma function and Γ_{inc} is the incomplete gamma function **gammaInc**.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaPDF** and **StatsInvGammaCDF**.

StatsGammaPDF

StatsGammaPDF(*x*, α , σ , γ)

The StatsGammaPDF function returns the gamma probability distribution function

$$f(x, \mu, \sigma, \gamma) = \frac{\left(\frac{x - \mu}{\sigma}\right)^{\gamma-1} \exp\left(-\frac{x - \mu}{\sigma}\right)}{\sigma \Gamma(\gamma)}, \quad \begin{matrix} x \geq \mu \\ \sigma, \gamma > 0 \end{matrix}$$

where α is the location parameter, σ is the scale parameter, γ is the shape parameter, and Γ is the gamma function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaCDF** and **StatsInvGammaCDF**.

StatsGeometricCDF

StatsGeometricCDF(*x*, *p*)

The StatsGeometricCDF function returns the geometric cumulative distribution function

$F(x,p) = 1 - (1-p)^{x+1}$ where p is the probability of success in a single trial and x is the number of trials for $x \geq 0$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricPDF** and **StatsInvGeometricCDF**.

StatsGeometricPDF

StatsGeometricPDF(*x*, *p*)

The StatsGeometricPDF function returns the geometric probability distribution function

$F(x,p) = p(1-p)^x$ where the p is the probability of success in a single trial and x is the number of trials $x \geq 0$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricCDF** and **StatsInvGeometricCDF**.

StatsHodgesAjneTest

StatsHodgesAjneTest [*flags*] *srcWave*

The StatsHodgesAjneTest operation performs the Hodges-Ajne nonparametric test for uniform distribution around a circle. Output is to the W_HodgesAjne wave in the current data folder or optionally to a table.

Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/SA= <i>specAngle</i>	Uses the Batschelet modification of the Hodges-Ajne test to test for uniformity against the alternative of concentration around the specified angle. <i>specAngle</i> must be expressed in radians modulus 2π .
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The input *srcWave* must contain angles in radians, can be any number of dimensions, can be single or double precision, and should not contain NaNs or INFs.

StatsHodgesAjneTest performs the standard Hodges-Ajne test, which simply tests for uniformity against the hypothesis that the population is not uniformly distributed around the circle. This test finds a diameter that divides the circle into two halves such that one contains the least number of data m , the test statistic.

Use /SA to perform the modified (Batschelet) test, which tests against the alternative that the population is concentrated somehow about the specified angle. The modified test counts the number of points m' in 90-degree neighborhoods around the specified angle. The test statistic is given by $C=n-m'$ where n is the number of points in the wave. The critical value is computed from the binomial probability density.

In both cases H_0 is rejected if the statistic is smaller than the critical value.

V_flag will be set to -1 for any error and to zero otherwise.

StatsHyperGCDF

StatsHyperGCDF(*x*, *m*, *n*, *k*)

The StatsHyperGCDF function returns the hypergeometric cumulative distribution function, which is the probability of getting *x* marked items when drawing (without replacement) *k* items out of a population of *m* items when *n* out of the *m* are marked.

Details

The hypergeometric distribution is

$$F(x, m, n, k) = \sum_{L=0}^x \frac{\binom{n}{L} \binom{m-L}{k-L}}{\binom{m}{k}}$$

where $\binom{a}{b}$ is the **binomial** function. All parameters must be positive integers and must have $m > n$ and $x < k$; otherwise it returns NaN.

Chapter III-12, **Statistics** for a function and operation overview; **StatsHyperGPDF**.

StatsHyperGPDF

StatsHyperGPDF(*x*, *m*, *n*, *k*)

The StatsHyperGPDF function returns the hypergeometric probability distribution function, which is the probability of getting *x* marked items when drawing without replacement *k* items out of a population of *m* items where *n* out of the *m* are marked.

Details

The hypergeometric distribution is

$$f(x, m, n, k) = \frac{\binom{n}{x} \binom{m-n}{k-x}}{\binom{m}{k}}$$

where $\binom{a}{b}$ is the **binomial** function. All parameters must be positive integers and must have $m > n$ and $x < k$.

Chapter III-12, **Statistics** for a function and operation overview; **StatsHyperGCDF**.

StatsInvBetaCDF

StatsInvBetaCDF(*cdf*, *p*, *q* [, *a*, *b*])

The StatsInvBetaCDF function returns the inverse of the beta cumulative distribution function. There is no closed form expression for the inverse beta CDF; it is evaluated numerically.

The defaults (*a*=0 and *b*=1) correspond to the standard beta distribution.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsBetaCDF** and **StatsBetaPDF**.

StatsInvBinomialCDF**StatsInvBinomialCDF(cdf, p, N)**

The StatsInvBinomialCDF function returns the inverse of the binomial cumulative distribution function. The inverse function returns the value at which the binomial CDF with probability p and total elements N , has the value 0.95. There is no closed form expression for the inverse binomial CDF; it is evaluated numerically.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsBinomialCDF** and **StatsBinomialPDF**.

StatsInvCauchyCDF**StatsInvCauchyCDF(cdf, α , σ)**

The StatsInvCauchyCDF function returns the inverse of the Cauchy-Lorentz cumulative distribution function

$$x = \mu + \sigma \tan \left[\pi \left(cdf - \frac{1}{2} \right) \right]$$

It returns NaN for $cdf < 0$ or $cdf > 1$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsCauchyPDF**.

StatsInvChiCDF**StatsInvChiCDF(x, n)**

The StatsInvChiCDF function returns the inverse of the chi-squared distribution of x and shape parameter n . The inverse of the distribution is also known as the percent point function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiCDF** and **StatsChiPDF**.

StatsInvCMSSDCDF**StatsInvCMSSDCDF(cdf, n)**

The StatsInvCMSSDCDF function returns the critical values of the C distribution (mean square successive difference), which is

$$f(C, n) = \frac{\Gamma(2m+2)}{a^{2m+1} [\Gamma(m+1)]^2} \left(1 - \frac{C^2}{a^2} \right)^m \quad \text{where} \quad a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)}, \quad m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}.$$

Critical values are computed from the integral of the probability distribution function.

Young, L.C., On randomness in ordered sequences, *Annals of Mathematical Statistics*, 12, 153-162, 1941.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsCMSSDCDF** and **StatsSRTest**.

StatsInvDExpCDF**StatsInvDExpCdf(cdf, α , σ)**

The StatsInvDExpCdf function returns the inverse of the double-exponential cumulative distribution function

$$\begin{aligned} \alpha + \sigma \ln(2cdf) & \quad cdf < 0.5 \\ \alpha - \sigma \ln(2(1 - cdf)) & \quad cdf \geq 0.5 \end{aligned}$$

StatsInvEValueCDF

It returns NaN for $cdf < 0$ or $cdf > 1$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpCDF** and **StatsDExpPDF**.

StatsInvEValueCDF

StatsInvEValueCDF(*cdf*, α , σ)

The StatsInvEValueCDF function returns the inverse of the extreme-value (type I, Gumbel) cumulative distribution function $x = \alpha + \sigma \ln[-\ln(1 - cdf)]$ where $\sigma > 0$. It returns NaN for $cdf < 0$ or $cdf > 1$. This inverse applies to the “minimum” form of the distribution. Reverse the sign of σ to obtain the inverse distribution of the maximum form.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsEValueCDF** and **StatsEValuePDF**.

StatsInvExpCDF

StatsInvExpCDF(*cdf*, α , σ)

The StatsInvExpCDF function returns the inverse of the exponential cumulative distribution function $x = -\sigma \ln(1 - cdf)$.

It returns NaN for $cdf < 0$ or $cdf > 1$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpCDF** and **StatsExpPDF**.

StatsInvFCDF

StatsInvFCDF(*x*, *n1*, *n2*)

The StatsInvFCDF function returns the inverse of the F distribution cumulative distribution function for x and shape parameters $n1$ and $n2$. The inverse is also known as the percent point function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFCDF** and **StatsFPDF**.

StatsInvFriedmanCDF

StatsInvFriedmanCDF(*cdf*, *n*, *m*, *method*, *useTable*)

The StatsInvFriedmanCDF function returns the inverse of the Friedman distribution cumulative distribution function of cdf with n rows and m columns. Use this typically to compute the critical values of the distribution

`Print StatsInvFriedmanCDF(1-alpha,n,m,0,1)`

where alpha is the significance level of the associated test.

The complexity of the computation of Friedman CDF is on the order of $(n!)^m$. For nonzero values of *useTable*, searches are limited to the built-in table for distribution values. If n and m are not in the table the calculation may still proceed according to the *method*.

<i>method</i>	What It Does
0	Exact computation(slow, not recommended).
1	Chi-square approximation.
2	Monte-Carlo approximation (slow).
3	Use built-in table only and return a NaN if not in table.

For large m and n , consider using the Chi-squared or the Iman and Davenport approximations. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*).

Note: Table values are different from computed values for both methods. Table values use more conservative criteria than computed values. Table values are more consistent with published values because the Friedman distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found.

Precomputed tables use these values:

<i>n</i>	<i>m</i>
3	2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16
4	2, 3, 4, 5, 6, 7, 8, 9
5	2, 3, 4, 5, 6
6	2, 3, 4, 5
7	2, 3, 4
8	2, 3
9	2, 3

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFriedmanCDF** and **StatsFriedmanTest**.

StatsInvGammaCDF

StatsInvGammaCDF(cdf, α , σ , γ)

The StatsInvGammaCDF function returns the inverse of the gamma cumulative distribution function. There is no closed form expression for the inverse gamma distribution; it is evaluated numerically.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaCDF** and **StatsGammaPDF**.

StatsInvGeometricCDF

StatsInvGeometricCDF(cdf, p)

The StatsInvGeometricCDF function returns the inverse of the geometric cumulative distribution function

$$x = \frac{\ln(1 - \text{cdf})}{\ln(1 - p)} - 1 \text{ where } p \text{ is the probability of success in a single trial and } x \text{ is the number of trials.}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricCDF** and **StatsGeometricPDF**.

StatsInvKuiperCDF

StatsInvKuiperCDF(cdf)

The StatsInvKuiperCDF function returns the inverse of Kuiper cumulative distribution function.

There is no closed form expression. It is mapped to the range of 0.4 to 4, with accuracy of 1e-10.

References

See in particular Section 14.3 of

Press, William H., et al., *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsKuiperCDF**.

StatsInvLogisticCDF

StatsInvLogisticCDF(cdf, a, b)

The StatsInvLogisticCDF function returns the inverse of the logistic cumulative distribution function

$x = a + b \log \left(\frac{cdf}{1-cdf} \right)$ where the scale parameter $b > 0$ and the shape parameter is a .

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogisticCDF** and **StatsLogisticPDF** functions.

StatsInvLogNormalCDF

StatsInvLogNormalCDF(cdf, α, σ, γ)

The StatsInvLogNormalCDF function returns the numerically evaluated inverse of the lognormal cumulative distribution function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalCDF** and **StatsLogNormalPDF** functions.

StatsInvMaxwellCDF

StatsInvMaxwellCDF(cdf, k)

The StatsInvMaxwellCDF function returns the evaluated numerically inverse of the Maxwell cumulative distribution function. There is no closed form expression.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellCDF** and **StatsMaxwellPDF** functions.

StatsInvMooreCDF

StatsInvMooreCDF(cdf, N)

The StatsInvMooreCDF function returns the inverse cumulative distribution function for Moore's R^* , which is used as a critical value in nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range $3 \leq N \leq 120$ and does not change appreciably for $N > 120$.

The inverse distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

References

Moore, B.R., A modification of the Rayleigh test for vector data, *Biometrika*, 67, 175-180, 1980.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsCircularMeans** function.

StatsInvNBinomialCDF

StatsInvNBinomialCDF(cdf, k, p)

The StatsInvNBinomialCDF function returns the numerically evaluated inverse of the negative binomial cumulative distribution function. There is no closed form expression.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialCDF** and **StatsNBinomialPDF** functions.

StatsInvNCChiCDF

StatsInvNCChiCDF(cdf, n, d)

The StatsInvNCChiCDF function returns the inverse of the noncentral chi-squared cumulative distribution function. It is computationally intensive because the inverse is computed numerically and involves multiple evaluations of the noncentral distribution, which is evaluated from a series expansion.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCChiCDF**, **StatsNCChiPDF**, **StatsChiCDF**, and **StatsChiPDF** functions.

StatsInvNCFCDF

StatsInvNCFCDF(cdf, n1, n2, d)

The StatsInvNCFCDF function returns the numerically evaluated inverse of the cumulative distribution function of the noncentral F distribution. *n1* and *n2* are the shape parameters and *d* is the noncentrality measure. There is no closed form expression for the inverse.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCFCDF** and **StatsNCFPDF** functions.

StatsInvNormalCDF

StatsInvNormalCDF(cdf, m, s)

The StatsInvNormalCDF function returns the numerically computed inverse of the normal cumulative distribution function. There is no closed form expression.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalCDF** and **StatsNormalPDF** functions.

StatsInvParetoCDF

StatsInvParetoCDF(cdf, a, c)

The StatsInvParetoCDF function returns the inverse of the Pareto cumulative distribution function

$$x = \frac{a}{(1 - cdf)^{(1/c)}}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoCDF** and **StatsParetoPDF** functions.

StatsInvPoissonCDF

StatsInvPoissonCDF(cdf, λ)

The StatsInvPoissonCDF function returns the numerically evaluated inverse of the Poisson cumulative distribution function. There is no closed form expression for the inverse Poisson distribution.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonCDF** and **StatsPoissonPDF** functions.

StatsInvPowerCDF

StatsInvPowerCDF(cdf, b, c)

The StatsInvPowerCDF function returns the inverse of the Power Function cumulative distribution function $x = b \cdot cdf^{(1/c)}$ where the scale parameter *b* and the shape parameter *c* satisfy $b, c > 0$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerCDF** and **StatsPowerPDF** functions.

StatsInvQCDF

StatsInvQCDF(cdf, r, c, df)

The StatsInvQCDF function returns the critical value of the Q cumulative distribution function for *r* the number of groups, *c* the number of treatments, and *df* the error degrees of freedom ($df = r * c * (n - 1)$ with sample size *n*).

Details

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use $r=1$.

Examples

The critical value for a Tukey test comparing 5 treatments with 6 samples and 0.05 significance is:

```
Print StatsInvQpCDF(1-0.05,1,5,5*(6-1))
```

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTukeyTest** function.

StatsInvQpCDF

StatsInvQpCDF(*ng*, *nt*, *df*, *alpha*, *side*, *sSizeWave*)

The StatsInvQpCDF function returns the critical value of the Q' cumulative distribution function for *ng* the number of groups, *nt* the number of treatments, and *df* the error degrees of freedom. *side*=1 for upper-tail or *side*=2 for two-tailed critical values.

sSizeWave is an integer wave of *ng* columns and *nt* rows specifying the number of samples in each treatment. If *sSizeWave* is a null wave (\$" ") StatsInvQpCDF computes the number of samples from $df=ng*nt*(n-1)$ with *n* truncated to an integer.

Details

StatsInvQpCDF is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment.

StatsInvQpCDF differs from other StatsInvXXX functions in that you do not specify a *cdf* value for the inverse (usually $1-\alpha$ for the critical value). Here *alpha* selects one- or two-tailed critical values.

It is computationally intensive, taking longer to execute for smaller *alpha* values.

Examples

The critical value for a Dunnett test comparing 4 treatments with 4 samples and (upper tail) 0.05 significance is:

```
// here n=4 because 12=1*4*(4-1).
Print StatsInvQpCDF(1,4,12,0.05,1,$" ")
2.28734
```

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsDunnettTest** and **StatsInvQpCDF** functions.

StatsInvRayleighCdf

StatsInvRayleighCdf(*cdf* [, *s* [, *m*]])

The **StatsInvRayleighCdf** function returns the inverse of the Rayleigh cumulative distribution function $x = \alpha + \sigma\sqrt{-2\ln(1-cdf)}$ with defaults *s*=1 and *m*=0. It returns NaN for $s \leq 0$ and zero for $x \leq m$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighCDF** and **StatsRayleighPDF** functions.

StatsInvRectangularCDF

StatsInvRectangularCDF(*cdf*, *a*, *b*)

The StatsInvRectangularCDF function returns the inverse of the rectangular (uniform) cumulative distribution function $x = a + cdf(b-a)$ where $a < b$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularCDF** and **StatsRectangularPDF** functions.

StatsInvSpearmanCDF

StatsInvSpearmanCDF(*cdf*, *N*)

The StatsInvSpearmanCDF function returns the inverse cumulative distribution function for Spearman's r , which is used as a critical value in rank correlation tests.

The inverse distribution is computed by finding the value of r for which it attains the *cdf* value. The result is usually lower than in published tables, which are more conservative when the first derivative of the distribution is discontinuous.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest**, **StatsSpearmanRhoCDF**, and **StatsKendallTauTest** functions.

StatsInvStudentCDF

StatsInvStudentCDF(*cdf*, *n*)

The StatsInvStudentCDF function returns the numerically evaluated inverse of Student cumulative distribution function. There is no closed form expression.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentCDF** and **StatsStudentPDF** functions.

StatsInvTopDownCDF

StatsInvTopDownCDF(*cdf*, *N*)

The StatsInvTopDownCDF function returns the inverse cumulative distribution function for the top-down distribution. For $3 \leq N \leq 7$ it uses a lookup table CDF and returns the next higher value of r for which the distribution value is larger than *cdf*. For $8 \leq N \leq 50$ it returns the nearest value for which the built-in distribution returns *cdf*. For $N > 50$ it returns the scaled normal approximation.

Tabulated values are from Iman and Conover who pick as the critical value the very first transition of the distribution following the specified *cdf* value. These tabulated values tend to be slightly higher than calculated values for $7 < N < 15$.

References

Iman, R.L., and W.J. Conover, A measure of top-down correlation, *Technometrics*, 29, 351-357, 1987.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest** and **StatsTopDownCDF** functions.

StatsInvTriangularCDF

StatsInvTriangularCDF(*cdf*, *a*, *b*, *c*)

The StatsInvTriangularCDF function returns the inverse of the triangular cumulative distribution function

$$x = \begin{cases} a + \sqrt{cdf(b-a)(c-a)} & 0 \leq cdf \leq \frac{c-a}{b-a} \\ b - \sqrt{(1-cdf)(b-a)(b-c)} & \frac{c-a}{b-a} \leq cdf \leq 1 \end{cases}$$

where $a < c < b$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularCDF** and **StatsTriangularPDF** functions.

StatsInvUSquaredCDF

StatsInvUSquaredCDF(*cdf*, *n*, *m*, *method*, *useTable*)

The StatsInvUSquaredCDF function returns the inverse of Watson's U^2 cumulative distribution function integer sample sizes n and m . Use a nonzero value for *useTable* to search a built-in table of values. If n and m cannot be found in the table, it will proceed according to *method*:

<i>method</i>	What It Does
0	Exact computation using Burr algorithm (could be slow).
1	Tiku approximation using chi-squared.
2	Use built-in table only and return a NaN if not in table.

For large n and m , consider using the Tiku approximation. To abort execution, press Command-period (*Macintosh*) or Ctrl+Break (*Windows*). Because n and m are interchangeable, n should always be the smaller value. For $n > 8$ the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with m values exceeding these limits.

The inverse is obtained from precomputed tables of Watson's U^2 (see **StatsUSquaredCDF**).

Note: Table values are different from computed values. These values use more conservative criteria than computed values. Table values are more consistent with published values because the U^2 distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found. See **StatsInvFriedmanCDF**.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWatsonUSquaredTest** and **StatsUSquaredCDF** functions.

StatsInvVonMisesCDF

StatsInvVonMisesCDF(*cdf*, *a*, *b*)

The StatsInvVonMisesCDF function returns the numerically evaluated inverse of the von Mises cumulative distribution function where the value of the integral of the distribution matches *cdf*. Parameters are as for **StatsVonMisesCDF**.

References

Evans, M., N. Hastings, and B. Peacock, *Statistical Distributions*, 3rd ed., Wiley, New York, 2000.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsVonMisesPDF** and **StatsVonMisesNoise** functions.

StatsInvWeibullCDF

StatsInvWeibullCDF(*cdf*, *m*, *s*, *g*)

The StatsInvWeibullCDF function returns the inverse of the Weibull cumulative distribution function

$$x = \mu + \sigma \left[-\ln(1 - cdf) \right]^{1/\gamma}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWeibullCDF** and **StatsWeibullPDF** functions.

StatsJBTest

StatsJBTest [*flags*] *srcWave*

The StatsJBTest operation performs the Jarque-Bera test on *srcWave*. Output is to the W_JBResults wave in the current data folder.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).

/Q No results printed in the history area.
 /T=k Displays results in a table. k specifies the table behavior when it is closed.
 $k=0$: Normal with dialog (default).
 $k=1$: Kills with no dialog.
 $k=2$: Disables killing.
 /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsJBTest computes the Jarque-Bera statistic

$$JB = \frac{n}{6} \left(S^2 + \frac{K^2}{4} \right)$$

where S is the skewness, K is the kurtosis, and n is the number of points in the input wave. We can express S and K terms of the j th moment of the distribution for n samples X_i

$$\mu_j = \frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^j \text{ as } S = \frac{\mu_3}{(\mu_2)^{3/2}} \text{ and } K = \frac{\mu_4}{(\mu_2)^2} - 3.$$

The Jarque-Bera statistic is asymptotically distributed as a Chi-squared with two degrees of freedom. For values of n in the range [7,2000] the operation provides critical values obtained from Monte-Carlo simulations. For further details or if you would like to run your own simulation to obtain critical values for other values of n , use the JarqueBeraSimulation example experiment.

StatsJBTest reports the number of finite data points, skewness, kurtosis, Jarque-Bera statistic, asymptotic critical value, and the critical value obtained from Monte-Carlo calculations as appropriate; it ignores NaNs and INFs.

Jarque, C., and A. Bera, A test of normality of observations and regression residuals, *International Statistical Review*, 55, 163-172, 1987.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsKSTest**, **WaveStats**, and **StatsCircularMoments**.

StatsKendallTauTest

StatsKendallTauTest [*flags*] *wave1* [, *wave2*]

The StatsKendallTauTest operation performs the nonparametric Mann-Kendall test, which computes a correlation coefficient τ (similar to Spearman's correlation) from the relative order of the ranks of the data. Output is to the W_StatsKendallTauTest wave in the current data folder.

Flags

/Q No results printed in the history area.
 /T=k Displays results in a table. k specifies the table behavior when it is closed.
 $k=0$: Normal with dialog (default).
 $k=1$: Kills with no dialog.
 $k=2$: Disables killing.
 /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Inputs may be a pair of XY (1D) waves of any real numeric type or a single 1D wave, which is equivalent to using a pair of XY waves where the X wave is monotonically increasing function of the point number. StatsKendallTauTest ignores wave scaling.

Kendall's τ is 1 for a monotonically increasing input and -1 for monotonically decreasing input. The significance of the test is computed from the normal approximation

$$Var(\tau) = \frac{4n+10}{9n(n-1)}$$

where n is the number of data points in each wave. The significance is expressed as a P-value for the null hypothesis of no correlation.

References

Kendall, M.G., *Rank Correlation Methods*, 3rd ed., Griffin, London, 1962.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsRankCorrelationTest**.

For small values of n you can compute the exact probability using the procedure `WM_KendallSProbability()`.

StatsKSTest

StatsKSTest [*flags*] *srcWave* [, *distWave*]

The StatsKSTest operation performs the Kolmogorov-Smirnov (KS) goodness-of-fit test for two continuous distributions. The first distribution is *srcWave* and the second distribution can be expressed either as the optional wave *distWave* or as a user function with `/CDFF`. Output is to the `W_KSResults` wave in the current data folder.

Flags

<code>/ALPH = val</code>	Sets the significance level (default <i>val</i> =0.05).
<code>/CDFF=func</code>	Specifies a user function expressing the cumulative distribution function. See Details.
<code>/Q</code>	No results printed in the history area.
<code>/T=k</code>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
<code>/Z</code>	Ignores errors. <code>V_flag</code> will be set to -1 for any error and to zero otherwise.

Details

The Kolmogorov-Smirnov (KS) goodness-of-fit test applies only to continuous distributions and cases where the compared distribution (expressed as a user function) is completely specified without estimating parameters from the data. It compares the cumulative distribution function (CDF) of two distributions and sets the test statistic *D* to the largest difference between the CDFs. Because CDFs are in the range [0,1], *D* is also bound by this range.

When specifying the distributions with two waves, StatsKSTest first sorts the data in the waves and then computes the CDFs and *D*. You can also specify one of the distributions with a user function. For example, the following function tests if the data in *srcWave* is normally distributed with zero mean and `stdv=5`:

```
Function getUserCDF(inX)
    Variable inX
    return statsNormalCDF(inX,0,5)
End
```

Outputs are the number of elements, the KS statistic *D*, and the critical value. When both distributions are specified by waves, the number of elements is the weighted value $(n1*n2)/(n1+n2)$.

References

Critical values are based on:

Birnbaum, Z. W., and Fred H. Tingey, One-sided confidence contours for probability distribution functions, *The Annals of Mathematical Statistics*, 22, 592–596, 1951.

A statistically more powerful modification of the classic KS test can be found in:

Khamis, H.J., The two-stage delta-corrected Kolmogorov-Smirnov test, *Journal of Applied Statistics*, 27, 439–450, 2000.

StatsKSTest implements the original KS test. The difficulty in implementing the modified tests for all the cases defined by Stephens is in obtaining the critical values which have to be derived by time consuming Monte-Carlo simulations.

Critiques can be found in:

D'Agostino, R.B., and M. Stephens, eds., *Goodness-Of-Fit Techniques*, Marcel Dekker, New York, 1986.

NIST/SEMATECH, Kolmogorov-Smirnov Goodness-of-Fit Test, in *NIST/SEMATECH e-Handbook of Statistical Methods*,
<http://www.itl.nist.gov/div898/handbook/eda/section3/eda35g.htm>, 2005.

Chapter III-12, **Statistics** for a function and operation overview; **StatsJBTest**, **WaveStats**, and **StatsCircularMoments**.

StatsKuiperCDF

StatsKuiperCDF (V)

The StatsKuiperCDF function returns the Kuiper cumulative distribution function

$$F(V) = 1 - 2 \sum_{j=1}^{\infty} (4/j^2 V^2 - 1) \exp(-2/j^2 V^2)$$

Accuracy is on the order of 1e-15. It returns 0 for values of $V < 0.4$ or 1 for $V > 3.1$.

Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvKuiperCDF**.

StatsKWTest

StatsKWTest [flags] [wave1, wave2,... wave100]

The StatsKWTest operation performs the nonparametric Kruskal-Wallis test which tests variances using the ranks of the data. Output is to the W_KWTestResults wave in the current data folder.

Flags

- /ALPH = val Sets the significance level (default val=0.05).
- /E Computes the exact P-value using the Klotz and Teng algorithm, which may require long computation times for large data sets. You can stop the calculation by pressing Command-period (*Macintosh*) or Ctrl+Break (*Windows*) after which all remaining results remain valid and the exact P-value is set to NaN.
- /Q No results printed in the history area.
- /T=k Displays results in a table. k specifies the table behavior when it is closed.
 - k=0: Normal with dialog (default).
 - k=1: Kills with no dialog.
 - k=2: Disables killing.
- /WSTR=waveListString Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
- /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Inputs are two or more 1D numerical waves (one for each group of samples). Use NaNs for missing data or use waves with different number of points.

StatsKWTest always computes the critical values using both the Chi-squared and Wallace approximations. If appropriate (small enough data set) you can also use /E to obtain the exact P value. When the calculation involves many waves or many data points the calculation of the exact critical value can be very lengthy. All the results are saved in the wave W_KWTestResults in the current data folder and are optionally displayed in a table (/T). The wave contains the following information:

H_0 for the Kruskal-Wallis test is that all input waves are the same. If the test fails and the input consisted of more than two waves, there is no indication for possible agreement between some of the waves. See **StatsNPMCTest** for further analysis.

V_flag will be set to -1 for any error and to zero otherwise.

Row	Data
0	Number of groups
1	Number of valid data points (excludes NaNs)
2	Alpha
3	Kruskal-Wallis Statistic H
4	Chi-squared approximation for the critical value Hc
5	Chi-squared approximation for the P value
6	Wallace approximation for the critical value Hc
7	Wallace approximation for the P value
8	Exact P value (requires /E)

StatsLinearCorrelationTest

StatsLinearCorrelationTest [flags] waveA, waveB

The StatsLinearCorrelationTest operation performs correlation tests on *waveA* and *waveB*, which must be real valued numeric waves and must have the same number of points. Output is to the W_StatsLinearCorrelationTest wave in the current data folder or optionally to a table.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).
/CI computes confidence intervals for the correlation coefficient.
/Q No results printed in the history area.
/RHO=*rhoValue* Tests hypothesis that the correlation has a nonzero value $|r| \leq 1$.
/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.
/Z Ignores errors.

Details

The linear correlation tests start by computing the linear correlation coefficient for the *n* elements of both waves:

$$r = \frac{\sum_{i=1}^n X_i Y_i - \frac{1}{n} \sum_{i=1}^n X_i \sum_{i=1}^n Y_i}{\sqrt{\left(\sum_{i=1}^n X_i^2 - \frac{1}{n} \left(\sum_{i=1}^n X_i \right)^2 \right) \left(\sum_{i=1}^n Y_i^2 - \frac{1}{n} \left(\sum_{i=1}^n Y_i \right)^2 \right)}}$$

Next it computes the standard error of the correlation coefficient $sr = \sqrt{\frac{1-r^2}{n-2}}$

The basic test is for hypothesis H_0 : the correlation coefficient is zero, in which case t and F statistics are applicable. It computes $t=r/sr$, $F=(1+|r|)/(1-|r|)$, and then the critical values for one and two tailed hypotheses (designated by t_{c1} , t_{c2} , F_{c1} , and F_{c2} respectively). Critical value for r are computed using

$$rc_i = \sqrt{\frac{t_c^2}{t_c^2 + n}}$$

where i takes the values 1 or 2 for one and two tailed hypotheses. Finally, it computes the power of the test at the alpha significance level for both one and two tails (Power1 and Power2).

If you use /RHO it uses the Fisher transformation to compute $\text{FisherZ} = \frac{1}{2} \ln\left(\frac{1+r}{1-r}\right)$ and $\text{zeta} = \frac{1}{2} \ln\left(\frac{1+\rho}{1-\rho}\right)$

the standard error approximation $\text{sigmaZ} = \sqrt{1/(n-3)}$ and $\text{Zstatistic} = (\text{FisherZ} - \text{zeta})/\text{sigmaZ}$ and the critical values from the normal distribution Z_{ci} .

The confidence intervals are calculated differently depending on the hypothesis for the value of the correlation coefficient. If /RHO is not used the confidence intervals are computed using the critical value F_{c2} , otherwise they are computed using the critical Z_{c2} and sigmaZ .

Chapter III-12, **Statistics** for a function and operation overview; **StatsCircularCorrelationTest**, **StatsMultiCorrelationTest**, and **StatsRankCorrelationTest**.

StatsLinearRegression

StatsLinearRegression [*flags*] [*wave0*, *wave1*,...]

The StatsLinearRegression operation performs regression analysis on the input wave(s). Output is to the W_StatsLinearRegression wave in the current data folder or optionally to a table. Additionally, the M_DunnettMCElevations, M_TukeyMCSlopes, and M_TukeyMCElevations waves may be created as specified.

Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /B=*beta0* Tests the hypothesis that the slope $b = \text{beta0}$ (default is 0). The results are expressed by the t-statistic, which can be compared with the tc value for the two-tailed test. Get the critical value for a one-tailed test using `StatsStudentCDF(1-alpha, N-2)`. It does not work with /MYVW.
- /BCIW Computes two confidence interval waves for the high side and the low side of the confidence interval. The new waves are named with _CH and _CL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
- /BPIW[=*mAdditional*] Computes prediction interval waves for the high side and the low side of the confidence interval on a single additional measurement (default). Use *mAdditional* to specify additional measurements. The new waves are named with _PH and _PL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
- /DET=*controlIndex* Performs Dunnett's multicomparison test for the elevations. The test requires more than two Y waves for regression, the test for the slopes should not reject the equal slope hypothesis, and the test for the elevations should reject the equal elevation hypothesis. *controlIndex* is the zero-based index of the Y wave representing the control (X waves do not count in the index specification). The test compares the elevation of every Y wave with the specified control.

Output is to the M_DunnettMCElevations wave in the current data folder or optionally to a table. For every Y wave and control Y wave combination, the results include SE, q, q' (shown as qp), and the conclusion with 1 to accept the hypothesis of equal elevations or 0 to reject it. Use /TAIL to determine the critical value and the sense of the test. If you use /TUK you will also get the Tukey test for the set of elevations.

/MYVW={*xWave*, *yWave*}

Specifies that the input consists of multiple Y values for each X value. It ignores all other inputs and the results are appropriate only for multiple Y values at each X point.

yWave is a 2D wave of values arranged in columns. Use NaNs for padding where rows do not have the same number of entries as others. It will use the X scaling of *yWave* when *xWave* is null, /MYVW={*, *yWave*}.

It first tests the hypothesis (H_0) that the population regression is linear in an analysis of variance calculation. It generates results 1-7 (see Details) as well as: Among Groups SS, Among Groups DF, Within Groups SS, Within Groups DF, Deviations from Linearity SS, Deviations from Linearity DF, F statistic defined by the ratio of Deviation from Linearity MS to Within Groups MS, and the critical value F_c .

Next, it tests the hypothesis that the slope $\beta=0$. If the original H_0 was accepted, the new F statistic= $\text{regressionMS}/\text{residualMS}$. Otherwise the with the critical $F=\text{regressionMS}/\text{WithinGroupsMS}$ with a corresponding critical value. Finally, it reports the values of the coefficient of determination r^2 and the standard error of the estimate S_{YX} .

/PAIR

Specifies that the input waves are XY pairs, where each pair must be an X wave followed by a Y wave.

/Q

No results printed in the history area.

/RTO

Reflects the regression through the origin.

/T=*k*

Displays results in a table. *k* specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

/TAIL=*tCode*

Sets the sense of the test when applying Dunnett's test (see /DET). *tCode* is 1 or 2 for a one-tail critical value and 4 for a two-tail critical value.

/TUK

Performs a Tukey-type test on multiple regressions on two or more Y waves. There are two possible Tukey-type tests: The first is performed if the hypothesis of equal slopes is rejected. It compares all combinations of two Y waves to identify if some of the waves have equal slopes. Output is to the M_TukeyMCSlopes wave in the current data folder or optionally to a table. For every Y wave pair, the results include the difference between slopes (absolute value), q, the critical value q_c , and the conclusion set to 1 for accepting the equality of the pair of slopes or 0 for rejecting the hypothesis.

The second Tukey-type test is performed if all the slopes are the same but the elevations are not. The test (see /DET) compares all possible pairs of elevations to determine which satisfy the hypothesis of equality. Output is to the M_TukeyMCElevations wave in the current data folder.

/WSTR=*waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z

Ignores errors.

Details

Inputs may consist of Y waves or XY wave pairs. If X data are not used, the X values are inferred from the Y wave scaling. For multiple waves where only some have pairs, use the /PAIR flag and enter * in each place where the X values should be computed.

For each input StatsLinearRegression calculates:

1. Least squares regression line $y=a+b*x$.
2. Mean value of X: \bar{x} .
3. Mean value of Y: \bar{y} .
4. Sum of the squares $(x_i-\bar{x})^2$.
5. Sum of the squares $(y_i-\bar{y})^2$.

6. Sum of the product ($x_i y_i - xy_{\text{Bar}}$).
7. Standard error of the estimate $S_{YX} =$.
8. F statistic for the hypothesis $\beta = 0$.
9. Critical F value F_c .
10. Coefficient of determination r^2 .
11. Standard error of the regression coefficient S_b .
12. t-statistic for the hypothesis $\beta = \beta_{\text{eta0}}$, NaN if /B is not specified.
13. Critical value t_c for the t-statistic above (used to calculate L1 and L2).
14. Lower confidence interval boundary (L1) for the regression coefficient.
15. Upper confidence interval boundary (L2) for the regression coefficient.

For two Y waves with the same slope, it computes a common slope (bc) and then tests the equality of the elevations (a). In both cases it computes a t-statistic and compares it with a critical value. If the elevations are also the same then it computes the common elevation (ac) and the pooled means of X and Y in (xp) and (yp).

For more than two Y waves it computes:

$$\begin{aligned}
 A_c &= \sum_{j=1}^W A_j; & A_j &= \sum x_i^2 = \sum_{i=0}^{n_j-1} X_i^2 - \frac{1}{n_j} \left(\sum_{i=0}^{n_j-1} X_i \right)^2 \\
 B_c &= \sum_{j=1}^W B_j; & B_j &= \sum xy = \sum_{i=0}^{n_j-1} XY - \frac{1}{n_j} \left(\sum_{i=0}^{n_j-1} X_i \right) \left(\sum_{i=0}^{n_j-1} Y_i \right) \\
 C_c &= \sum_{j=1}^W C_j; & C_j &= \sum y^2 = \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{n_j} \left(\sum_{i=0}^{n_j-1} Y_i \right)^2 \\
 SS_p &= \sum_{j=1}^W C_j - \frac{B_c^2}{A_c} & SS_c &= C_c - \frac{B_c^2}{A_c} & SS_t &= \sum_{j=1}^W \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{N} \left(\sum_{j=1}^W \sum_{i=0}^{n_j-1} Y_i \right)^2 - \frac{\left(\sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i Y_i - \frac{1}{N} \left(\sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i \right) \left(\sum_{j=1}^W \sum_{i=0}^{n_j-1} Y_i \right) \right)^2}{\sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i^2 - \frac{1}{N} \left(\sum_{j=1}^W \sum_{i=0}^{n_j-1} X_i \right)^2} \\
 DF_p &= \sum_{j=1}^W (n_j - 2) & DF_t &= \sum_{j=1}^W n_j - 2
 \end{aligned}$$

where W is the number of Y-waves and $N = \sum_{j=1}^W n_j$ is the total number of data points in all Y-waves.

The test statistic F for equality of slopes is given by: $F = \left(\frac{SS_c - SS_p}{\text{numWaves} - 1} \right) / \frac{SS_p}{DF_p}$

F_c is the corresponding critical value.

Output is to the W_LinearRegressionMC wave in the current data folder.

V_flag will be set to -1 for any error and to zero otherwise.

StatsLogisticCDF

StatsLogisticCDF(x, a, b)

The StatsLogisticCDF function returns the logistic cumulative distribution function

$$F(x, a, b) = \frac{1}{1 + \exp\left(-\frac{x-a}{b}\right)} \text{ where the scale parameter } b > 0 \text{ and the shape parameter is } a.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogisticPDF** and **StatsInvLogisticCDF** functions.

StatsLogisticPDF

StatsLogisticPDF(x, a, b)

The StatsLogisticPDF function returns the logistic probability distribution function

$$f(x, a, b) = \frac{\exp\left(-\frac{x-a}{b}\right)}{b \left[1 + \exp\left(-\frac{x-a}{b}\right)\right]^2} \text{ where the scale parameter } b > 0 \text{ and the shape parameter is } a.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogisticCDF** and **StatsInvLogisticCDF** functions.

StatsLogNormalCDF

StatsLogNormalCDF(x, σ [, θ, α])

The StatsLogNormalCDF function returns the lognormal cumulative distribution function

$$F(x, \sigma, \theta, \mu) = \frac{1}{\sigma\sqrt{2\pi}} \int_{\theta}^x \frac{1}{t-\theta} \exp\left[-\left[\ln\left(\frac{t-\theta}{\mu}\right)\right]^2 / 2\sigma^2\right] dt,$$

for $x \geq \theta$ and $\sigma, \infty > 0$. The standard lognormal distribution is for $\theta=0$ and $\alpha=1$, which are the optional parameter defaults.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalPDF** and **StatsInvLogNormalCDF** functions.

StatsLogNormalPDF

StatsLogNormalPDF(x, σ [, θ, α])

The StatsLogNormalPDF function returns the lognormal probability distribution function

$$f(x, \sigma, \theta, \mu) = \frac{1}{\sigma\sqrt{2\pi}} \frac{1}{x-\theta} \exp\left[-\left[\ln\left(\frac{x-\theta}{\mu}\right)\right]^2 / 2\sigma^2\right]$$

for $x \geq \theta$ and $\sigma, \infty > 0$, where θ is the location parameter, α is the scale parameter and, σ is the shape parameter. The standard lognormal distribution is for $\theta=0$ and $\alpha=1$, which are the optional parameter defaults.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalCDF** and **StatsInvLogNormalCDF** functions.

StatsMaxwellCDF

StatsMaxwellCDF(x, k)

The StatsMaxwellCDF function returns the Maxwell cumulative distribution function

$$F(x; k) = \text{gammp}\left(\frac{3}{2}, \frac{kx^2}{2}\right), \quad x > 0$$

where **gammp** is the regularized incomplete gamma function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellPDF** and **StatsInvMaxwellCDF** functions.

StatsMaxwellPDF

StatsMaxwellPDF(*x*, *k*)

The StatsMaxwellPDF function returns Maxwell's probability distribution function

$$f(x,k) = \sqrt{\frac{2}{\pi}} k^{3/2} x^2 \exp\left(-\frac{kx^2}{2}\right), \quad x \geq 0$$

The Maxwell distribution describes, for example, the speed distribution of molecules in an ideal gas.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellCDF** and **StatsInvMaxwellCDF** functions.

StatsMedian

StatsMedian(*waveName*)

The StatsMedian function returns the median value of a numeric wave *waveName*, which must not contain NaNs.

Example

```
Make/N=5 sample1={1,2,3,4,5}
Print StatsMedian(sample1)
3
Make/N=6 sample2={1,2,3,4,5,6}
Print StatsMedian(sample2)
3.5
```

See Also

Chapter III-12, **Statistics** for a function and operation overview; **WaveStats** and **StatsQuantiles**.

StatsMooreCDF

StatsMooreCDF(*x*, *N*)

The StatsMooreCDF function returns the cumulative distribution function for Moore's R^* , which is used in a nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range $3 \leq N \leq 120$ and does not change appreciably for $N > 120$.

The distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

References

Moore, B.R., A modification of the Rayleigh test for vector data, *Biometrika*, 67, 175-180, 1980.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsCircularMeans** function.

StatsMultiCorrelationTest

StatsMultiCorrelationTest [*flags*] *corrWave*, *sizeWave*

The StatsMultiCorrelationTest operation performs various tests on multiple correlation coefficients. Inputs are two 1D waves: *corrWave*, containing correlation coefficients, and *sizeWave*, containing the size (number of elements) of the corresponding samples. Although you can do all the tests at the same time, it rarely makes sense to do so.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).

/CON={*controlRow*,*tails*}

Performs a multiple comparison test using the *controlRow* element of *corrWave* as a control. It is one- or two-tailed test according to the *tails* parameter. Output is to the M_ControlCorrTestResults wave in the current data folder.

/CONT=cWave

Performs a multiple contrasts test on the correlation coefficients. The contrasts wave, *cWave*, contains the contrast factor, c_i , entry for each of the n correlation coefficients r_i in *corrWave*, and satisfying the condition that the sum of the entries in *cWave* is zero. H_0 corresponds to

$$\sum_{i=0}^{n-1} c_i r_i = 0$$

The test statistic S is

$$S = \left| \sum_{i=0}^{n-1} c_i z_i \right| / \sqrt{\sum_{i=0}^{n-1} c_i^2 / (n_i - 3)}$$

where z_i is the Fisher z transform of the correlation coefficient r_i :

$$z_i = \frac{1}{2} \ln \left(\frac{1 + r_i}{1 - r_i} \right)$$

It produces the SE value, the contrast statistic S , and the critical value, which are labeled ContrastSE, ContrastS, and Contrast_Critical, respectively, in the W_StatsMultiCorrelationTest wave.

/Q

No results printed in the history area.

/T=k

Displays results in a table. k specifies the table behavior when it is closed.

$k=0$: Normal with dialog (default).

$k=1$: Kills with no dialog.

$k=2$: Disables killing.

/TUK

Performs a Tukey-type multi comparison testing between the correlation coefficients by comparing every possible combination of pairs of correlation coefficients, computing the difference in their z-transforms, the SE, and the q statistic:

$$q = \frac{|z_j - z_i|}{\sqrt{2 \left(\frac{1}{n_i - 3} + \frac{1}{n_j - 3} \right)}}$$

The critical value is computed from the q CDF (**StatsInvQCDF**) with degrees of freedom *numWaves* and infinity. Output is to the M_TukeyCorrTestResults wave in the current data folder or optionally to a table.

/Z

Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Without any flags, StatsMultiCorrelationTest computes χ^2 for the correlation coefficients and compares it with the critical value.

$$\chi^2 = \sum_{i=0}^{n-1} z_i^2 (n_i - 3) - \frac{\left(\sum_{i=0}^{n-1} z_i (n_i - 3) \right)^2}{\sum_{i=0}^{n-1} (n_i - 3)}$$

where z_i is the Fisher's z transform of the correlation coefficients and n_i is the corresponding sample size. It computes the common correlation coefficient *rw* and its transform *zw*.

$$z_w = \frac{\sum_{i=0}^{n-1} z_i (n_i - 3)}{\sum_{i=0}^{n-1} (n_i - 3)}$$

These values are calculated even when not appropriate, such as when χ^2 exceeds the critical value and H_0 (all samples came from populations of identical correlation coefficients) is rejected.

The operation also computes ChiSquaredP (due to S.R. Paul), a different variant of χ^2 that is corrected for bias and should be compared with the same critical value. Output is to the W_StatsMultiCorrelationTest wave in the current data folder or optionally to a table.

StatsLinearCorrelationTest, **StatsCircularCorrelationTest**, **StatsDunnettTest**, **StatsTukeyTest**, **StatsInvQCDF**, and **StatsScheffeTest**.

StatsNBinomialCDF

StatsNBinomialCDF(x, k, p)

The StatsNBinomialCDF function returns the negative binomial cumulative distribution function

$F(x, k, p) = \text{Betai}(k, x+1, p)$ where **betai** is the regularized incomplete beta function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialPDF** and **StatsInvNBinomialCDF** functions.

StatsNBinomialPDF

StatsNBinomialPDF(x, k, p)

The StatsNBinomialPDF function returns the negative binomial probability distribution function

$$f(x, k, p) = \binom{x+k-1}{k-1} p^k (1-p)^x, \quad x = 0, 1, 2, \dots$$

where $\binom{a}{b}$ is the **binomial** function.

The binomial distribution expresses the probability of the k th success in the $x+k$ trial for two mutually exclusive results (success and failure) and p the probability of success in a single trial.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialCDF** and **StatsInvNBinomialCDF** functions.

StatsNCChiCDF

StatsNCChiCDF(x, n, d)

The StatsNCChiCDF function returns the noncentral chi-squared cumulative distribution function

$$F(x, n, d) = \sum_{i=0}^{\infty} \exp(-d/2) \frac{(d/2)^i}{i!} F_c(x, n+2i)$$

where $n > 0$ corresponds to degrees of freedom, $d \geq 0$ is the noncentrality parameter, and F_c is the central chi-squared distribution.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentPDF**, **StatsStudentCDF**, and **StatsNCTCDF** functions.

StatsNormalCDF

StatsNormalCDF(x, m, s)

The StatsNormalCDF function returns the normal cumulative distribution function

$$F(x, \mu, \sigma) = \frac{1}{2} + \frac{1}{2} \operatorname{erf}\left(\frac{x - \mu}{\sigma \sqrt{2}}\right) \text{ where } \operatorname{erf} \text{ is the error function.}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalPDF** and **StatsInvNormalCDF** functions.

StatsNormalPDF

StatsNormalPDF(x, m, s)

The StatsNormalPDF function returns the normal probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right)$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalCDF** and **StatsInvNormalCDF** functions.

StatsNPMCTest

StatsNPMCTest [flags] [wave1, wave2,... wave100]

The StatsNPMCTest operation performs a number of nonparametric multiple comparison tests. Output waves are saved in the current data folder according to the test(s) performed. Some tests are only appropriate when you have the same number of samples in all groups. StatsNPMCTest usually follows **StatsANOVA1Test** or **StatsKWTest**.

Flags

/ALPH = val Sets the significance level (default val=0.05).

/CIDX=controlIndex Performs nonparametric multiple comparisons on a control group specified by the zero-based controlIndex wave in the input list. Output is to the M_NPCCResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the rank sums of the control and each of the other waves; the second contains the standard error (SE); the third contains the statistic q, defined as the ratio of the difference in rank sums to SE; the fourth contains the critical value which also depends on the tails specification (see /TAIL); and the fifth contains the conclusion with 0 to reject H₀ and 1 to accept it. One version of this test applies when all inputs contain the same number of samples. When that is not the case, it uses the Dunn-Hollander-Wolfe approach to compute an appropriate SE and to handle possible ties.

/CONW=cWave Performs a nonparametric multiple contrasts tests. cWave has one point for each input wave. The cWave value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If $cWave=\{0,1,1,1,2\}$, then the contrast is computed as

$$\text{contrast: } \frac{1}{3}[R_{c1}+R_{c2}+R_{c3}]-R_{c4}$$

where R_{ni} is the normalized rank sum of the samples from the corresponding input wave. Note the significance of allowing zeros in the contrast wave because the actual ranking is performed on the pool of all the samples.

Output is to the M_NPMConResults wave in the current data folder or optionally to a table. The output column contents are: the first is the contrast value; the second is the standard error (SE); the third is the statistic S, which is the ratio of the absolute value of the contrast to SE; the fourth is the critical value (from χ^2 the approximation); and the fifth is the conclusion with 0 to reject H_0 and 1 indicating acceptance.

This test supports input waves with different number of samples and can also handle tied ranks. Note that the contrast wave used here is structured differently than for **StatsMultiCorrelationTest**.

/DHW

Performs the Dunn-Holland-Wolfe test, which supports unequal number of samples and accounts for ties in the rank sums. Output is to the M_NPMCDHWResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the means of the rank sums (rank sums divided by the number of samples in the group), the second contains the standard error (SE), the third contains the DHW statistic Q, the fourth contains the critical value, and the fifth contains the conclusion (0 to reject H_0 and 1 to accept).

/Q

No results printed in the history area.

/SWN

Creates a text wave, T_NPCCRResultsDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.

/T=k

Displays results in a table. k specifies the table behavior when it is closed.

$k=0$: Normal with dialog (default).

$k=1$: Kills with no dialog.

$k=2$: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.

/TAIL=tc

Specifies H_0 with /CIDX.

$tc=1$: One tailed test ($\alpha_c \leq \alpha_a$).

$tc=2$: One tailed test ($\alpha_c \geq \alpha_a$).

$tc=4$: Default; two tailed test ($\alpha_c = \alpha_a$).

Code combinations are not allowed.

/SNK

Performs a nonparametric variation on the Student-Newman-Keuls test where the standard error SE is a function of p (the rank difference). This test requires equal numbers of samples in all groups; use /DHW for unequal sizes.

Output is to the M_NPMCSNKResults wave in the current data folder. The output column contents are: the first contains the difference between rank sums, the second contains the standard error (SE), the third contains the p value (rank difference), the fourth the statistic, the fifth contains the critical value, and the sixth contains the conclusion (0 to reject H_0 and 1 to accept). This test is more sensitive to differences than the Tukey test (/TUK).

/TUK

Perform a Tukey-type (Nemenyi) multiple comparison test using the difference between the rank sums. This is the default that is performed if you do not specify any of the test flags. This test requires equal numbers of points in all waves; use /DHW for unequal sizes.

Output is to the M_NPMCTukeyResults wave in the current data folder. The output column contents are: the first contains the difference between the rank sums, the second contains the SE values, the third contains the statistic q , the fourth contains the critical value for this specific alpha and the number of groups; and the last contains a

conclusion flag with 0 indicating a rejection of H_0 and 1 indicating acceptance. H_0 postulates that the paired means are the same.

/WSTR=*waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z

Ignores errors.

Details

Inputs to StatsNPMCTest are two or more 1D numerical waves (one wave for each group of samples) containing two or more valid entries. The waves must have the same number of points for the use /SNK and /TUK tests, otherwise, for waves of differing lengths you must use the Dunn-Hollander-Wolfe test (/DHW).

V_flag will be set to zero for no execution errors. Individual tests may fail if, for example, there are different number of samples in the input waves for a test that requires an equal number of points. StatsNPMCTest skips failed tests and V_flag will be a binary combination identifying the failed test(s):

V_flag & 1 Tukey method failed (/TUK).

V_flag & 2 Student-Newman-Keuls failed (/SNK).

V_flag will be set to -1 for any other errors.

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test** and **StatsKWTest**.

For multiple comparisons in parametric tests see: **StatsDunnettTest** and **StatsScheffeTest**.

StatsNPNominalSRTest

StatsNPNominalSRTest [*flags*] [*srcWave*]

The StatsNPNominalSRTest operation performs a nonparametric serial randomness test for nominal data consisting of two types. The null hypothesis is that the data are randomly distributed. Output is to the W_StatsNPSRTest wave in the current data folder.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).

/Q No results printed in the history area.

/P={*m,n,u*} Provides a summary of the data instead of providing the nominal series. *m* is the number of elements of the first type, *n* is the number of elements of the second type, and *u* is the number of runs or contiguous sequences of each type. Do not use *srcWave* with /P.

/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

/Z Ignores errors.

Details

The input wave to StatsNPNominalSRTest is specified with *srcWave* or /P. The wave must contain exactly two values. If *srcWave* is a text wave, then each type can be designated by a letter or by a short string (less than 200 characters). If *srcWave* is numeric, you should avoid the usual floating point waves, which can give rise to internal representations of more than two distinct values. Output to W_StatsNPSRTest includes the total number of points (*N*), the number of occurrences (*m*) of the first variable, the number of occurrences (*n*) of the second variable, and the number of runs (*u*). When both *m* and *n* are less than 300, it computes the P value (probability $P(u' < u)$) and the critical values using the Swed and Eisenhart algorithm. When *m* or *n* are larger than 300, it computes the mean and standard deviation of an equivalent normal distribution with the corresponding critical value.

StatsParetoCDF

StatsParetoCDF(*x*, *a*, *c*)

The StatsParetoCDF function returns the Pareto cumulative distribution function $F(x; a, c) = 1 - \left(\frac{a}{x}\right)^c$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoPDF** and **StatsInvParetoCDF** functions.

StatsParetoPDF

StatsParetoPDF(*x*, *a*, *c*)

The StatsParetoPDF function returns the Pareto probability distribution function

$$f(x; a, c) = \frac{c}{x} \left(\frac{a}{x}\right)^c, \quad \begin{matrix} a, c > 0 \\ x \geq a \end{matrix}$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoCDF** and **StatsInvParetoCDF** functions.

StatsPermute

StatsPermute(*waveA*, *waveB*, *dir*)

The StatsPermute function permutes elements in *waveA* based on the lexicographic order of *waveB* and the direction *dir*. It returns 1 if a permutation is possible and returns 0 otherwise. Use *dir*=1 for the next permutation and *dir*=-1 for a previous permutation.

Details

Both *waveA* and *waveB* must be numeric. The lexicographic order of elements in the index wave is set so that permutations start with the index wave *waveB* in ascending order and end in descending order. Elements of *waveA* are permuted in place according to the order of the indices in *waveB* which are clipped (after permutation) to the valid range of entries in *waveA*. *waveB* is also permuted in place in order to allow you to obtain sequential permutations. If *waveA* consists of real numbers you can permute them using the lexicographic value of the entries directly. To do so pass "" for *waveB*. Whenever it returns 0, neither *waveA* and *waveB* are changed.

Examples

```
Function allPermutations(num)
    Variable num
    Variable i,nf=factorial(num)
    Make/O/N=(num) wave0=p+1,waveA,waveB=p
    Print wave0
    for(i=0;i<nf;i+=1)
        waveA=wave0
        if(statsPermute(waveA,waveB,1)==0)
            break
        endif
        print waveA
    endfor
end
```

Executing allPermutations(3) prints:

```
wave0[0]= {1,2,3}
waveA[0]= {1,3,2}
waveA[0]= {2,1,3}
waveA[0]= {2,3,1}
waveA[0]= {3,1,2}
waveA[0]= {3,2,1}
```

See Also

Chapter III-12, **Statistics** for a function and operation overview.

StatsPoissonCDF

StatsPoissonCDF(*x*, *λ*)

The StatsPoissonCDF function returns the Poisson cumulative distribution function

$$F(x, \lambda) = \sum_{i=0}^x \frac{\exp(-\lambda) \lambda^i}{i!}, \quad x = 0, 1, 2, \dots$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonPDF** and **StatsInvPoissonCDF** functions.

StatsPoissonPDF

StatsPoissonPDF(*x*, *λ*)

The StatsPoissonPDF function returns the Poisson probability distribution function

$$f(x, \lambda) = \frac{\exp(-\lambda) \lambda^x}{x!}, \quad x = 0, 1, 2, \dots$$

where λ is the shape parameter.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonCDF** and **StatsInvPoissonCDF** functions.

StatsPowerCDF

StatsPowerCDF(*x*, *b*, *c*)

The StatsPowerCDF function returns the Power Function cumulative distribution function

$$F(x; b, c) = \left(\frac{x}{b}\right)^c \text{ where the scale parameter } b, c > 0 \text{ and } b \geq x \geq 0.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerPDF** and **StatsInvPowerCDF** functions.

StatsPowerNoise

StatsPowerNoise(*b*, *c*)

The StatsPowerNoise function returns a pseudorandom value from the power distribution function with probability distribution:

$$f(x, b, c) = \frac{c}{x} \left(\frac{x}{b}\right)^c$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **SetRandomSeed**, **StatsPowerPDF**, **StatsInvPowerCDF**, and **StatsInvPowerCDF** functions.

StatsPowerPDF

StatsPowerPDF(*x*, *b*, *c*)

The StatsPowerPDF function returns the Power Function probability distribution function

$$F(x; b, c) = \left(\frac{x}{b}\right)^c \text{ where the scale parameter } b, c > 0 \text{ and } b \geq x \geq 0.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerCDF** and **StatsInvPowerCDF** functions.

StatsQCDF

StatsQCDF(*q*, *r*, *c*, *df*)

The StatsQCDF function returns the value of the Q cumulative distribution function for *r* the number of groups, *c* the number of treatments, and *df* the error degrees of freedom ($f=rc(n-1)$ with sample size *n*).

Details

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use $r=1$.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTukeyTest** function.

StatsQuantiles

StatsQuantiles [*flags*] *srcWave*

The StatsQuantiles operation computes quantiles and elementary univariate statistics for a set of data in *srcWave*.

Flags

/ALL	Invokes all flags except /Q, /QM, and /Z.
/BOX	Computes parameters necessary to construct a box plot.
/iNaN	Ignores NaNs, which are sorted to the end of the array by default.
/IW	Creates an index wave W_QuantilesIndex. W_QuantilesIndex[i] corresponds to the position of <i>srcWave</i> [i] when sorted from minimum to maximum.
/Q	No information printed in the history area.
/QM= <i>qMethod</i>	Specifies the method for computing quartiles. <i>qMethod</i> has one of these values: 0: Tukey (default). 1: Minitab. 2: Moore and McCabe. 3: Mendenhall and Sincich. See Details for more information.
/QW	Creates a single precision wave W_QuantileValues containing the quantile value corresponding to each entry in <i>srcWave</i> .
/STBL	Uses a stable sort, which may require significant computation time for multiple entries with the same value.
/TM	Computes the tri-mean: $0.25*(V_Q25+2*median+V_Q75)$.
/TRIM= <i>tVal</i>	Computes the trimmed mean which is the mean value of the entries between the quantiles <i>tVal</i> (in %) and 100- <i>tVal</i> . By default <i>tVal</i> =25 and the trimmed mean corresponds to the midmean.
/Z	Ignores any errors.

Details

StatsQuantiles produces quick five-number summaries or more detailed results for univariate data. Values are returned in the wave W_StatsQuantiles and in the variables:

V_min	Minimum value.
V_max	Maximum value.
V_Median	Median value.
V_Q25	Lower quartile.
V_Q75	Upper quartile.

V_IQR Inter-quartile range V_Q75-VQ25, which is also known as the H-spread.

Entries in the wave W_StatsQuantiles depend on your choice of flags. Each row has a row label explicitly defining its value. If you use the /ALL flag, W_StatsQuantiles will contain the following row labels:

minValue	lowerInnerFence
maxValue	lowerOuterFence
Median	upperInnerFence
Q25	upperOuterFence
Q75	triMean
IQR	trimmedMean

Otherwise, W_StatsQuantiles will contain the first five entries and any additionally requested value. You should always access values using the dimension labels (see **Dimension Labels** on page II-93).

There is frequently some confusion in comparing statistical results computed by different programs because each may use a different definition of quartiles. You can specify the method of computing the quartiles as you prefer with the /QM flag. If you neglect to choose a method, StatsQuantiles uses Tukey's method, which computes quartiles (also called hinges) as the lower and upper median values between the median of the data and the edges of the array. The Moore and McCabe method is similar to Tukey's method except you do not include the median itself in computing the quartiles. Mendenhall and Sincich compute the quartiles using $1/4$ and $3/4$ of (numDataPoints+1) and round to the nearest integer (if the fraction part is exactly 0.5 they round up for the lower quartile and down for the upper quartile). Minitab uses the same expressions but instead of rounding it uses linear interpolation.

StatsQuantiles uses a stable index sorting routine so that

```
IndexSort W_QuantilesIndex,srcWave
```

is a monotonically increasing wave.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **WaveStats**, **StatsMedian**, **Sort**, and **MakeIndex**.

StatsRankCorrelationTest

StatsRankCorrelationTest [*flags*] *waveA*, *waveB*

The StatsRankCorrelationTest operation performs Spearman's rank correlation test on *waveA* and *waveB*, 1D waves containing the same number of points. Output is to the W_StatsRankCorrelationTest wave in the current data folder.

Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores errors.

Details

StatsRankCorrelationTest ranks *waveA* and *waveB* and then computes the sum of the squared differences of ranks for all rows. Ties are assigned an average rank and the corrected Spearman rank correlation coefficient is computed with ties. It reports the sum of the squared ranks (sumDi2), the sums of the ties

StatsRayleighCDF

coefficients (sumTx and sumTy respectively), the Spearman rank correlation coefficient (in the range [-1,1]), and the critical value. H_0 corresponds to zero correlation against the alternative of nonzero correlation. The critical value is usually lower than the one in published tables. When the first derivative of the CDF is discontinuous, tables tend to use a more conservative value by choosing the next transition of the CDF as the critical value. StatsRankCorrelationTest is not as powerful as **StatsLinearCorrelationTest**.

See Also

Chapter III-12, **Statistics** for a function and operation overview.

StatsLinearCorrelationTest, **StatsCircularCorrelationTest**, **StatsKendallTauTest**, **StatsSpearmanRhoCDF**, and **StatsInvSpearmanCDF**.

StatsRayleighCDF

StatsRayleighCDF(x [, s [, m]])

The StatsRayleighCDF function returns the Rayleigh cumulative distribution function

$F(x; \sigma, \mu) = 1 - \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$ with defaults $s=1$ and $m=0$. It returns NaN for $s \leq 0$ and zero for $x \leq m$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighPDF** and **StatsInvRayleighCdf** functions.

StatsRayleighPDF

StatsRayleighPDF(x [, s [, m]])

The StatsRayleighPDF function returns the Rayleigh probability distribution function

$f(x; \sigma, \mu) = \frac{x-\mu}{\sigma^2} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$ with defaults $s=1$ and $m=0$. It returns NaN for $s \leq 0$ and zero for $x \leq m$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighCDF** and **StatsInvRayleighCdf** functions.

StatsRectangularCDF

StatsRectangularCDF(x, a, b)

The StatsRectangularCDF function returns the rectangular (uniform) cumulative distribution function

$$F(x, a, b) = \begin{cases} 0 & x \leq a \\ \frac{x-a}{b-a} & a \leq x \leq b \\ 1 & x \geq b \end{cases} \quad \text{where } a < b.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularPDF** and **StatsInvRectangularCDF** functions.

StatsRectangularPDF

StatsRectangularPDF(x, a, b)

The StatsRectangularPDF function returns the rectangular (uniform) probability distribution function

$$f(x, a, b) = \begin{cases} \frac{1}{b-a} & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases}$$

where $a < b$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularCDF** and **StatsInvRectangularCDF** functions.

StatsResample

StatsResample [*flags*] *srcWave*

The StatsResample operation resamples *srcWave* by drawing (with replacement) /N=*numPoints* values from *srcWave* and storing them in the wave W_Resampled. You can iterate the process and compute various statistics on the data samples.

Flags

/ITER= <i>n</i>	Repeats the resampling for <i>n</i> iterations, which is useful only when combined with /WS or /SQ.
/K	Kills W_Resampled after passing it to WaveStats. When /ITER is used, W_Resampled is not saved.
/N= <i>numPoints</i>	Specifies the number of points sampled from <i>srcWave</i> .
/Q	No information printed in the history area.
/SQ= <i>m</i>	Uses StatsQuantiles to compute the data quartiles. The methods are: <i>m</i> =0: Tukey (default). <i>m</i> =1: Minitab. <i>m</i> =2: Moore and McCabe. <i>m</i> =3: Mendenhall and Sincich. See Details for information about how the results are stored. The default trim value is 25%.
/WS= <i>m</i>	Uses WaveStats operation to calculate data statistics. <i>m</i> =0: Creates a new wave containing the samples (default). <i>m</i> =1: Creates the new wave and passes it to WaveStats/Q/M=1. <i>m</i> =1: Creates the new wave and passes it to WaveStats/Q/M=2. See Details for information about how the results are stored.
/Z	Ignores any errors.

Details

StatsResample can perform Bootstrap Analysis, permutations tests, and Monte-Carlo simulations. It draws the specified number of data points (with replacement) from *srcWave* and places them in a destination wave W_Resampled.

Specify /WS or /SQ to use the WaveStats or StatsQuantiles operations, respectively, to compute results directly from the data. StatsResample normally creates the wave W_Resampled and, optionally, the M_WaveStats and W_StatsQuantiles waves. Both options also create various V_ variables. If you use more than one iteration, StatsResample creates instead the waves M_WaveStatsSamples and M_StatsQuantilesSamples for the results.

M_WaveStatsSamples (with /WS) contains a column for each iteration. Each column is equivalent to the contents of M_WaveStats for that iteration. You can use the command

```
Edit M_WaveStatsSamples.ld
```

to display the results in a table using row labels, and, for example, to display a graph of the rms of the samples as a function of iteration number execute:

```
Display M_WaveStatsSamples[5][ ]
```

M_StatsQuantilesSamples (with /SQ) contains a column for each iteration. Each column consists of the contents of W_StatsQuantiles for the corresponding data. Here again you can execute the command

```
Edit M_StatsQuantilesSamples.ld
```

to display the wave in a table using row labels. To display a graph of the median as a function of iteration execute:

```
Display M_statsQuantilesSamples[2][ ]
```

Note: Both WaveStats and StatsQuantiles create V_ variables. Some are used by both operations. These variables are valid only if you use either /SQ or /WS, but not both, and only if you are not using /ITER.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **WaveStats** and **StatsQuantiles**.

StatsRunsCDF

StatsRunsCDF(*n*, *r*)

The StatsRunsCDF function returns the cumulative distribution function for the up and down runs distribution for total number of runs *r* in a random linear arrangement of *n* unequal elements. There is no closed form expression. It is computed numerically from the recursion of the probability density

$$f(r, n) = \frac{rf(r, n-1) + 2f(r-1, n-1) + (n-r)f(r-2, n-1)}{n} \text{ with the initial condition } f(1, n) = \frac{2}{n!}.$$

Olmstead, P.S., Distribution of sample arrangements for runs up and down, *Annals of Mathematical Statistics*, 17, 24-33, 1946.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsSRTTest** function.

StatsScheffeTest

StatsScheffeTest [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsScheffeTest operation performs Scheffe's test for the equality of the means. It supports two basic modes: the default tests all possible combinations of pairs of waves; the second tests a single combination where the precise form of H_0 is determined by the coefficients of a contrast wave (see /CONT). Output is to the M_ScheffeTestResults wave in the current data folder.

Flags

/ALPH=*val* Sets the significance level (default 0.05).

/CONW=*cWave* Performs a multiple contrasts test. *cWave* has one point for each input wave. The *cWave* value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If *cWave*={0,1,1,1,2}, then the contrast hypothesis H_0 corresponds to:

$$\frac{\bar{X}_1 + \bar{X}_2 + \bar{X}_3}{3} - \bar{X}_4 = 0$$

For each pair of waves (*i*, *j*) with $i \neq j$, it computes

$$SE_{ij} = \sqrt{s^2 \left(\frac{1}{n_j} + \frac{1}{n_i} \right)}, \quad s^2 = \sum_{i=1}^W \sum_{j=0}^{n_i-1} X_j^2 - \sum_{i=1}^W \frac{\left(\sum_{j=0}^{n_i-1} X_j \right)^2}{n_i}$$

the statistic

$$S = \frac{\left| \sum_{i=0}^{n-1} c_i \bar{X}_i \right|}{SE}$$

the critical value, and a result field which is set to 1 if H_0 should be accepted or 0 if it should be rejected. *W* is the total number of waves, n_i and \bar{X}_i are respectively the number of data points and the average of wave *i*.

/Q No results printed in the history area.

/SWN Creates a text wave, T_ScheffeDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.

/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.
 The table is associated with the test, not the data. If you repeat the test, it will update
 any existing table with the new results.

/WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample
 data. Use *waveListString* instead of listing each wave after the flags.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The default of StatsScheffeTest (also known as the S test) tests the hypotheses of equality of means for each possible pair of samples. It is not as powerful as Tukey's test (**StatsTukeyTest**) and is more useful for hypotheses formulated as multiple contrasts (see /CONT).

StatsSignTest

StatsSignTest [*flags*] *wave1*, *wave2*

The StatsSignTest operation performs the sign test for paired-sample data contained in *wave1* and *wave2*.

Flags

/ALPH=*val* Sets the significance level (default 0.05).
 /Q No results printed in the history area.
 /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.
 /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The input waves must be the equal length, real numeric waves and must not contain any NaNs or INFs. Results are saved in the wave W_SignTest and are optionally displayed in a table. StatsSignTest computes the differences in each pair and counts the total number of entries with positive and negative differences, and tests the results using a binomial distribution. When the number of data pairs exceeds 1024 it uses a normal approximation to the binomials for calculating the probabilities and the power of the test.

StatsSpearmanRhoCDF

StatsSpearmanRhoCDF(*r*, *N*)

The StatsSpearmanRhoCDF function returns the cumulative distribution function for Spearman's *r*, which is used in rank correlation test. It is valid for $N > 1$ and $-1 \leq r \leq 1$. The distribution is mostly computed using the Edgeworth series expansion.

StatsSRTest

StatsSRTest [*flags*] *srcWave*

The StatsSRTest operation performs a parametric or nonparametric serial randomness test on *srcWave*, which must contain finite numerical data. The null hypothesis of the test is that the data are randomly distributed. Output is to the W_StatsSRTest wave in the current data folder.

Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/GCD	Tests the output of a random number generator (RNG). <i>srcWave</i> consists of values between 0 and 2^{32} (converted to unsigned 32-bit integers). GCD computes the gcd for consecutive pairs of data in <i>srcWave</i> . The number of steps in the GCD and the distribution of the GCD's are compared with ideal distributions and corresponding P values are reported. This test is part of Marsaglia's Die-Hard battery of tests. P-values close to either 0 or 1 indicate a nonideal RNG. You should use the reported minimum and maximum values to check that the input is indeed in the proper range. Typically <i>srcWave</i> consists of at least $1e6$ entries.
/NP	Performs a nonparametric serial randomness test by counting the numbers of runs up and down and computing the probability that such a value is obtained by chance.
/P	Performs a parametric serial randomness test.
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/Z	Ignores errors.

Details

The parametric test for serial randomness is according to Young. C is given by

$$C = 1 - \frac{\sum_{i=0}^{n-2} (X_i - X_{i+1})^2}{2 \sum_{i=0}^{n-1} (X_i - \bar{X})^2}$$

where \bar{X} is the mean and *n* is the number of points in *srcWave*. The critical value is obtained from mean square successive difference distribution **StatsInvCMSSDCDF**. For more than 150 points, StatsSRTest uses the normal approximation and provides the critical values from the normal distribution. For samples from a normal distribution, C is symmetrically distributed about 0 with positive values indicating positive correlation between successive entries and negative values corresponding to negative correlation.

The nonparametric test consists of counting the number of runs that are successive positive or successive negative differences between sequential data. If two sequential data are the same it computes two numbers of runs by considering the two possibilities where the equality is replaced with either a positive or a negative difference. The results of the operation include the number of runs up and down, the number of unchanged values (the number of places with no difference between consecutive entries), the size of the longest run and its associated probability, the number of converted equalities, and the probability that the number of runs is less than or equal to the reported number (**StatsRunsCDF**). When equalities are encountered the operation computes the probabilities that the computed number of runs or less can be found in an equivalent random sequence.

Converted equalities are those with the same sign on both sides so that when we replace the equality by the opposite sign we increase the number of runs. The equalities that are not converted are found between two

different signs and therefore regardless of the sign that we give them they do not affect the total number of runs. We implicitly assume that the data does not contain more than one sequential equalities.

The longest run is determined without taking into account equalities or their conversions. The probability of the longest run is computed from Equation 6 of Olmstead, which is accurate within 0.001 when the number of runs is 5 or more. This probability applies to either positive or negative differences and should be divided by two if a specific sign is selected.

StatsStudentCDF

StatsStudentCDF(*t*, *n*)

The StatsStudentCDF function returns the Student (uniform) cumulative distribution function

$$F(t, n) = \begin{cases} \frac{1}{2} \left\{ 1 + I \left(\frac{n}{2}, \frac{1}{2}; 1 \right) - I \left(\frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) \right\} & t > 0 \\ \frac{1}{2} \left\{ 1 + I \left(\frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) - I \left(\frac{n}{2}, \frac{1}{2}; 1 \right) \right\} & t < 0 \\ \frac{1}{2} & t = 0 \end{cases}$$

where $n > 0$ is degrees of freedom and is the incomplete beta function **betai**.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentPDF** and **StatsInvStudentCDF** functions.

StatsStudentPDF

StatsStudentPDF(*t*, *n*)

The StatsStudentPDF function returns the Student (uniform) probability distribution function

$$f(t, n) = \frac{\left(\frac{n}{n+t^2} \right)^{(n+1)/2}}{\sqrt{n} B \left(\frac{n}{2}, \frac{1}{2} \right)}$$

where $n > 0$ is degrees of freedom and $B()$ is the **beta** function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentCDF** and **StatsInvStudentCDF** functions.

StatsTopDownCDF

StatsTopDownCDF(r, N)

The StatsTopDownCDF function returns the cumulative distribution function for the top-down correlation coefficient. It is computationally intensive because it must evaluate many permutations [$O((n!)^2)$]. It exactly calculates the distribution for $3 \leq N \leq 7$; outside this range it uses Monte-Carlo estimation for $8 \leq N \leq 50$ and asymptotic Normal approximation for $N > 50$. The Monte-Carlo estimate uses 1e6 random permutations fitted with two 9-order polynomials for the range [-1,0] and [0,1]. The results are within 0.2% of exact values where known.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest** and **StatsInvTopDownCDF** functions.

StatsTriangularCDF

StatsTriangularCDF(x, a, b, c)

The StatsTriangularCDF function returns the triangular cumulative distribution function

$$F(x, a, b, c) = \begin{cases} \frac{(x-a)^2}{(b-a)(c-a)} & a \leq x \leq c \\ 1 - \frac{(b-x)^2}{(b-a)(c-a)} & c \leq x \leq b \end{cases}$$

where $a < c < b$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularPDF** and **StatsInvTriangularCDF** functions.

StatsTriangularPDF

StatsTriangularPDF(x, a, b, c)

The StatsTriangularPDF function returns the triangular probability distribution function

$$f(x, a, b, c) = \begin{cases} \frac{2(x-a)}{(b-a)(c-a)} & a \leq x \leq c \\ \frac{2(b-x)}{(b-a)(c-a)} & c < x < b \\ 0 & \text{otherwise.} \end{cases}$$

where $a < c < b$.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularCDF** and **StatsInvTriangularCDF** functions.

StatsTrimmedMean

StatsTrimmedMean(waveName, trimValue)

The StatsTrimmedMean function returns the mean of the wave *waveName* after removing *trimValue* fraction of the values from both tails of the distribution. *trimValue* is a number in the range [0, 0.5]. *waveName* can be any real numeric type.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsQuantiles** and **mean**.

StatsTTest

StatsTTest [*flags*] *wave1* [, *wave2*]

The StatsTTest operation performs two kinds of T-tests: the first compares the mean of a distribution with a specified mean value (/MEAN) and the second compares the means of the two distributions contained in *wave1* and *wave2*, which must contain at least two data points, can be any real numeric type, and can have an arbitrary number of dimensions. Output is to the W_StatsTTest wave in the current data folder or optionally to a table.

Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /CI Computes the confidence intervals for the mean(s).
- /DFM=*m* Specifies method for calculating the degrees of freedom.
 m=0: Default; computes equivalent degrees of freedom accounting for possibly different variances.
 m=1: Computes equivalent degrees of freedom but truncates to a smaller integer.
 m=2: Computes degrees of freedom by $DF=n_1+n_2-2$, where *n* is the sum of points in the wave. Appropriate when variances are equal.
- /MEAN=*meanV* Compares *meanV* with the mean of the distribution in *wave1*. Outputs are the number of points in the wave, the degrees of freedom (accounting for any NaNs), the average, standard deviation (*σ*),

$$s_{\bar{x}} = \frac{\sigma}{\sqrt{DF+1}} \text{ the statistic } t = \frac{\bar{X} - \text{meanV}}{s_{\bar{x}}}$$
 and the critical value, which depends on /TAIL.
- /PAIR Specifies that the input waves are pairs and computes the difference of each pair of data to get the average difference \bar{d} and the standard error of the difference $S_{\bar{d}}$. The t statistic is the ratio of the two

$$t = \frac{\bar{d}}{S_{\bar{d}}}$$
 In this case H_0 is that the difference \bar{d} is zero.
 This mode does not support /CI and /DFM.
- /Q No results printed in the history area.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.
 The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /TAIL=*tc* Specifies H_0 for /CIDX.
 tc=1: One tailed test ($\alpha_1 \leq \alpha_2$).
 tc=2: One tailed test ($\alpha_1 \geq \alpha_2$).
 tc=4: Default; two tailed test ($\alpha_1 \neq \alpha_2$).
- /Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (*wave1*). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).

When comparing the means of two distributions, the t statistic is given by

$$t = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{s_1^2}{n_1 - 1} + \frac{s_2^2}{n_2 - 1}}} \text{ where } s_i^2 \text{ are variances, } n_i \text{ the number of samples, and } \bar{X}_i \text{ the averages of the waves.}$$

StatsTukeyTest

The different test are:

H_0	Rejection Condition
$\alpha_1 = \alpha_2$	$ t \geq Tc(\alpha, v)$
$\alpha_1 > \alpha_2$	$t \leq Tc(\alpha, v)$
$\alpha_1 < \alpha_2$	$t \geq Tc(\alpha, v)$

Tc is the critical value and v is the effective number of degrees of freedom, which accounts for possibly unequal variances:

$$v = \frac{\left(\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right)^2}{\frac{\left(\frac{s_1^2}{n_1} \right)^2}{n_1 - 1} + \frac{\left(\frac{s_2^2}{n_2} \right)^2}{n_2 - 1}}$$

The critical values (Tc) are computed by numerically by solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x) = \begin{cases} \frac{1}{2} \text{betai}\left(\frac{v}{2}, \frac{1}{2}, \frac{v}{v+x^2}\right) & x < 0 \\ 1 - \frac{1}{2} \text{betai}\left(\frac{v}{2}, \frac{1}{2}, \frac{v}{v+x^2}\right) & x \geq 0 \end{cases}$$

To get the critical value for the upper one-tail test we solve $F(x)=1-\alpha$. For the lower one-tail test we solve for x the equation $F(x)=\alpha$. In the two-tailed test the lower critical value is a solution for $F(x)=\alpha/2$ and the upper critical value is a solution for $F(x)=1-\alpha/2$.

The T-test assumes both samples are randomly taken from normal population distributions.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsStudentCDF**, **StatsStudentPDF**, and **StatsInvStudentCDF**.

StatsTukeyTest

StatsTukeyTest [*flags*] [*wave1, wave2,... wave100*]

The StatsTukeyTest operation performs multiple comparison Tukey (HSD) test and optionally the Newman-Keuls test. Output is to the M_TukeyTestResults wave in the current data folder. StatsTukeyTest usually follows **StatsANOVA1Test**.

Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/NK	Computes the Newman-Keuls test.
/Q	No results printed in the history area.
/SWN	Creates a text wave, T_TukeyDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing.
/WSTR= <i>waveListString</i>	Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.
/Z	Ignores errors.

Details

Inputs to StatsTukeyTest are two or more 1D numeric waves (one wave for each group of samples) containing any numbers of points but with at least two or more valid entries.

The contents of the M_TukeyTestResults columns are: the first contains the difference between the group means $\bar{X}_i - \bar{X}_j$, the second contains SE (supports unequal number of points), the third contains the q statistic for the pair, and the fourth contains the critical q value, the fifth contains the conclusion with 0 to reject H_0 ($\alpha_i = \alpha_j$) or 1 to accept H_0 , with /NK, the sixth contains the p values

$$p = \text{rank}[\bar{X}_i] - \text{rank}[\bar{X}_j] + 1$$

the seventh contains the critical values, and the eighth contains the Newman-Keuls conclusion (with 0 to reject and 1 to accept H_0). The order of the rows is such that all possible comparisons are computed sequentially starting with the comparison of the group having the largest mean with the group having the smallest mean.

V_flag will be set to -1 for any error and to zero otherwise.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test**, **StatsScheffeTest**, and **StatsDunnnettTest**.

StatsUSquaredCDF**StatsUSquaredCDF(u2, n, m, method, useTable)**

The StatsUSquaredCDF function returns the cumulative distribution function for Watson's U^2 with parameters $u2$ (U^2 statistic) and integer sample sizes n and m . The calculation is computationally intensive, on the order of $\text{binomial}(n+m, m)$. Use a nonzero value for *useTable* to search a built-in table of values. If n and m cannot be found in the table, it will proceed according to *method*:

<i>method</i>	What It Does
0	Exact computation using Burr algorithm (could be slow).
1	Tiku approximation using chi-squared.
2	Use built-in table only and return a NaN if not in table.

For large n and m , consider using the Tiku approximation. To abort execution, press Command-period (Macintosh) or Ctrl+Break (Windows).

Precomputed tables, using the algorithm described by Burr, contain these values:

<i>n</i>	<i>m</i>
4	4-30
5	5-30
6	6-30
7	7-30
8	8-26
9	9-22
10	10-18
11	11-16
12	12-14
13	13

StatsVariancesTest

Because n and m are interchangeable, n should always be the smaller value. For $n > 8$ the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with m values exceeding these limits.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWatsonUSquaredTest** and **StatsInvUSquaredCDF** functions.

StatsVariancesTest

StatsVariancesTest [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsVariancesTest operation performs Bartlett's or Levene's test to determine if wave variances are equal. Output is to the W_StatsVariancesTest wave in the current data folder or optionally to a table.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).
/METH=*m* Specifies the test type.
 $m=0$: Bartlett test (default).
 $m=1$: Levene's test using the mean.
 $m=2$: Modified Levene's test using the median.
 $m=3$: Modified Levene's test using the 10% trimmed mean.
/Q No results printed in the history area.
/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 $k=0$: Normal with dialog (default).
 $k=1$: Kills with no dialog.
 $k=2$: Disables killing.
 The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

All tests define the null hypothesis by

$H_0: \sigma_1^2 = \sigma_2^2 = \dots = \sigma_k^2$ against the alternative $H_a: \sigma_i^2 \neq \sigma_j^2$ for at least one $i \neq j$

Bartlett's test computes:

$$T = \frac{(n-k)\ln(\sigma_w^2) - \sum_{i=1}^k (n_i - 1)\ln(\sigma_i^2)}{1 + \frac{1}{3(k-1)} \left[\sum_{i=1}^k \frac{1}{n_i - 1} - \frac{1}{N - k} \right]}$$

where σ_i^2 is the variance of the i th wave, N is the sum of the points of all the waves, n_i is the number of points in wave i , and k is the number of waves. The weighted variance is given by

$$\sigma_w^2 = \sum_{i=1}^k \frac{(n_i - 1)\sigma_i^2}{N - k}$$

H_0 is rejected if T is greater than the critical value taken from the χ^2 distribution computed by solving for x :

$$1 - \alpha = 1 - \text{gamma}\left(\frac{k-1}{2}, \frac{x}{2}\right)$$

Levene's test computes:

$$W = \frac{(N-k) \sum_{i=1}^k n_i (\bar{Z}_i - \bar{Z})^2}{(k-1) \sum_{i=1}^k \sum_{j=1}^{n_i} (Z_{ij} - \bar{Z}_i)^2}, \text{ and } W = \frac{(N-k) \sum_{i=1}^k n_i (\bar{Z}_i - \bar{Z})^2}{(k-1) \sum_{i=1}^k \sum_{j=1}^{n_i} (Z_{ij} - \bar{Z}_i)^2}$$

where $Z_{ij} = |Y_{ij} - \bar{Y}_i|$, $\bar{Z}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} Z_{ij}$, $\bar{Z} = \frac{1}{N} \sum_{i=1}^k \sum_{j=1}^{n_i} Z_{ij}$, \bar{Y}_i depends on /METH.

H_0 is rejected if W is greater than the critical value from the F distribution computed by solving for x :

$$1 - \alpha = 1 - \text{beta}\left(\frac{v_2}{2}, \frac{v_1}{2}, \frac{v_2}{v_2 + v_1 x}\right)$$

StatsWaldCDF

StatsWaldCDF(*x*, *m*, *l*)

The StatsWaldCDF function returns the numerically evaluated inverse Gaussian or Wald cumulative distribution function.

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWaldPDF** function.

StatsWaldPDF

StatsWaldPDF(*x*, *m*, *l*)

The StatsWaldPDF function returns the inverse Gaussian or Wald probability distribution function

$$f(x, \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left[-\frac{\lambda(x - \mu)^2}{2\mu^2 x}\right] \text{ where } x, m, l > 0.$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWaldCDF** function.

StatsWatsonUSquaredTest

StatsWatsonUSquaredTest [*flags*] *srcWave1*, *srcWave2*

The StatsWatsonUSquaredTest operation performs Watson's nonparametric two-sample U^2 test for samples of circular data. Output is to the W_WatsonUtest wave in the current data folder or optionally to a table.

Flags

/ALPH = <i>val</i>	Sets the significance level (default <i>val</i> =0.05).
/Q	No results printed in the history area.
/T= <i>k</i>	Displays results in a table. <i>k</i> specifies the table behavior when it is closed. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
/Z	Ignores errors.

Details

The input waves, *srcWave1* and *srcWave2*, each must contain at least two angles in radians (mod 2π), can have any number of dimensions, and can be single or double precision; the waves must not contain any NaNs or INFs.

The Watson U^2 H_0 postulates that the two samples came from the same population against the different populations alternative. In the calculation, StatsWatsonUSquaredTest ranks the two inputs, accounts for possible ties, computes the test statistic U^2 , and compares it with the critical value. Because of the difficulty of computing the critical values, it always computes first the approximation due to Tiku and if possible it

computes the exact critical value using the method outlined by Burr. You can evaluate the U2 CDF to get more information about the critical region.

V_flag will be set to -1 for any error and to zero otherwise.

References

We have found that this method leads to slightly different results depending on the compiler and the system on which it is implemented:

StatsWatsonWilliamsTest

StatsWatsonWilliamsTest [*flags*] [*srcWave1*, *srcWave2*, *srcWave3*,...]

The StatsWatsonWilliamsTest operation performs the Watson-Williams test for two or more sample means. Output is to the W_WatsonWilliams wave in the current data folder or optionally to a table.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).
 /Q No results printed in the history area.
 /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.
 The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
 /WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
 /Z Ignores errors.

Details

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians, can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Watson-Williams H_0 postulates the equality of the means from all samples against the simple inequality alternative. The test computes the sums of the sines and cosines from which it obtains a weighted *r* value (*rw*). According to Mardia, you should use different statistics depending on the size of *rw*: for *rw*>0.95 use the simple F statistic, but for 0.95>*rw*>0.7 you should use the F-statistic with the K correction factor. Otherwise you should use the t-statistic. StatsWatsonWilliamsTest computes both the (corrected) F-statistic and the t-statistic as well as their corresponding critical values.

V_flag will be set to -1 for any error and to zero otherwise.

StatsWeibullCDF

StatsWeibullCDF(x, m, s, g)

The StatsWeibullCDF function returns the Weibull cumulative distribution function

$$F(x, \mu, \sigma, \gamma) = 1 - \exp \left[- \left(\frac{x - \mu}{\sigma} \right)^\gamma \right], \quad x \geq \mu \text{ and } \sigma, \gamma > 0$$

See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWeibullPDF** and **StatsInvWeibullCDF** functions.

StatsWeibullPDF

StatsWeibullPDF(x, m, s, g)

The StatsWeibullPDF function returns the Weibull probability distribution function

$$f(x, \mu, \sigma, \gamma) = \frac{\gamma}{\sigma} \left(\frac{x - \mu}{\sigma} \right)^{\gamma-1} \exp \left[- \left(\frac{x - \mu}{\sigma} \right)^\gamma \right]$$

where m is the location parameter, s is the scale parameter, and g is the shape parameter with $x \geq m$ and $s, g > 0$.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsWeibullCDF** and **StatsInvWeibullCDF** functions.

StatsWheelerWatsonTest

StatsWheelerWatsonTest [flags] [srcWave1, srcWave2, srcWave3, ...]

The StatsWheelerWatsonTest operation performs the nonparametric Wheeler-Watson test for two or more samples. Output is to the W_WheelerWatson wave in the current data folder or optionally to a table.

Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /Q No results printed in the history area.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
- k*=0: Normal with dialog (default).
- k*=1: Kills with no dialog.
- k*=2: Disables killing.
- The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /WSTR=*waveListString* Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
- /Z Ignores errors.

Details

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians (mod 2π), can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Wheeler-Watson H_0 postulates that the samples came from the same population. The extension of the test to more than two samples is due to Mardia. The Wheeler-Watson test is not valid for data with ties, in which case you should use Watson's U^2 test.

V_flag will be set to -1 for any error and to zero otherwise.

References

Mardia, K.V., *Statistics of Directional Data*, Academic Press, New York, New York, 1972.

See, in particular, Chapter 27 of:

Zar, J.H., *Biostatistical Analysis*, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsWatsonUSquaredTest** and **StatsWheelerWatsonTest**.

StatsWilcoxonRankTest

StatsWilcoxonRankTest [*flags*] *waveA*, *waveB*

The StatsWilcoxonRankTest operation performs the nonparametric Wilcoxon-Mann-Whitney two-sample rank test or the Wilcoxon Signed Rank test (for paired data) on *waveA* and *waveB*. Output is to the W_WilcoxonTest wave in the current data folder or optionally to a table.

Flags

- /ALPH = *val* Sets the significance level (default *val*=0.05).
- /APRX=*m* Sets the approximation method. It computes an exact critical value by default.
 - m*=1: Standard normal approximation with ties (Zar P. 151).
 - m*=2: Improved normal approximation (Zar P. 152).

Approximations may be appropriate for large sample sizes when computation may take a long time.
- /Q No results printed in the history area.
- /T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.
 - k*=0: Normal with dialog (default).
 - k*=1: Kills with no dialog.
 - k*=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /TAIL=*tail* Specifies the tail tested.
 - tail*=1: Lower tail.
 - tail*=2: Upper tail.
 - tail*=4: Two tail.

You can perform any combination of tests by adding their corresponding tail values (/TAIL=7 tests all tail possibilities). Note that H0 changes according to the selected tail.
- /WSRT Performs the Wilcoxon Signed Rank Test for paired data. The testh computes statistics Tp and Tm, lower-tail, upper-tail, and two-tail P-values. If the number of samples is less than 200 it computes exact P-values, otherwise they are computed using the normal approximation. Do not use /ALPH, /APRX, and /TAIL with this flag.
- /Z Ignores errors.

Details

The Wilcoxon-Mann-Whitney test combines the two samples and ranks them to compute the statistic *U*. If *waveA* has *m* points and *waveB* has *n* points, then *U* is given by

$$U = mn + \frac{m(m+1)}{2} - R_1$$

with the corresponding statistic *U'* given by

$$U' = mn + \frac{n(n+1)}{2} - R_2 \text{ where } R_i \text{ is the ranks of data in the } i\text{th wave (ranked in ascending order).}$$

The distribution of *U* is difficult to compute, requiring the number of possible permutations of *m* elements of *waveA* and *n* elements of *waveB* that give rise to *U* values that do not exceed the one computed. The distribution is computed according to the algorithm developed by Klotz. With increasing sample size one can avoid the time consuming distribution computation and use a normal approximation instead. Klotz recommends this approximation for $N=m+n \sim 100$.

Use /APRX=2 for the best approximation. The two approximations are discussed by Zar.

The Wilcoxon Signed Rank Test, or Wilcoxon Paired-Sample Test, ranks the difference between pairs of values and computes the sums of the positive ranks (Tp) and the negative ranks (Tm). It calculates Tp and Tm and P-values for all tail combinations. The P-values are:

P_lower_tail P(Wp<=Tp)

P_upper_tail P(Wp>=Tp)

P_two_tail 2*Min(P_lower_tail,P_upper_tail)

Wp is the generic symbol for the sum of positive ranks for the given number of pairs.

V_flag will be set to -1 for any error and to zero otherwise.

StatsWRCorrelationTest

StatsWRCorrelationTest [*flags*] *waveA*, *waveB*

The StatsWRCorrelationTest operation performs a Weighted Rank Correlation test on *waveA* and *waveB*, which contain the ranks of sequential factors. It computes a top-down correlation coefficient using Savage sums as well as the critical and P-values. Output is to the W_StatsWRCorrelationTest wave in the current data folder or optionally to a table.

Flags

/ALPH = *val* Sets the significance level (default *val*=0.05).

/Q No results printed in the history area.

/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z Ignores errors.

Details

The StatsWRCorrelationTest input waves must be one-dimensional and have the same length. The waves are 1-based, integer ranks of factors corresponding to the point number. Ranks may have ties in which case you should repeat the rank value. For example, if the second and third entries have the same rank you should enter {1,2,2,4}. H_0 stipulates that the same factors are most important in both groups represented by *waveA* and *waveB*.

The top-down correlation is the sum of the product of Savage sums for each row:

$$r_{TD} = \frac{\sum_{i=1}^n S_{iA} S_{iB} - n}{n - S_i} \text{ where } n \text{ is the number of rows and the Savage sum } S_i \text{ is } S_i = \sum_{j=1}^i \frac{1}{j}$$

and S_{iA} corresponds to the S_i value of the rank of the data in row (*i*-1) of *waveA*.

stopMSTimer

stopMSTimer (timerRefNum)

The stopMSTimer function frees up the timer associated with the *timerRefNum* and returns the number of elapsed microseconds since startMSTimer was called for this timer.

Parameters

timerRefNum is the value returned by startMSTimer or the special values -1 or -2. If *timerRefNum* is not valid then stopMSTimer returns 0. Passing -1 returns the clock frequency of the timer and, on the Macintosh, performs a calibration. Passing -2 returns the time in microseconds since the computer was started.

Details

If you want to make sure that all timers are free, call stopMSTimer ten times with *timerRefNum* equal to 0 through 9. It is OK to stop a timer that you never started.

On the Macintosh, the first call to stopMSTimer will take longer (approximately 0.1 sec. more) because of a clock frequency calibration. This will also happen when calling with a value of -1. If the extra time for the first call will cause problems, be sure to force the calibration before your first real timing run.

Examples

How long does an empty loop take on your computer?

```
Function TestMSTimer()  
    Variable timerRefNum  
    Variable microSeconds  
    Variable n  
  
    timerRefNum = startMSTimer  
    if (timerRefNum == -1)  
        Abort "All timers are in use"  
    endif  
    n=10000  
    do  
        n -= 1  
    while (n > 0)  
    microSeconds = stopMSTimer(timerRefNum)  
    Print microSeconds/10000, "microseconds per iteration"  
End
```

See Also

The **startMSTimer** and **ticks** functions.

str2num

str2num (str)

The str2num function returns a number represented by the string expression *str*.

Details

str2num returns NaN if *str* does not contain the text for a number.

str2num skips leading spaces and tabs.

See Also

The **sscanf** operation for more complex parsing jobs.

Strconstant

Strconstant ksName="literal string"

The Strconstant declaration defines the string *literal string* under the name *ksName* for use by other code, such as in a switch construct.

String

See Also

The **Constant** keyword for numeric types, **Constants** on page IV-38, and **Switch Statements** on page IV-33.

String

String [/G] *strName* [=*strExpr*][, *strName* [=*strExpr*]...]

The String declaration creates string variables and gives them the specified names.

Flags

/G Creates a global string. Overwrites any existing string with the same name.

Details

The string variable is initialized when it is created if you supply the =*strExpr* initializer. You can create more than one string variable at a time by separating the names and optional initializers with commas.

If used in a procedure, the new string is local to that procedure unless the /G (global) flag is used. If used on the command line, String is equivalent to String/G.

strName can optionally include a data folder path.

StringByKey

StringByKey(*keyStr*, *kwListStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]])

The StringByKey function returns a substring extracted from *kwListStr* based on the specified key contained in *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use StringByKey to extract a string value from a string containing a "key1:value1;key2: value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If the key is not found or if any of the arguments is "" then a zero-length string is returned.

keySepStr, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

Details

keyStr is limited to 255 characters.

kwListStr is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next *listSepStr* is returned.

kwListStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

Only the first characters of *keySepStr* and *listSepStr* are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

Examples

```
Print StringByKey("BKEY", "AKEY:hello;BKEY:nok-nok") // prints "nok-nok"
Print StringByKey("KY", "KX=1;ky=hello", "=") // prints "hello"
Print StringByKey("KY", "KX:1,KY:joey", ":", ",") // prints "joey"
Print StringByKey("kz", "KZ:1st,kz:2nd", ":", ",") // prints "1st"
Print StringByKey("kz", "KZ:1st,kz:2nd", ":", ",", 1) // prints "2nd"
```

See Also

The **NumberByKey**, **RemoveByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

stringCRC

stringCRC(*inCRC*, *str*)

The stringCRC function returns 32-bit cyclic redundancy check value of bytes in *str* starting with *inCRC* which should be zero for the first (or only) set of bytes.

Details

Polynomial used is:

$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$

See crc32.c in the public domain source code for zlib for more information.

See Also

The WaveCRC function.

StringFromList

StringFromList(index, listStr [, listSepStr])

The StringFromList function returns the *index*th substring extracted from *listStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;".

Use StringFromList to extract an item from a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

index is zero-based (set *index* to zero to get the first item in the string list).

If *index* < 0, or *index* ≥ the number of items in list, or if *listStr* or *listSepStr* is "", then a zero-length string is returned.

listSepStr is optional. When omitted, *listSepStr* is presumed to be ";".

Details

listStr is searched for an instance of the key string bound by *listSepStr* on the left and right. The text between the bounding *listSepStr*s is returned.

listStr is treated as if it ends with a *listSepStr* even if it doesn't.

Only the first character of *listSepStr* is used.

Examples

```
Print StringFromList(0, "wave0;wave1;")           // prints "wave0"
Print StringFromList(2, "wave0;wave1;")           // prints ""
Print StringFromList(1, "wave0;;wave2")           // prints ""
Print StringFromList(2, "fred\twilma\tbarney", "\t") // prints "barney"
```

A function that applies a unique line style to each trace in the top graph:

```
Function LineStyler()
  String traces= TraceNameList("",",",1)           // Traces in top graph
  String traceName
  Variable i=0
  do
    traceName= StringFromList(i,traces)
    if( strlen(traceName) == 0 )
      break
    endif
    ModifyGraph lstyle($traceName)= mod(i,18)       // 0 to 17, then repeat
    i += 1
  while (1)                                         // exit is via break statement
End
```

A function that converts a string list into a text wave:

```
Function List2Wave()
  String traces= TraceNameList("",",",1)           // Traces in top graph
  Variable n= ItemsInList(traces)
  MakeO/T/N=(n) textWave= StringFromList(p,traces)
End
```

See Also

The **AddListItem**, **ItemsInList**, **FindListItem**, **RemoveFromList**, **WaveList**, **WhichListItem**, **StringByKey**, **ListMatch**, **ControlNameList**, **TraceNameList**, **StringList**, **VariableList**, and **FunctionList** functions.

StringList

StringList(*matchStr*, *separatorStr*)

The StringList function returns a string containing a list of global string variables selected based on the *matchStr* parameter. The string variables listed are all in the current data folder.

Details

For a string variable name to appear in the output string, it must match *matchStr*. The first character of *separatorStr* is appended to each string variable name as the output string is generated.

The name of each string variable is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches all string variable names
"xyz"	Matches name xyz only
"*xyz"	Matches names which end with xyz
"xyz*"	Matches names which begin with xyz
"*xyz*"	Matches names which contain xyz
"abc*xyz"	Matches names which begin with abc and end with xyz

The list contains names only, without data folder paths. Thus, they are not suitable for accessing string variables outside the current data folder.

matchStr may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

"!*xyz"	Matches variable names which <i>do not</i> end with xyz
---------	---

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

Examples

StringList("*, ";")	Returns a list of all string variables in the current data folder.
StringList("S_*", ";")	Returns a list of all string variables in the current data folder whose names begin with "S_".

See Also

See the **VariableList** and **WaveList** functions.

stringmatch

stringmatch(*string*, *matchStr*)

The stringmatch function tests *string* for a match to *matchStr*. You may include asterisks in *matchStr* as a wildcard character. Returns 1 to indicate a match, or 0 for no match.

Details

matchStr is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches any string.
"xyz"	Matches the string "xyz" only.
"*xyz"	Matches strings ending with "xyz", for instance "abcxyz".
"xyz*"	Matches strings beginning with xyz, for instance "xyzpqr".
"*xyz*"	Matches strings containing xyz, for instance "abcxyzpqr".
"abc*xyz"	Matches strings beginning with abc and ending with xyz, for instance "abcpxrxyz".

If *matchStr* begins with the ! character, a match is indicated if *string* does *not* match *matchStr*. For example:

"!*xyz"	Matches strings which <i>do not</i> end with xyz.
---------	---

The ! character is considered to be a normal character if it appears anywhere else.

Note that matching is case-insensitive, so "xyz" also matches "XYZ" or "Xyz".

Also note that it is impossible to match an asterisk in *string*: use **GrepString** instead.

Among other uses, the stringmatch function can be used to build your own versions of the **WaveList** function, using **NameOfWave** and stringmatch to qualify names of waves found by **WaveRefIndexed**.

See Also

The **GrepString**, **cmpstr**, **strsearch**, **SplitString**, **ListMatch**, and **ReplaceString** functions and the **sscanf** operation.

strlen**strlen(*str*)**

The **strlen** function returns the number of characters in the string expression *str*.

strsearch**strsearch(*str*, *findThisStr*, *start* [, *options*])**

The **strsearch** function returns the numeric position of the string expression *findThisStr* in the string expression *str*.

Details

strsearch performs a case-sensitive search.

strsearch returns -1 if *findThisStr* does not occur in *str*.

The search starts from the character position in *str* specified by *start*; 0 is the first character in *str*.

strsearch limits *start* to one less than the length of *str*, so it is useful to use **Inf** for *start* when searching backwards to ensure that the search is from the end of *str*.

The optional *options* parameter is a bitmask specifying the search options:

- 1: Search backwards from *start*.
- 2: Ignore case.
- 3: Search backwards and ignore case.

Examples

```
String str="This is a test isn't it?"
Print strsearch(str,"test",0)           // prints 10
Print strsearch(str,"TEST",0)          // prints -1
Print strsearch(UpperStr(str),"TEST",0) // prints 10
Print strsearch(str,"TEST",0,2)        // prints 10
Print strsearch(str,"is",0)            // prints 2
Print strsearch(str,"is",3)            // prints 5
Print strsearch(str,"is",Inf,1)        // prints 15
```

See Also

The **sscanf** operation and **FindListItem** and **ReplaceString** functions.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

strswitch-case-endswitch**strswitch(<*string expression*>)**

case <*literal*><*constant*>:

 <*code*>

 [**break**]

[**default**:

 <*code*>]

endswitch

A **strswitch-case-endswitch** statement evaluates a string expression. If a case label matches *string expression*, then execution proceeds with *code* following the matching case label. When none of the cases match, execution will continue at the default label, if it is present, or otherwise the **strswitch** will be exited with no action taken. Note that although the **break** statement is optional, in almost all case statements it will be required for the **strswitch** to work correctly.

See Also

Switch Statements on page IV-33, **default** and **break** for more usage details.

STRUCT

STRUCT *structureName localName*

STRUCT is a reference that creates a local reference to a Structure accessed in a user-defined function. When a Structure is passed to a user function, it can only be passed by reference, so in the declaration within the function you must use *&localStructName* to define the function input parameter.

See Also

Structures in Functions on page IV-61 for further information.

See the **Structure** keyword for creating a Structure definition.

StructGet

StructGet [/B=*b*] *structVar*, *waveStruct*[[*colNum*]]

StructGet /S [/B=*b*] *structVar*, *strStruct*

The StructGet operation reads binary numeric data from a specified column of a wave or from a string variable and copies the data into the designated structure variable. The source wave or string will have been filled beforehand by **StructPut**.

Parameters

structVar is the name of an existing structure that is to be filled with new data values.

waveStruct is the name of a wave containing binary numeric data that will be used to fill *structVar*. Use the optional *colNum* parameter to specify a column from the structure wave. The contents of *waveStruct* are created beforehand using StructPut.

strStruct is the name of a string variable containing binary numeric data. The contents of *strStruct* are created beforehand using StructPut.

Flags

/B=*b* Sets the byte ordering for reading of structure data.

b=0: Reads in native byte order.

b=1: Reads bytes in reversed order.

b=2: Default; reads data in big-endian, high-byte order (Motorola/Macintosh).

b=3: Reads data in little-endian, low-byte order (Intel/Windows).

/S Reads binary data from a string variable, which was set previously with StructPut.

Details

The data that are stored in *waveStruct* and *strStruct* are in binary format so you can not directly view a meaningful representation of their contents by printing them or viewing the wave in a table. To view the contents of *waveStruct* or *strStruct* you must use StructGet to export them back into a structure and then retrieve the members.

If *colNum* is out of bounds it will be clipped to valid values and an error reported. If the row dimension does not match the structure size, as much data as possible will be copied to the structure.

By default, data are read in big-endian, high-byte order (Motorola/Macintosh). This allows data written on one platform to be read on the other.

See Also

The **StructPut** operation for writing structure data to waves or strings.

StructPut

StructPut [/B=*b*] *structVar*, *waveStruct*[[*colNum*]]

StructPut /S [/B=*b*] *structVar*, *strStruct*

The StructPut operation copies the binary numeric data in a structure variable to a specified column in a wave or to a string variable. The data in the wave or string can be read out into another structure using **StructGet**.

Parameters

structVar is the name of a structure from which data will be exported.

waveStruct is the name of an existing wave to which data will be exported. Use the optional *colNum* parameter to specify a column in *waveStruct* to contain the data. The first column of *waveStruct* will be filled if *colNum* is omitted.

strStruct is the name of an existing string variable to which data will be exported.

Flags

/B=*b* Sets the byte ordering for writing of structure data.
 b=0: Writes in native byte order.
 b=1: Writes bytes in reversed order.
 b=2: Default; writes data in big-endian, high-byte order (Motorola/Macintosh).
 b=3: Writes data in little-endian, low-byte order (Intel/Windows).
 /S Writes binary data to a string variable.

Details

The structure to be exported must contain only numeric data in either integer, floating point, or double precision format. If the structure contains any objects such as String, NVAR, WAVE, etc., then an error will result at compile time.

If needed, StructPut will redimension *waveStruct* to unsigned byte format, will set the number of rows to equal the size of the structure, and set the column dimension large enough to accommodate the size specified by *colNum*. You can think of *waveStruct* as a one-dimensional array of structure contents indexed by *colNum* although the wave is actually two-dimensional with each column containing a copy of a separate structure.

By default, data are written in big-endian, high-byte order (Motorola/Macintosh). This allows data written on one platform to be read on the other.

After you have exported the structure data to *waveStruct* or *strStruct* they will contain binary data that you cannot inspect directly. To view the contents of *waveStruct* or *strStruct*, you must use the original structure or use StructGet to export them into another structure.

See Also

The **StructGet** operation for reading structure data from waves or strings.

Structure

Structure *structureName*

memType *memName* [*arraySize*] [, *memName* [*arraySize*]]

...

EndStructure

The Structure keyword introduces a structure definition in a user function. Within the body of the structure you declare the member type (*memType*) and the corresponding member name(s) (*memName*). Each *memName* may be declared with an optional array size.

Details

Structure member types (*memType*) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

Igor Member Type	C Equivalent	Byte Size
char	signed char	1
uchar	unsigned char	1
int16	short int	2
uint16	unsigned short int	2
int32	long int	4

StrVarOrDefault

Igor Member Type	C Equivalent	Byte Size
uint32	unsigned long int	4
float	float	4
double	double	8

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).

Each structure member may have an optional *arraySize* specification, which gives the number of elements contained by the structure member. The array size is an integer number of 1 to 100 elements.

See Also

Structures in Functions on page IV-61 for further information.

See the **STRUCT** declaration for creating a local reference to a Structure.

StrVarOrDefault

StrVarOrDefault(*pathStr*, *defStrVal*)

The StrVarOrDefault function checks to see if *pathStr* points to a string variable and if so, it returns its value. If the string variable does not exist, returns *defStrVal* instead.

Details

StrVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. Numeric variables use the corresponding numeric function, **NumVarOrDefault**.

Examples

```
Macro foo(nval,sval)
  Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav",2)
  String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")

  String dfSav= GetDataFolder(1)
  NewDataFolder/O/S root:Packages
  NewDataFolder/O/S mypack
  Variable/G nvalSav= nval
  String/G svalSav= sval
  SetDataFolder dfSav
End
```

StudentA

StudentA(*t*, *DegFree*)

The StudentA function returns the area from $-t$ to t under the Student's T distribution having *DegFree* degrees of freedom. That is, it returns the probability that a random sample from Student's T is between $-t$ and t .

Note that this is the *bi-tail* result. That is, it gives the area from $-t$ to t , rather than the cumulative area from $-\infty$ to t . It is this latter number that is commonly tabulated- StudentA returns the probability $1-\alpha$ where the area from $-\infty$ to t is the probability $1-\alpha/2$.

StudentA tests whether a normally-distributed statistic is significantly different from a certain value. You could use it to test whether an intercept from a line fit is significantly different from zero:

```
Make/O/N=20 Data=0.5*x+2+gnoise(1)           // line with Gaussian noise
Display Data
CurveFit line Data /D
print "Prob = ", StudentA(W_coef[0]/W_sigma[0], V_npnts-2)
```

Because the noise is random, the results will differ slightly each time this is tried. When we did it, the result was:

```
Prob = 0.999898
```

which indicates that the intercept of the line fit was different from zero with 99.99 per cent probability.

StudentT

StudentT(*Prob*, *DegFree*)

The StudentT function returns the t value corresponding to an area *Prob* under the Student's T distribution from $-t$ to t for *DegFree* degrees of freedom.

Note that this is a *bi-tail* result, which is what is usually desired. Tabulated values of the Student's T distribution are commonly the one-sided result.

StudentT calculates confidence intervals from standard deviations for normally-distributed statistics. For instance, you can use it to calculate a confidence interval for the coefficients from a curve fit:

```
Make/O/N=20 Data=0.5*x+2+gnoise(1)           // line with Gaussian noise
Display Data
CurveFit line Data /D
print "intercept = ", W_coef[0], "±", W_sigma[0]*StudentT(0.95, V_npnts-2)
print "slope = ", W_coef[1], "±", W_sigma[1]*StudentT(0.95, V_npnts-2)
```

See Also

Chapter III-12, **Statistics** for a function and operation overview.

Submenu

Submenu *menuNameStr*

The Submenu keyword introduces a submenu definition. It is used inside a Menu definition. See Chapter IV-5, **User-Defined Menus** for further information.

sum

sum(*waveName* [, *x1*, *x2*])

The sum function returns the sum of the wave elements for points from $x=x1$ to $x=x2$.

Details

The X scaling of the wave is used only to locate the points nearest to $x=x1$ and $x=x2$. To use point indexing, replace *x1* with `pnt2x(waveName,pointNumber1)`, and a similar expression for *x2*.

If *x1* and *x2* are not specified, they default to $-\infty$ and $+\infty$, respectively.

If the points nearest to *x1* or *x2* are not within the point range of 0 to `numpts(waveName)-1`, sum limits them to the nearest of point 0 or point `numpts(waveName)-1`.

If any values in the point range are NaN, sum returns NaN.

Examples

```
Make/O/N=100 data;SetScale/I x 0,Pi,data
data=sin(x)
Print sum(data,0,Pi)           // the entire point range, and no more
Print sum(data)                // same as -infinity to +infinity
Print sum(data,Inf,-Inf)       // +infinity to -infinity
```

The following is printed to the history area:

```
•Print sum(data,0,Pi)           // the entire point range, and no more
  63.0201
•Print sum(data)                // same as -infinity to +infinity
  63.0201
•Print sum(data,Inf,-Inf)       // +infinity to -infinity
  63.0201
```

See Also

mean and **area** functions.

SVAR

SVAR [/Z] *localName* [= *pathToStr*][, *localName1* [= *pathToStr1*]]...

SVAR is a reference that creates a local reference to a global string variable accessed in a user-defined function.

The SVAR reference is required when you access a global string variable in a function. At compile time, the SVAR statement specifies a local name referencing a global string variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global string variable must exist when the SVAR statement is executed.

SVAR_Exists

When *localName* is the same as the global string variable name and you want to reference a global variable in the current data folder, you can omit *pathToStr*. Prior to Igor Pro 4.0, *pathToStr* was always required.

pathToStr can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-48).

If the global variable may not exist at runtime, use the /Z flag and call **SVAR_Exists** before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

```
SVAR/Z nv=<pathToPossiblyMissingStringVariable>
if( SVAR_Exists(sv) )
    <do something with sv>
endif
```

Note that to create a global string variable, you use the **String/G** operation.

Flags

/Z ignores string reference checking failures.

See Also

SVAR_Exists function and **Accessing Global Variables and Waves** on page IV-49.

Runtime Lookup of Globals on page IV-50.

Converting a String into a Reference Using \$ on page IV-48.

SVAR_Exists

SVAR_Exists(name)

The **SVAR_Exists** function returns one if the specified SVAR reference is valid or zero if not. Used only in user-defined functions.

For example if, in a user function, you have:

```
SVAR var1= MyGlobalVar
print SVAR_Exists(var1)
```

will print 1 if MyGlobalVar is present in the current data folder.

See Also

WaveExists, **NVAR_Exists**, and **Accessing Global Variables and Waves** on page IV-49.

switch-case-endswitch

```
switch(<numeric expression>)
    case <literal><constant>:
        <code>
        [break]
    [default:
        <code>]
endswitch
```

A switch-case-endswitch statement evaluates a numerical expression. If a case label matches *numerical expression*, then execution proceeds with *code* following the matching case label. When no cases match, execution will continue at the default label, if present, or otherwise the switch will be exited with no action taken. Note that although the break statement is optional, in almost all case statements it will be required for the switch to work correctly.

See Also

Switch Statements on page IV-33, **default** and **break** for more usage details.

t

t

The **t** function returns the **T** value for the current chunk of the destination wave when used in a multidimensional wave assignment statement. **T** is the scaled chunk index while **s** is the chunk index itself.

Details

Unlike **x**, outside of a wave assignment statement, **t** does not act like a normal variable.

See Also

Waveform Arithmetic and Assignments on page II-80.

For other dimensions, the **p**, **q**, **r**, and **s** functions.

For scaled dimension indices, the **x**, **y**, and **z** functions.

TabControl

TabControl [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The **TabControl** operation creates tab panels for controls.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the **TabControl** to be created or changed.

key is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of **default**, **native**, or **os9**.

platform can be one of **Mac**, **Win**, or **All**.

See **DefaultGuiControls Default Fonts and Sizes** for how enclosed controls are affected by native **TabControl** appearance.

See **Button** for more appearance details.

disable=*d*

Sets user editability of the control.

d=0: Normal.

d=1: Hidden.

d=2: Draw in gray state; disable control action.

font="fontName"

Sets the font used for tabs, e.g., font="Helvetica".

fs=*s*

Sets the font size for tabs.

fstyle=*fs*

fs is a binary coded number with each bit controlling one aspect of the font style as follows:

bit 0: Bold.

bit 1: Italic.

bit 2: Underline.

bit 3: Outline (*Macintosh only*).

bit 4: Shadow (*Macintosh only*).

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

labelBack=(*r,g,b*) or 0

Sets fill color for current tab and the interior. *r*, *g*, and *b* are integers from 0 to 65535. If not set, then interior is transparent and the current tab is filled with the window background. Note that if you use a fill color, draw objects can not be used because they will be covered up.

noproc

Specifies that no function is to run when clicking a tab.

pos={*left,top*}

Sets absolute location in pixels.

proc=*procName*

Specifies the function to run when the tab is pressed. Your function must hide and show other controls as desired. The **TabControl** does not do this automatically.

size={*width,height*}

Sets **TabControl** size in pixels.

TabControl

`tabLabel(n)=lbl` Sets *n*th tab label to *lbl*. Set the label of the last tab to "" to reduce the number of tabs.

`userdata(UDName)=UDStr` Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create.

`userdata(UDName)+=UDStr` Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.

`value=v` Sets current tab number. Tabs count from 0.

`win=winName` Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The action procedure for a TabControl can use a predefined structure `WMTabControlAction` as a parameter to the function. The control will use this more efficient method when the function properly matches the structure prototype for a TabControl, otherwise it will use the old-style method.

A TabControl action procedure using a structure has the format:

```
Function newActionProcName(TC_Struct)
    STRUCT WMTabControlAction &TC_Struct
    ...
End
```

For a TabControl, the `WMTabControlAction` structure has members as described in the following table:

WMTabControlAction Structure Members

Member	Description						
<code>char ctrlName[MAX_OBJ_NAME+1]</code>	Control name.						
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window.						
<code>STRUCT Rect winRect</code>	Local coordinates of host window.						
<code>STRUCT Rect ctrlRect</code>	Enclosing rectangle of the control.						
<code>STRUCT Point mouseLoc</code>	Mouse location.						
<code>Int32 eventCode</code>	Event that executed the procedure. <table><tr><th>eventCode</th><th>Event</th></tr><tr><td>-1</td><td>Control being killed</td></tr><tr><td>2</td><td>Mouse up</td></tr></table>	eventCode	Event	-1	Control being killed	2	Mouse up
eventCode	Event						
-1	Control being killed						
2	Mouse up						
<code>Int32 eventMod</code>	Bitfield of modifiers. See description of MODIFIERS : flags for SetWindow under Unnamed Hooks on page V-505.						
<code>String userdata</code>	Primary (unnamed) user data. If this changes, it is written back automatically.						
<code>Int32 tab</code>	Tab number.						

Action functions should respond only to documented `eventCode` values. Other event codes may be added along with more fields. Although the return value is not currently used, action functions should always return zero.

The constants used to specify the size of structure `char` arrays are internal to Igor Pro and may change.

When clicking a TabControl with the selector arrow, click in the title region. The control will not be selected if you click in the body. This is to make it easier to select controls in the body rather than the TabControl itself.

TabControls may be used to simplify complex control panels. If you are not already familiar with the concept of a TabControl, see **Modifying Axes** on page II-242 for an illustration of tabs as used in the Modify Axis dialog.

Designing a TabControl with all the accompanying interior controls can be somewhat difficult. Here is a suggested technique:

First, create and set the size and label for one tab. Then create the various controls for this first tab. Before starting on the 2nd tab, create the TabControl's procedure so that it can be used to hide the first set of controls. Then add the 2nd tab, click it to run your procedure and start adding controls for this new tab. When done, update your procedure so the new controls will be hidden when you start on the third tab. You may find it useful to create a recreation macro of your panel to get a convenient listing of the controls. Here is an example:

(The commands given include size and position information obtained by manual adjustment.)

1. Create a panel and a TabControl:

```
NewPanel /W=(150,50,478,250)
ShowTools
TabControl foo,pos={29,38},size={241,142},tabLabel(0)="first tab",value=0
```

2. Add a few controls to the interior of the TabControl:

```
Button button0,pos={52,72},size={50,20},title="First"
CheckBox check0,pos={52,105},size={102,15},title="Check first",value=0
```

3. Write a function:

```
Function fooProc(name,tab)
    String name
    Variable tab

    Button button0,disable= (tab!=0)
    CheckBox check0,disable= (tab!=0)
End
```

4. Set proc and add a new tab:

```
TabControl foo,proc=fooProc,tabLabel(1)="second tab"
```

5. Click the second tab (which hides the first tab's controls) and then add new controls like so:

```
Button button1,pos={58,73},size={50,20},title="Second"
CheckBox check1,pos={60,105},size={114,15},title="Check second",value= 0
```

6. Finally, change fooProc by adding these lines at the end:

```
Button button1,disable= (tab!=1)
CheckBox check1,disable= (tab!=1)
```

See Also

The **ControlInfo** operation for information about the control along with the **ModifyControl** and **ModifyControlList** operations. Chapter III-14, **Controls and Control Panels**, for details about control panels and controls. The **GetUserData** operation for retrieving named user data.

Table

Table

Table is a procedure subtype keyword that identifies a macro as being a table recreation macro. It is automatically used when Igor creates a window recreation macro for a table. See **Procedure Subtypes** on page IV-149 and **Killing and Recreating a Table** on page II-179 for details.

TableStyle

TableStyle

TableStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Table dialog and in the Table Macros menu. See **Table Style Macros** on page II-211 for details.

TableInfo

TableInfo(winNameStr, itemIndex)

The TableInfo function returns a string containing a semicolon-separated list of keywords and values that describe a column in a table or overall properties of the table. The main purpose of TableInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges a table or which manipulates the table selection.

TableInfo

Parameters

winNameStr is the name of an existing table window or "" to refer to the top table.

itemIndex is one of the following:

<i>itemIndex</i> Value	Returns
-2	Information about the table as a whole.
-1	Information about the Point column
≥ 0	Information about a column other than the Point column. 0 refers to the first column after the Point column, 1 refers to the second column after the Point column, and so on.

TableInfo returns "" in the following situations:

winNameStr is "" and there are no table windows.

winNameStr is a name but there are no table windows with that name.

itemIndex not -2 and is out of range for an existing column.

Details

If *itemIndex* is -2, the returned string describes the table as a whole and contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
TABLERNAME	The name of the table.
HOST	The host specification of the table's host window if it is a subwindow or "" if it is a top-level table window.
ROWS	Number of used rows in the table.
COLUMNS	Number of used columns in the table including the Point column.
SELECTION	A description of the table selection as you would specify it when invoking the ModifyTable operation's selection keyword.
FIRSTCELL	An identification of the first visible data cell in the top/left corner of the table in row-column format. The first data cell is at location 0, 0.
LASTCELL	An identification of the last visible data cell in the bottom/right corner of the table in row-column format.
TARGETCELL	An identification of the target (highlighted) data cell in row-column format.
ENTERING	1 if an entry has been started in the entry line, 0 if not.

If *itemIndex* is -1 up to but not including the number of used columns to the right of the Point column, the returned string describes the specified column and contains the following keywords, with a semicolon after each keyword-value pair.

Keyword	Information Following Keyword
TABLERNAME	The name of the table.
HOST	The host specification of the table's host window if it is a subwindow or "" if it is a top-level table window.
COLUMNNAME	Name of the column as you would specify it to the Edit operation if you were creating a table showing just the column of interest.
TYPE	Column's type which will be one of the following: Unused, Point, Index, Label, Data, RealData, ImagData. "Index" identifies a index column such as the X values of a wave. "Label" identifies a column of dimension labels. "Data" identifies a data column of a scalar wave. RealData and ImagData identify a real or imaginary column of a complex wave.

Keyword	Information Following Keyword
INDEX	Column's position. -1 refers to the Point column, 0 to the first data column, and so on.
DATATYPE	Numeric data type of the wave or zero for text waves. See WaveType for a definition of data type codes.
WAVE	A full data folder path to the wave displayed in the column or " " for the Point column.
COLUMNS	The total number of columns in the table from the wave for the column for which you are getting information. This can be used to skip over all of the columns of a multidimensional wave.
HDIM	The wave dimension displayed horizontally as you move from one column to the next. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.
VDIM	The wave dimension displayed vertically in the column. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.
TITLE	As specified for the ModifyTable operation's title keyword.
WIDTH	Column's width in points.
FORMAT	As specified for the ModifyTable operation's format keyword.
DIGITS	As specified for the ModifyTable operation's digits keyword.
SIGDIGITS	As specified for the ModifyTable operation's sigDigits keyword.
TRAILINGZEROS	As specified for the ModifyTable operation's trailingZeros keyword.
SHOWFRACSECONDS	As specified for the ModifyTable operation's showFracSeconds keyword.
FONT	The name of the column's font.
SIZE	Column's font size.
STYLE	As specified for the ModifyTable operation's style keyword.
ALIGNMENT	0=left, 1=center, 2=right.
RGB	The column's color in R,G,B format.
ELEMENTS	As specified for the ModifyTable operation's elements keyword.

Examples

This example makes the table's target cell advance by one position within the range of selected cells each time it is called. To try it, create a table, select a range of cells and then run the function using the Macros menu.

```
Menu "Macros"
  "Test/1", /Q, AdvanceTargetCell("")
End

Function AdvanceTargetCell(tableName)
  String tableName          // Name of table or "" for top table.
  String info = TableInfo(tableName, -2)
  if (strlen(info) == 0)
    return -1              // No such table
  endif

  String selectionInfo
  selectionInfo = StringByKey("SELECTION", info)
  Variable fRow, fCol, lRow, lCol, tRow, tCol
  sscanf selectionInfo, "%d,%d,%d,%d,%d,%d", fRow, fCol, lRow, lCol, tRow, tCol
  tCol += 1
  if (tCol > lCol)
    tCol = fCol
    tRow += 1
    if (tRow > lRow)
```

/H= <i>legendSymbolWidth</i>	<i>legendSymbolWidth</i> sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.
/I= <i>i</i>	<p><i>i</i> =1: Tag will be invisible if it is “off screen”. “Off screen” means that its attachment point or any part of the tag’s text is off screen. This is esthetically pleasing but gives you nothing to grab if you want to drag the tag back on screen.</p> <p><i>i</i> =0: Tag will always be visible. If it is “off screen”, it appears at the extreme edge of the graph.</p>
/K	Kills existing tag.
/L= <i>line</i>	<p><i>line</i>=0: No line from tag to attachment point.</p> <p><i>line</i>=1: Line connecting tag to attachment point.</p> <p><i>line</i>=2: Line with arrow pointing from tag to attachment point.</p>
/LS= <i>linespace</i>	Specifies a tweak to the normal line spacing where <i>linespace</i> is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.
/M[= <i>sameSize</i>]	<p>/M or /M=1 specifies that legend markers should be the same size as the marker in the graph.</p> <p>/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.</p>
/N= <i>name</i>	Specifies name of the tag to create or change.
/O= <i>rot</i>	<p>Sets the text rotation in degrees counterclockwise. Valid values are -90, 0, 90, 180, or 270.</p> <p>0 is normal horizontal left-to-right text.</p> <p>90 is vertical bottom-to-top text, etc.</p>
/P= <i>tipOffset</i>	Sets the offset from the tip of a tag’s line or arrow to the point on the wave that it is tagging. <i>tipOffset</i> is a positive number from 0 to 200 in points. If <i>tipOffset</i> =0 (default), it automatically chooses an appropriate offset.
/Q[= <i>contourInstance</i>]	<p>Associates a tag with a particular contour level trace in a graph recreation macro. Of interest mainly to hard-core programmers.</p> <p>When “=<i>contourInstance</i>” is present, /Q associates the tag with the contour wave. Igor will feel free to change or delete the tag, as appropriate, when it recalculates the contour (because you changed the contour data or appearance, the graph size or the axis range). <i>contourInstance</i> is a contour instance name, such as <i>zWave</i> or <i>zWave#1</i> if you have the same wave contoured twice in the graph.</p> <p>/Q by itself, with “=<i>contourInstance</i>” not present, disassociates the tag from the contour wave. Igor will no longer modify or delete the tag (unless the contour level to which it is attached is deleted). If you manually tweak a contour label, using the Modify Annotation dialog, Igor uses this flag.</p>
/R= <i>newName</i>	Renames the tag.
/S= <i>style</i>	<p><i>style</i>=0: Single frame.</p> <p><i>style</i>=1: Double frame.</p> <p><i>style</i>=2: Triple frame.</p> <p><i>style</i>=3: Shadow frame.</p>
/T= <i>tabSpec</i>	<i>tabSpec</i> is a single number in points, such as /T=72, for evenly spaced tabs or a list of tab stops in points such as /T={50, 150, 225}.
/TL= <i>extLineSpec</i>	<p>Specifies extended tag line parameters similar to the SetDrawEnv arrow settings.</p> <p><i>extLineSpec</i> = {<i>keyword</i> = <i>value</i>,...} or zero to turn off all extended specifications.</p> <p>Valid <i>keyword-value</i> pairs are:</p> <p><i>len</i>=<i>l</i> Length of arrow head in points (<i>l</i>=0 for auto).</p> <p><i>fat</i>=<i>f</i> Width to length ratio of arrow head (default is 0.5 same as <i>f</i>=0).</p> <p><i>style</i>=<i>s</i> Sets barb side mode (see SetDrawEnv <i>astyle</i> for values).</p> <p><i>shar</i> =<i>s</i> Sets sharpness between -1 and 1 (default is 0; blunt).</p> <p><i>frame</i>=<i>f</i> Sets frame thickness in outline mode.</p>

	<i>lThick=l</i>	Sets line thickness in points (default is 0.5 for <i>l=0</i>).
	<i>lineRGB=(r,g,b)</i>	Sets color for lines. Default is all zeros (black); the same as the tag frame.
	<i>dash=d</i>	Specifies dash pattern number between 0 and 17 (see SetDashPattern for patterns).
<i>/W=winName</i>		Operates on the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
<i>/V=vis</i>	<i>vis=0:</i>	Invisible annotation; not selectable. The annotation is still listed in AnnotationList .
	<i>vis=1:</i>	Visible annotation (default).
<i>/X=xOffset</i>		Distance from point to tag as percentage of graph width. For axis tags, the offsets are proportional to the size of the text used for the axis labels.
<i>/Y=yOffset</i>		Distance from point to tag as percentage of graph height. For axis tags, the offsets are proportional to the size of the text used for the axis labels.
<i>/Z=freeZe</i>	<i>freeZe=1:</i>	Freezes tag position (you can't move it with the mouse).
	<i>freeZe=0:</i>	Unfreezes it.

Details

If the */C* flag is used, it must be the first flag in the command and must be followed immediately by the */N=name* flag.

If the */K* flag is used, it must be the first flag in the command and must be followed immediately by the */N=name* flag with no further flags or parameters.

traceOrAxisName, *xAttach*, and *textStr* are all optional. If *traceOrAxisName* is specified, then *xAttach* must be specified, and vice versa. *textStr* may be specified only if *traceOrAxisName* and *xAttach* are specified.

This syntax allows changes to the tag to be made through the *flags* parameters without needing to respecify the other parameters. Similarly, the tag's attachment point can be changed without needing to respecify the *textStr* parameter.

xAttach is in terms of the wave's X scaling. If *traceOrAxisName* is displayed as an XY pair, we recommend that you use "point scaling" for the waves, so that *xAttach* can be a point number (because *xAttach* will not be an X axis value).

A tag can have at most 100 lines.

textStr can contain the following escape codes which affect subsequent characters in string.

Note: These escape codes contain backslashes, which should themselves be preceded with another backslash. These are automatically inserted by the Add Annotation dialog, but must be manually added when writing a function or in the command line. See the discussion in the **TextBox** operation about backslashes in *textStr*.

The characters "<?>" in a tag indicate that you specified an invalid escape code or used a font that is not available.

The escape codes are:

<i>\B</i>	Use subscript (smaller type).
<i>\F'fontName'</i>	Use specified font (e.g., <i>\F 'Helvetica '</i>).
<i>\fdd</i>	<i>dd</i> is a binary coded number with each bit controlling one aspect of the column's font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>).

For example, bold underline is $2^0 + 2^2 = 1 + 4 = 5$. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

<code>\JR</code>	Right aligned text.
<code>\JC</code>	Center aligned text.
<code>\JL</code>	Left aligned text.
<code>\K(<i>r,g,b</i>)</code>	Use specified color for text. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>\M</code>	Use normal (main) script (reverts to main line and size).
<code>\S</code>	Use superscript (uses smaller type).
<code>\Znn</code>	Use font size <i>nn</i> (<i>nn</i> must be exactly two digits).
<code>\Znnnn</code>	<i>nnn</i> is a 3 digit percentage by which to change the current font size. (<i>nnn</i> must be exactly three digits).

textStr can also contain escape codes to manipulate text info variables (see **About Text Info Variables** on page III-61).

When specifying an axis tag, you can also use additional dynamic escape codes that are available with the **Label** operation.

textStr can also contain the following escape codes which insert dynamically computed substrings:

<code>\ON</code>	Inserts name of wave to which tag is attached.
<code>\On</code>	Inserts name of wave and its instance number (if greater than 0).
<code>\OP</code>	Inserts point number to which tag is attached.
<code>\OX</code>	Inserts X value of point to which tag is attached (<i>xAttach</i>).
<code>\OY</code>	Inserts Y value of point to which tag is attached.
<code>\OZ</code>	Inserts Z value of point to which tag is attached for contour level traces. Inserts NaN for other traces.
<code>\{<i>dynText</i>\}</code>	<i>dynText</i> is dynamically evaluated text, which is discussed below.

Dynamically evaluated text (*dynText*) may contain numeric and string expressions. Igor automatically reevaluates *dynText* when a numeric or string variable or wave referenced in *dynText* changes.

Note: When used in *dynText* expressions, user-defined numeric and string variables in macros or functions must be declared as global variables for the expression to evaluate correctly.

dynText can take two forms, an easy one for a single numeric expression and a more complex form that provides precise control over the formatting of the result.

The easy form is:

```
\{numeric-expression\}
```

This evaluates the expression and prints with generic ("%g") formatting.

The full form is:

```
\{formatStr, list-of-numeric-or-string-expressions\}
```

formatStr and *list-of-numeric-or-string-expressions* are treated as for **printf**.

As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. Rather than typing (in the Add Annotation dialog):

```
\{"twice K0 is %g, and today is %s",2*K0,date() }
```

you can type:

```
\{
    "twice K0 is %g, and today is %s",
    2*K0,
    date()
}
```

Carriage returns can be typed directly in the Add Annotations dialog, or they can be typed as "\r" in a macro, function or the command line. Since \r is not a tag escape sequence, only one backslash is needed. See the examples.

Examples

```
Tag/C/N=t1/X=25/Y=50
```

moves the tag named t1 to the location defined by X=25 and Y=50.

```
Tag/C/N=t1 wave1, 50
```

moves the tag named t1 to wave1 at x=50.

```
Tag/N=t2 wave1, 50, "\\JC\\{numpts(wave1)} points\\rin this wave"
```

creates a new tag on wave1 that looks like this:

128 points
in this wave

```
Tag w,0, "\\{"%g is first, %g is last\\rw[0],w[numpts(w)-1]]"
```

creates a new tag on w that looks like this:

0 is first, 31.75 is last

Observe how the "\r" in the *textStr* breaks the annotation text by examining the Modify Annotation dialog:

Following is an example of various ways in which axis tags can be used:

```
Make/O jack=sin(x/8)
SetScale x,0,14e9,"y" jack
Display jack
Label bottom "\\u#2" // turn off default axis label
ModifyGraph axOffset(bottom)=1.16667 // make room for tag (manual adjustment)
Tag/N=text0/F=0/A=MT/X=0.20/Y=-4.29/L=0 bottom, Nan, "\\JCTime (\\U)rGratuitous 2nd line"

// now a few "important location" tags...
Tag/N=text1/F=0/A=LB/X=1.20/Y=3.00 bottom, 0, "Big Bang"
Tag/N=text2/F=0/A=MB/X=0.00/Y=2.86 bottom, 8000000000, "Earth formed"
Tag/N=text3/F=0/A=RB/X=-0.80/Y=4.71 bottom, 13040000000, "Dinosaurs ruled"
```

See **About Text Info Variables** on page III-61 for *textStr* escape codes that manipulate text info variables and see the discussion in the **TextBox** operation about backslashes in *textStr*. The **AppendText** operation. For an explanation of graphing XY pairs, and X versus point scaling, see Chapter II-5, **Waves**.

For additional axis tag escape codes see the **Label** operation and **Axis Labels** on page II-259.

The **AnnotationList**, **AnnotationInfo**, **TagVal**, and **TagWaveRef** functions.

TagVal

TagVal (code)

TagVal is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a number reflecting some property of the tag and helps you to display information about the tagged wave. The property is selected by the *code* parameter:

<i>code</i>	Return Value
0	Similar to \OP, returns the tag attach point number.
1	Similar to \OX, returns the X coordinate of tag attachment in the graph. When a tag is attached to an XY pair of traces, the X coordinate will most likely be different than the tag's X scaling attachment value specified in the Tag command.
2	Similar to \OY, returns the Y coordinate of tag attachment in the graph or the Y axis value in a Waterfall plot.
3	Similar to \OZ, returns the Z coordinate of tag attachment in a contour, image, or Waterfall plot.
4	Similar to \Ox, returns the trace x offset.

<i>code</i>	Return Value
5	Similar to \Oy, returns the trace y offset.
6	Returns the X muloffset (with the not set value 0 translated to 1).
7	Returns the Y muloffset (with the not set value 0 translated to 1).

Because TagVal returns a numeric value, the result can be formatted any way you wish using the **printf** formatting codes. In contrast, the \O codes insert preformatted text, and you don't have control over the format.

TagVal is sometimes used in conjunction with the **TagWaveRef** function. For example, you might write a user-defined function that calculates a value as a function of a wave and a point number.

Examples

```
Tag wave0, 0, "Y value is \\{"%g\\",TagVal(2)}"
Tag wave0, 0, "Y value is \\{"%g\\",TagWaveRef()[TagVal(0)]}"
Tag wave0, 0, "Y value is \\OY"
```

These examples all produce identical results.

See Also

The **Tag** operation, the **TagWaveRef** function.

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

TagWaveRef

TagWaveRef()

TagWaveRef is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a wave reference to the wave that the tag is on and helps you to display information about the tagged wave. It is often used in conjunction with the **TagVal** function. You can pass the result of TagWaveRef to any function that takes a Wave parameter.

Examples

Show the name of the data folder containing the tagged wave:

```
Tag wave0, 0, "\\ON is in \\{"%s\\",GetWavesDataFolder(TagWaveRef(),0)}"
```

See Also

The **Tag** operation, the **TagVal** function

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

tan

tan(*angle*)

The tan function returns the tangent of *angle* which is in radians. In complex expressions, *num* is complex, and tan(*num*) returns a complex value.

tanh

tanh(*num*)

The tanh function returns the hyperbolic tangent of *num*. In complex expressions, *num* is complex, and tanh(*num*) returns a complex value.

TextBox

TextBox [*flags*] [*textStr*]

The TextBox operation puts a textbox on the target or named graph window. A textbox is an annotation that is not associated with any particular trace.

Parameters

textStr is the text that is to appear in the textbox. It is optional.

Flags

/A=*anchorCode* Specifies position of textbox anchor point.

<i>anchorCode</i>	Position	<i>anchorCode</i>	Position
LT	left top	RT	right top
LC	left center	RC	right center
LB	left bottom	RB	right bottom
MT	middle top		
MC	middle center		
MB	middle bottom		

anchorCode is a literal, *not* a string.

For interior textboxes, the anchor point is on the rectangular edge of the plot area of the graph window (where the left, bottom, right, and top axes are drawn).

For exterior textboxes, the anchor point is on the rectangular edge of the entire graph window.

/B=(r,g,b) Sets the color of the tag's background. *r*, *g*, and *b* specify the amount of red, green, and blue as an integer from 0 to 65535.

/B=b

- b=0:* Opaque background.
- b=1:* Transparent background.
- b=2:* Same background as the graph's plot area background.
- b=3:* Same background as the window background.

/C Changes existing textbox.

/D={thickMult [, shadowThick [, haloThick]]}
thickMult multiplies the normal frame thickness of a text-box. The thickness may be set using just */D=thickMult*.

shadowThick, if present, overrides Igor's normal shadow thickness. It is in units of fractional points.

haloThick governs the annotation's halo thickness (a surrounding band of the annotation's background color), which can be -1 to 10 points wide.

The default *haloThick* value is -1, which preserves the behavior of previous versions of Igor where the halo of all annotations was set by the global variable *root:V_TBBufZone*. Any negative value of *haloThick* (-0.5, for example) will be overridden by *V_TBBufZone* if it exists, otherwise the absolute value of *haloThick* will be used. A zero or positive value overrides *V_TBBufZone*.

Any of the parameters may be missing. To set *haloThick* to 0 without changing other parameters, use */D={ , , 0 }*.

/E[=exterior] */E* or */E=1* forces textbox (or legend) to be exterior to graph (provided *anchorCode* is not MC) and pushes the graph margins away from the anchor edge(s). */E=2* also forces exterior mode but does not push the margins.

/E=0 returns it to the default (an "interior textbox" which can be anywhere in the graph window).

/F=frame

- frame=0:* No frame.
- frame=1:* Underline frame.
- frame=2:* Box frame (default).

/G=(r,g,b) Sets color of the text in the tag. *r*, *g*, and *b* specify the amount of red, green, and blue as an integer from 0 to 65535.

/H=legendSymbolWidth
legendSymbolWidth sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.

/K Kills existing textbox.

/LS= linespace Specifies a tweak to the normal line spacing where *linespace* is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.

<i>/M[=saMeSize]</i>	<p><i>/M</i> or <i>/M=1</i> specifies that legend markers should be the same size as the marker in the graph.</p> <p><i>/M=0</i> turns same-size mode off so that the size of the marker in the legend is based on text size.</p>
<i>/N=name</i>	Specifies the name of the textbox to change or create.
<i>/O=rot</i>	<p>Rotates the text by <i>rot</i> degrees counterclockwise (valid rotations are -90, 0, 90, 180, or 270). 0 is normal horizontal left-to-right text.</p> <p>90 is vertical bottom-to-top text, etc.</p>
<i>/R=newName</i>	Renames the textbox.
<i>/S=style</i>	<p><i>style=0</i>: Single frame.</p> <p><i>style=1</i>: Double frame.</p> <p><i>style=2</i>: Triple frame.</p> <p><i>style=3</i>: Shadow frame.</p>
<i>/T=tabSpec</i>	<i>tabSpec</i> is a single number in points, such as <i>/T=72</i> , for evenly spaced tabs or a list of tab stops in points such as <i>/T={50, 150, 225}</i> .
<i>/V=vis</i>	<p><i>vis=0</i>: Invisible annotation; not selectable. The annotation is still listed in AnnotationList.</p> <p><i>vis=1</i>: Visible annotation.</p>
<i>/W=winName</i>	<p>Operates in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.</p> <p>When identifying a subwindow with <i>winName</i>, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.</p>
<i>/X=xOffset</i>	<p>For interior textboxes <i>xOffset</i> is the distance from anchor to textbox as a percentage of the plot area width.</p> <p>For exterior textboxes <i>xOffset</i> is the distance from anchor to textbox as a percentage of the graph window width. See <i>/E</i> and <i>/A</i>.</p>
<i>/Y=yOffset</i>	<i>yOffset</i> is the distance from anchor to textbox as a percentage of the plot area height (interior textboxes) or graph window height (exterior textboxes). See <i>/E</i> and <i>/A</i> .
<i>/Z=freeZe</i>	<p><i>freeZe=1</i>: Freezes annotation position (you can't move it with the mouse) in graphs but not in page layouts.</p> <p><i>freeZe=0</i>: Unfreezes it. Annotations are always unfrozen in page layouts.</p>

Details

Use the optional */W=winName* flag to specify a specific graph or layout window. When used on the command line or in a Macro, Proc, or Window procedure, */W* must precede all other flags.

If the */C* flag is used, it must be the first flag in the command (except that it may follow an initial */W*) and must be followed immediately by the */N=name* flag.

If the */K* flag is used, it must be the first flag in the command (or follow an initial */W*) and must be followed immediately by the */N=name* flag with no further flags or parameters.

textStr is optional. If missing, the textbox text is unchanged. This allows changes to the textbox to be made through the flags without changing the text.

A textbox can have at most 100 lines.

textStr can contain the following escape codes which affect subsequent characters in string. See **Notes about Backslashes**.

The characters "<??>" in a textbox indicate that you specified an invalid escape code or used a font that is not available.

The escape codes are:

<i>\[<digit></i>	Store info variable.
<i>\]<digit></i>	Recall info variable.
<i>\B</i>	Use subscript (in smaller type above baseline).
<i>\F'fontName'</i>	Use specified font (e.g., <i>\F 'Helvetica'</i>).

<code>\fdd</code>	<p><i>dd</i> is a binary coded number with each bit controlling one aspect of the column's font style as follows:</p> <ul style="list-style-type: none"> bit 0: Bold bit 1: Italic bit 2: Underline bit 3: Outline (<i>Macintosh only</i>) bit 4: Shadow (<i>Macintosh only</i>) <p>For example, bold underline is $2^0 + 2^2 = 1 + 4 = 5$. See Setting Bit Parameters on page IV-11 for details about bit settings.</p>
<code>\JR</code>	Right align text.
<code>\JC</code>	Center align text.
<code>\JL</code>	Left align text.
<code>\K(r,g,b)</code>	Use specified color for text. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535.
<code>\k(r,g,b)</code>	Use specified color for marker stroke (line color). <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Use before <code>\Wtdd</code> to change marker stroke color from the default of black (0,0,0).
<code>\Ldtss</code>	Draws a line from x position specified in text info variable <i>d</i> to the current x position. Uses current text color. Thickness is encoded by digit <i>t</i> with values of 4,5,6 and 7 giving 0.25, 0.5, 1.0 and 1.5 pt. Line style is specified by 2 digit number <i>ss</i> .
<code>\M</code>	Use normal (main) script (reverts to main line and size).
<code>\S</code>	Use superscript (in smaller type below baseline).
<code>\Wtdd</code>	Draws a marker symbol using current font size and color. Line thickness is coded by digit <i>t</i> with 4, 5 and 6 giving 0.25, 0.5 and 1.0 pt. Marker symbol number is specified by 2 digit number <i>dd</i> .
<code>\X<digit></code>	Recall X position.
<code>\x+dd</code>	Moves X position right by $2*dd$ percent of the current font max width.
<code>\x-dd</code>	Moves X position left by $2*dd$ percent of the current font max width.
<code>\Y<digit></code>	Recall Y position.
<code>\y+dd</code>	Moves Y position up by $2*dd$ percent of the current font height.
<code>\y-dd</code>	Moves Y position down by $2*dd$ percent of the current font height.
<code>\Znn</code>	Use font size <i>nn</i> (<i>nn</i> must be exactly two digits).
<code>\Zrnnn</code>	<i>nnn</i> is a 3 digit percentage by which to change the current font size. (<i>nnn</i> must be exactly three digits).

textStr can also contain escape codes to manipulate text info variables (see **About Text Info Variables** on page III-61).

textStr can also contain the following escape code which inserts the symbol used to display the named wave:

`\s(traceName)`

`\s` is mainly used in Legends, where legend symbols are automatically created and removed, but it can also be used in Tags, Textboxes, and axis labels where the symbol is updated, but not automatically added or removed. See **Freezing the Legend Text** on page III-50.

textStr can also contain an escape code which inserts dynamically evaluated text:

`\{dynText}`

Dynamically evaluated text (*dynText*) may contain numeric and string expressions. Igor automatically reevaluates *dynText* when a numeric or string variable or wave referenced in *dynText* changes.

Note: When used in *dynText* expressions, user-defined numeric and string variables in macros or functions must be declared as global variables for the expression to evaluate correctly.

dynText can take two forms, an easy one for a single numeric expression and a more complex form that provides precise control over the formatting of the result.

The easy form is:

`\{numeric-expression}`

This evaluates the expression and prints with generic ("%g") formatting.

The full form is:

```
\{formatStr, list-of-numeric-or-string-expressions}
```

formatStr and *list-of-numeric-or-string-expressions* are treated as for **printf**.

As an aid in typing the expressions, Igor considers carriage returns between the braces to be equivalent to spaces. Rather than typing (in the Add Annotation dialog):

```
\{"twice K0 is %g, and today is %s",2*K0,date()}
```

you can type:

```
\{
    "twice K0 is %g, and today is %s",
    2*K0,
    date()
}
```

These carriage returns can be typed directly in the Add Annotations dialog, or be typed as “\r” in a macro, function or the command line.

Notes about Backslashes

Each backslash character in *textStr* should be preceded with another backslash when it appears in a macro, function or on the command line. This is because backslash is itself a special escape character for strings. Future versions of Igor may require this double-backslash syntax; currently Igor accepts either the single or double backslash as synonyms for inserting a single backslash into a string.

For example:

```
String myStr = "\\OK"
Print myStr
```

Prints the following in the history area:

```
\OK
```

myStr contains a *single* backslash character. See **Escape Characters in Strings** on page IV-13 for more about the backslash character. This behavior affects how escape sequences in *textStr* should be written:

```
TextBox/C/N=text0 "\Z14Bigger"      // no: Future Igors may see "Z14Bigger"
TextBox/C/N=text0 "\\Z14Bigger"     // yes
TextBox/C/N=text0 "first line\rsecond line" // carriage return uses one \
```

Since \r (carriage return) is not a textbox escape sequence, only one backslash is needed.

You can see how backslashes in *textStr* should be entered by using the Add Annotation dialog and observing the command it creates. You will observe many double backslash sequences. Single backslash sequences were used by Igor 1.2, which Igor Pro currently accepts for backward compatibility reasons.

Examples

```
TextBox/C/N=t1/X=25/Y=50
```

moves the textbox named t1 to the location defined by X=25 and Y=50.

```
TextBox/C/N=t1 "New Text"
```

changes the text for t1.

See Also

See **About Text Info Variables** on page III-61 for *textStr* escape codes that manipulate text info variables. The **AppendText** operation. See the discussion above in **Notes about Backslashes and Escape Characters in Strings** on page IV-13 for still more about the backslash character. See the **printf** operation for formatting codes used in *formatStr*.

TextFile

TextFile(pathName, index [, creatorStr])

The TextFile function returns a string containing the name of the *index*th TEXT file from the folder specified by *pathName*.

On Windows, Igor considers files with “.txt” extensions to be of type TEXT.

Details

TextFile returns the null string ("") if there is no such file.

pathName is the name of an Igor symbolic path; it is *not* a string.

ThreadGroupCreate

index starts from zero.

creatorStr is an optional string argument containing four characters such as "IGR0". Only files of the specified Macintosh creator code are indexed. Set *creatorStr* to "?????" to index all text files (or omit the argument altogether). This argument is ignored on Windows systems.

The order of files in a folder is determined by the operating system.

Examples

You can use `TextFile` in a procedure to sequence through each TEXT file in a folder, put the name of the text file into a string variable, and use this string variable as a parameter to the **LoadWave** or **Open** operations:

```
Function/S PrintFirstLineOfTextFiles(pathName)
    String pathName                // Name of an Igor symbolic path.
    Variable refNum, index
    String str, fileName
    index = 0
    do
        fileName = TextFile($pathName, index)
        if (strlen(fileName) == 0)
            break                // No more files
        endif
        Open/R/P=$pathName refNum as fileName
        FReadLine refNum, str      // Read first line including CR/LF
        Print fileName + ":" + str // Print file name and first line
        Close refNum
        index += 1                // Next file
    while (1)
End
```

See Also

See the **IndexedFile** function, which is similar to `TextFile` but works on files of any type, and also **IndexedDir**. Also see the **LoadWave** and **Open** the operations.

ThreadGroupCreate

ThreadGroupCreate(*nt*)

The `ThreadGroupCreate` function creates a thread group containing *nt* threads and returns a thread ID number. Use the number of computer processors for *nt* when trying to improve computation speed using parallel threads. A background worker might use just one thread regardless of the number of processors.

See Also

ThreadSafe Functions on page IV-66 and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadGroupGetDF

ThreadGroupGetDF(*tgID*, *waitms*)

The `ThreadGroupGetDF` string function retrieves a data folder from a thread group input queue when called from a preemptive thread or, when called from the main thread, retrieves data folder of data from the thread group's output queue. Returns the data folder name or "" if none found owing to timeout. *tgID* is the thread group ID returned by **ThreadGroupCreate**, *waitms* is milliseconds to wait. When called from a preemptive thread, *tgID* may be zero.

Considerations for milliseconds to wait are the same as those for **ThreadGroupWait**.

See Also

ThreadSafe Functions on page IV-66 and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadGroupPutDF

ThreadGroupPutDF *tgID*, *datafolder*

The `ThreadGroupPutDF` operation posts data to a preemptive thread group.

Parameters

tgID is thread group ID returned by **ThreadGroupCreate**, *datafolder* is the data folder you wish to send to the thread group.

datafolder can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

When called from the main thread, **ThreadGroupPutDF** removes *datafolder* from main and posts to the input queue of the thread group specified by *tgID*. When called from a preemptive thread, use 0 for *tgID* and the data folder will be posted to the output queue of thread group to which thread belongs. Input and output data folders may be retrieved from the queues by calling the string function **ThreadGroupGetDF**.

Warning: Take care not to use any stale WAVE, NVAR, or SVAR variables that might contain references to objects in the data folder. Use **WAVEClear** on all WAVE reference variables that might contain references to waves that are in the data folder being posted before calling **ThreadGroupPutDF**. An error will occur if any waves in the data folder are in use or referenced in a WAVE variable.

From the standpoint of the source thread, **ThreadGroupPutDF** is conceptually similar to **KillDataFolder** and, like **KillDataFolder**, if the current data folder is within *datafolder*, the current data folder is set to the parent of *datafolder*. You can not pass `root :` as *datafolder*.

See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadGroupRelease

ThreadGroupRelease(*tgID*)

The **ThreadGroupRelease** function releases thread group (and *tgID* is no longer valid). *tgID* is the thread group ID returned by **ThreadGroupCreate**.

If threads are still running, they are killed. An attempt is made to safely stop running threads but, if they continue to run, they will be force quit.

ThreadGroupRelease returns zero if successful, -1 if an error occurred (probably invalid *tgID*), or -2 if a force quit was needed. In the latter case, you should restart Igor Pro.

Any data folders remaining in the group's input or output queues will be discarded.

See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadGroupWait

ThreadGroupWait(*tgID*, *waitms*)

The **ThreadGroupWait** function returns index+1 of the first thread found still running after *waitms* or returns zero if all are done. *tgID* is the thread group ID returned by **ThreadGroupCreate** and *waitms* is milliseconds to wait.

If any of the threads of the group encountered a runtime error, the first such error will be reported now.

Use zero for milliseconds to wait to just test or provide a large value to cause the main thread to sleep until the threads are finished. You can use inf to wait forever (or until a user abort.) If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don't return in time.

See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadProcessorCount

ThreadProcessorCount

The **ThreadProcessorCount** function returns the number of processors in your computer. For example, on a Macintosh Core Duo, it would return 2.

ThreadReturnValue

ThreadReturnValue(*tgID*, *index*)

The ThreadReturnValue function returns the value that the specified thread function returned when it exited. Returns NAN if thread is still running. *tgID* is the thread group ID returned by **ThreadGroupCreate** and *index* is the thread number.

See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadSafe

ThreadSafe Function *funcName*()

The ThreadSafe keyword declaration specifies that a user function can be used for preemptive multitasking background tasks on multiprocessor computer systems.

A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads. Such functions are generally limited to numeric or utility functions. Functions that access windows are not ThreadSafe. To determine if an operation is ThreadSafe, use the Command Help tab of the Help Browser and choose ThreadSafe from the pop-up menu.

ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. Non-ThreadSafe functions can call ThreadSafe functions.

See Also

ThreadSafe Functions on page IV-66 and **ThreadSafe Functions and Multitasking** on page IV-214.

ThreadStart

ThreadStart *tgID*, *index*, *WorkerFunc*(*param1*, *param2*,...)

The ThreadStart operation starts the specified function running in a preemptive thread.

Parameters

tgID is thread group ID returned by **ThreadGroupCreate**, *index* is the desired thread of the group to set up to execute the specified ThreadSafe *WorkerFunc*.

Details

Your function starts running immediately.

You may not use any pass-by-reference parameters. Any waves you pass are then accessible to both the main thread and to your preemptive thread. Such waves are then marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.

The function must be defined as ThreadSafe and be numeric, either real or complex. The return value can be obtained after the function finishes by calling ThreadReturnValue.

See Also

The **ThreadGroupCreate** and **ThreadReturnValue** functions; **ThreadSafe Functions** on page IV-66, and **ThreadSafe Functions and Multitasking** on page IV-214.

ticks

ticks

The ticks function returns the number of ticks (approximately 1/60 second) elapsed since the operating system was initialized.

See Also

The **stopMSTimer** function.

Tile

Tile [*flags*] [*objectName* [, *objectName*]...]

The Tile operation tiles the specified objects in the top page layout.

Parameters

objectName is the name of a graph, table, picture or annotation object in the top page layout.

Flags

/A=(<i>rows,cols</i>)	Specifies number of rows/columns in which to tile objects.
/G= <i>grout</i>	Specifies grout, the spacing between window tiles, in prevailing coordinates (points unless preceded by /I, /M or /R).
/I	Specifies coordinates in inches.
/M	Specifies coordinates in centimeters.
/O= <i>objTypes</i>	Adds objects of type(s) specified by bitwise mask to list of objects to be tiled: 1 (bit 0): Tile graphs. 2 (bit 1): Tile tables. 8 (bit 3): Tile pictures. 32 (bit 5): Tile textboxes. See Setting Bit Parameters on page IV-11 for details about bit settings.
/R	Specifies coordinates measured in percent of the printable page.
/S	Adds selected objects to objects to be tiled.
/W=(<i>left,top,right,bottom</i>)	Specifies page layout area in which to tile objects. Coordinates are in points unless /I, /M or /R are specified before /W.

Details

If /A=(*rows,cols*) is not used, Tile uses an appropriate number of rows and columns. If /A=(*rows,cols*) is used, objects are tiled in a grid of that many rows and columns. If *rows* or *cols* is zero, it substitutes an appropriate number for the zero parameter.

Objects to be tiled are determined by the /S and /O=*objTypes* flags and by any *objectNames*.

If no /S or /O flags are present and there are no *objectNames*, then all objects in the layout are tiled.

Otherwise the objects to be tiled are determined as follows:

- All *objectNames* are tiled.
- If the /S flag is present, the selected objects (if any) are also tiled.
- If the /O=*objTypes* flag is present then any objects specified by *objTypes* are also tiled. *objTypes* is a bitwise mask, so /O=3 tiles both graphs and tables.

See Also

The **Stack** operation.

TileWindows

TileWindows [*flags*] [*windowName* [, *windowName*]...]

The TileWindows operation tiles the specified windows on the desktop (*Macintosh*) or in the Igor frame window (*Windows*).

Flags

/A=(<i>rows,cols</i>)	Specifies number of rows/columns in which to tile windows.
/C	Adds the command window to the windows to be tiled.
/G= <i>grout</i>	Specifies grout, the spacing between tiles, in prevailing units (points unless /I or /M are used).
/I	Specifies coordinates in inches.
/M	Specifies coordinates in centimeters.
/O= <i>objTypes</i>	Adds windows of types specified by <i>objTypes</i> to windows to be tiled. <i>objTypes</i> is a bitwise mask where: bit 0: Graphs.

time

- bit 1: Tables.
- bit 2: Page layouts.
- bit 4: Notebooks.
- bit 6: Control panels.
- bit 7: Procedure windows.
- bit 9: Help windows.
- bit 12: XOP target windows (e.g., surface plots).

Other bits should always be zero. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

/P Adds the main procedure window to the windows to be tiled.

/R Specifies coordinates measured as % of tiling rectangle.

/W=(left,top,right,bottom)

Specifies tiling rectangle on the screen. Coordinates are in points unless /I, /M, or /R are specified before /W.

Details

The windows to be tiled are determined by the /C, /P, and /O=*objTypes* flags and by the *windowNames*. If no /C, /P or /O flags are present and there is no *windowNames* then all windows are tiled.

Otherwise the windows to be tiled are determined as follows:

- All named windows are tiled.
- If the /C flag is present, the command window is also tiled.
- If the /P flag is present, the procedure window is also tiled.
- If the /O=*objTypes* flag is present, any windows specified by *objTypes* are also tiled.

Examples

To tile all the procedure windows, including the main one, use:

```
TileWindows/P/O=128          // 2^7=128
```

See Also

The **StackWindows** operation.

time

time()

The time function returns a string containing the current time. The empty parentheses are required.

See Also

The **date**, **date2secs** and **DateTime** functions.

TitleBox

TitleBox [/Z] *ctrlName* [*key* [= *value*]][, *key* [= *value*]]...

The TitleBox operation creates the named title box in the target window.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the TitleBox control to be created or changed.

key is one of the following parameters:

anchor=*hv* Specifies the anchor mode using a two letter code, *hv*. *h* may be L, M, or R for left, middle, and right. *v* may be T, C, or B for top, center and bottom. Default is LT.

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of **default**, **native**, or **os9**.

platform can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

<code>disable=<i>d</i></code>	Sets user editability of the control. <i>d</i> =0: Normal. <i>d</i> =1: Hide. <i>d</i> =2: Draw in gray state.
<code>fColor=(<i>r,g,b</i>)</code>	Sets color of the titlebox. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535
<code>font="font<i>Name</i>"</code>	Sets the font used for the control, e.g., <code>font="Helvetica"</code> .
<code>frame=<i>f</i></code>	Sets frame style. <i>f</i> =0: No frame. <i>f</i> =1: Default (same as <i>f</i> =3). <i>f</i> =2: Simple box. <i>f</i> =3: 3D sunken frame. <i>f</i> =4: 3D raised frame. <i>f</i> =5: Text well.
<code>fsize=<i>s</i></code>	Sets font size.
<code>fstyle=<i>fs</i></code>	<i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows: bit 0: Bold. bit 1: Italic. bit 2: Underline. bit 3: Outline (<i>Macintosh only</i>). bit 4: Shadow (<i>Macintosh only</i>). See Setting Bit Parameters on page IV-11 for details about bit settings.
<code>labelBack=(<i>r,g,b</i>)</code> or 0	Sets background color for title box. <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. If not set (or <code>labelBack=0</code>), then background is transparent (not erased).
<code>pos={<i>left,top</i>}</code>	Sets the location of the top left corner in pixels.
<code>size={<i>w,h</i>}</code>	Set the width and height in pixels.
<code>title=<i>titleStr</i></code>	Sets text of title box to <i>titleStr</i> . Limited to 63 characters.
<code>variable= <i>svar</i></code>	Specifies an optional global string variable from which to get the TitleBox text.
<code>win=<i>winName</i></code>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The text can come from either the `title=titleStr` or `variable=svar` method. Whichever is used last is the current method. The maximum length of text with the `title=titleStr` method is 63 chars while the `variable=svar` method has no limit.

The text can contain escape codes to create fancy results with multiple lines, font changes etc. The escape codes are essentially the same as those for the TextBox operation. The easiest way to generate fancy text is to create a dummy TextBox, set up the text as desired and then click the To Cmd Line button followed by editing of the command line.

The TitleBox automatically resizes itself relative to the anchor point on the rectangle that encloses the text. Therefore you can specify a size of 0,0 along with a pos value to place the anchor point at the pos value.

TitleBoxes can be used not only for titles but also as status or results readout areas, especially in conjunction with the `variable= svar` mode.

Examples

```
NewPanel /W=(94,72,459,294)
DrawLine 150,32,150,140
DrawLine 70,100,213,100           // draw crossing lines at 150,100
```

ToCommandLine

```
// illustrate a default box
TitleBox tbl,title="A title box\rwith 2 lines",pos={150,100}

// Move center to 150,100
TitleBox tbl,pos={150,100},size={0,0},anchor=MC
// Set background color and therefore opaque mode
TitleBox tbl,labelBack=(55000,55000,65000)

// Now a few frame styles. Run these one at a time
TitleBox tbl,frame= 0          // no frame
TitleBox tbl,frame= 2          // plain frame
TitleBox tbl,frame= 3          // 3D sunken
TitleBox tbl,frame= 4          // 3D raised
TitleBox tbl,frame= 5          // text well

// Now some fancy text...
TitleBox tbl,frame= 1          // back to default (3D raised)
TitleBox tbl,title= "\Z18\[020 log\B10\M|[1 + 2K(jwt) + (jwt)\S2\M]|\S-1"

// Create a string variable and hook up to the TitleBox
String sl= "text from a string variable"
TitleBox tbl,variable=sl

// Change string variable contents & note automatic update of TitleBox
sl= "something new"
```

See Also

ToCommandLine

ToCommandLine *commandsStr*

The ToCommandLine operation sends command text to the command line without executing the command(s).

The intended usage is for user-created panel windows with “To Cmd Line” buttons that are mimicking built-in Igor dialogs. You’ll usually want to use Execute, instead.

Parameters

commandsStr The text of one or more commands.

Details

To send more than one line of commands, separate the commands with “\r” characters.

Note: ToCommandLine does not work when typed on the command line; use it only in a Macro, Proc, or Function.

Examples

```
Macro CmdPanel()
  PauseUpdate; Silent 1
  NewPanel /W=(150,50,430,229)
  Button toCmdLine,pos={39,148},size={103,20},title="To Cmd Line"
  Button toCmdLine,proc=ToCmdLineButtonProc
End

Function ToCmdLineButtonProc(ctrlName) : ButtonControl
  String ctrlName

  String cmd="MyFunction(xin,yin,\"yResult\")" // line 1: generate results
  cmd += "\rDisplay yOutput vs wx as \"results\"" // line 2: display results
  ToCommandLine cmd
End
```

See Also

The Execute and DoIgorMenu operations.

ToolsGrid

ToolsGrid [/W=*winName*] **keyword** = **value** [, **keyword** = **value** ...]

The ToolsGrid operation controls the grid you can use for laying out draw or control objects.

Parameters

ToolsGrid can accept multiple *keyword* = *value* parameters on one line.

<code>snap=<i>n</i></code>	Turns snap to grid on ($n=1$) or off ($n=0$).
<code>visible=<i>n</i></code>	Turns on grid visibility ($n=1$) or hides it ($n=0$).
<code>grid=(<i>xy0,dxy,ndiv</i>)</code>	Defines both X and Y grids where <i>ndiv</i> is the number of subdivisions between major grid lines and <i>xy0</i> and <i>dxy</i> define the origin and spacing. Units are in points.
<code>gridx=(<i>x0,dx,ndiv</i>)</code>	Defines the X grid where <i>ndiv</i> is the number of subdivisions between major grid lines and <i>x0</i> and <i>dx</i> define the origin and spacing. Units are in points.
<code>gridy=(<i>y0,dy,ndiv</i>)</code>	Defines the Y grid where <i>ndiv</i> is the number of subdivisions between major grid lines and <i>y0</i> and <i>dy</i> define the origin and spacing. Units are in points.

Flags

<code>/W=<i>winName</i></code>	Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
--------------------------------	---

Details

The default grid is 1 inch with 8 subdivisions. The grid is visible only in draw or selector mode and appears in front of the currently active draw layer.

TraceFromPixel

TraceFromPixel(*xpixel, ypixel, optionsString*)

The TraceFromPixel function returns a string based on an attempt to hit test the provided X and Y coordinates. Used to determine if the mouse was clicked on a trace in a graph.

When a trace is found, TraceFromPixel returns a string containing the following **KEY:value;** pairs:

TRACE: *tracename*

HITPOINT: *pnt*

tracename will be quoted if necessary and may contain instance notation. *pnt* is the point number index into the trace's wave when the hit was detected. If a trace is not found near the coordinate point, a zero length string is returned.

Parameters

xpixel and *ypixel* are the X and Y pixel coordinates.

optionsString can contain the following:

WINDOW: *winName*;

PREF: *traceName*;

ONLY: *traceName*;

Use the WINDOW option to hit test in a graph other than the top graph. Use the ONLY option to search only for a special target trace. If the PREF option is used then the search will start with the specified trace but if no hit is detected, it will go on to the others.

When identifying a subwindow with **WINDOW:** *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

The **NumberByKey**, **StringByKey**, **AxisValFromPixel**, and **PixelFromAxisVal** functions.

ModifyGraph (traces) and **Instance Notation** on page IV-16 for discussions of trace names and instance notation.

TraceInfo

TraceInfo(*graphNameStr, ywavenameStr, instance*)

The TraceInfo function returns a string containing a semicolon-separated list of information about the trace in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

yWaveNameStr is either the name of a wave containing data displayed as a trace in the named graph, or a trace name (wave name with “#n” appended to distinguish the nth image of the wave in the graph). You might get a trace name from the **TraceNameList** function.

If *yWaveNameStr* contains a wave name, *instance* identifies which trace of *yWaveNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a given wave displayed in a graph. Set *instance* to 1 for information about the second trace of the wave named by *yWaveNameStr*, etc. If *yWaveNameStr* is “”, then information is returned on the *instanceth* trace in the graph.

If *yWaveNameStr* is a trace name, and *instance* is zero, the instance is extracted from *yWaveNameStr*. If *instance* is greater than zero, the wave name is extracted from *yWaveNameStr*, and information is returned concerning the *instanceth* instance of the wave.

Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

Keyword	Information Following Keyword
AXISFLAGS	Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.
AXISZ	Z value of a contour level trace or NaN if the trace is not a contour trace.
RECREATION	List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: <i>keyword(x)=modifyParameters;</i>
XAXIS	X axis name.
XRANGE	Point subrange of the trace’s X data wave in “[startPoint, endPoint : increment]” format. Note: Unlike the actual syntax of a trace subrange specification where increment is preceded by a semicolon character, here it is preceded by a colon character to preserve the notion that semicolon is what separates the keyword-value groups. If the entire X wave is displayed (the usual case), the XRANGE value is “[*]”. If an X wave is not used to display the trace, then the XRANGE value is “”.
XWAVE	X wave name if any, else blank.
XWAVEDF	Full path to the data folder containing the X wave or blank if no X wave.
YAXIS	Y axis name.
YRANGE	Point subrange of the trace’s Y data wave or “[*]”.

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyGraph ”, replace the “x” with the name of a trace (“data#1” for instance) and then **Execute** the resultant string as a command.

Note: The syntax of any subrange specifications in the RECREATION information are modified in the same way as for XRANGE and YRANGE. Currently only the zColor, zmrkSize, and zmrkNum keywords might have a subrange specification.

Examples

This example shows how to extract a string value from the keyword-value list returned by TraceInfo:

```
String yAxisName= StringByKey("YAXIS", TraceInfo("", "", 0))
```

This example shows how to extract a subrange and put the semicolon back:

```
String yRange= StringByKey("YRANGE", TraceInfo("", "", 0))
Print yRange           // prints "[30,40:2]"
yRange= ReplaceString(":", yRange, ";")
Print yRange           // prints "[30,40;2]"
```

The next example shows the trace information for the second instance of the wave "data" (which has an instance number of 1) displayed in the top graph:

```
Make/O data=x;Display/L/T data,data          // two instances of data: 0 and 1
Print TraceInfo("", "data", 1)[0,64]         // error if you try to print all
Print TraceInfo("", "data", 1)[65,128]
```

Prints the following in the history area:

```
XWAVE:;YAXIS:left;XAXIS:top;AXISFLAGS:/T;AXISZ:NAN(255);XWAVEDF:;
RECREATION:zColor(x)=0;zmrkSize(x)=0;zmrkNum(x)=0;textMarker(x)=
```

Following is a function that returns the marker code from the given instance of a named wave in the top graph. This example uses the convenient GetNumFromModifyStr() function provided by the #include <Readback ModifyStr> procedures, which are useful for parsing strings returned by TraceInfo.

```
#include <Readback ModifyStr>
Function MarkerOfWave(wv,instance)
    Wave wv
    Variable instance

    Variable marker
    String info = TraceInfo("", NameOfWave(wv), instance)
    marker = GetNumFromModifyStr(info, "marker", "", 0)
    return marker
End
```

See Also

The **Execute** operation.

TraceNameList

TraceNameList(*graphNameStr*, *separatorStr*, *optionsFlag*)

The TraceNameList function returns a string containing a list of trace names in the graph window or subwindow identified by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single character such as "," or ";" to separate the names.

Details

The bits of *optionsFlag* have the following meanings:

Bit Number	Bit Value	Meaning
0	1	Include normal graph traces.
1	2	Include contour traces.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

A trace name is defined as the name of the Y wave that defines the trace with an optional #ddd suffix that distinguishes between two or more traces that have the same wave name. Since the trace name has to be parsed, it is quoted if necessary.

Commands that take a trace name as a parameter or in a keyword can use a string containing a trace name with the \$ operator to specify traceName. For instance, to change the display mode of a wave, you might use

```
ModifyGraph mode(myWave#1)=3
but
String myTraceName="myWave#1"
ModifyGraph mode($myTraceName)=3
will also work.
```

Examples

```
Make jack,'jack # 2';Display jack,jack,'jack # 2','jack # 2'
Print TraceNameList("", ";", 1)
```

TraceNameToWaveRef

prints jack;jack#1;'jack # 2';jack # 2'#1;

For a description of traces: **ModifyGraph**. For a discussion of contour traces: **All About Contour Traces** on page II-306.

For commands referencing other waves in a graph: **ImageNameList**, **ImageNameToWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

ModifyGraph (traces) and **Instance Notation** on page IV-16 for discussions of trace names and instance notation.

TraceNameToWaveRef

TraceNameToWaveRef(*graphNameStr*, *traceNameStr*)

The **TraceNameToWaveRef** function returns a wave reference to the Y wave corresponding to the given trace in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The trace is identified by the string in *traceNameStr*, which could be a string determined using **TraceNameList**. Note that the same trace name can refer to different waves in different graphs.

Use **Instance Notation** (see page IV-16) to choose from traces in a graph that represent waves of the same name. For example, if *traceNameStr* is "myWave#2", it refers to the third instance of wave "myWave" in the graph ("myWave#0" or just "myWave" is the first instance).

Triangulate3d

Triangulate3d [/OUT=*format*] *srcWave*

The **Triangulate3d** operation creates a Delaunay "triangulation" of a 3D scatter wave. The output is a list of tetrahedra that completely span the convex volume defined by *srcWave*. **Triangulate3d** can also generate the triangulation needed for performing 3D interpolation for the same domain. Normally *srcWave* is a triplet wave (a 2D wave of 3 columns), but can use any 2D wave that has more than 3 columns (the operation ignores all but the first 3 columns).

Flags

/OUT=*format* Specifies how to save the output triangulation data.

format=1: Default; saves the triangulation result in the wave M_3DVertexList, which contains in each row, indices to rows in *srcWave* that describe the X, Y, Z coordinates of a single tetrahedral vertex. Each tetrahedron is described by one row in M_3DVertexList.

format=2: Saves the triangulation result in the wave M_TetraPath, which is a triplet path wave describing the tetrahedra edges. For each tetrahedron, there are four rows (triangles) separated by row of NaNs. The total number of rows in M_TetraPath is 20 times the number of tetrahedra in the triangulation.

format=4: Saves a wave containing internal diagnostic information generated during the triangulation process.

Details

Triangulate3d implements Watson's algorithm for tetrahedralization of a set of points in three dimensions. It starts by creating a very large tetrahedron which inscribes all the data points followed by a sequential insertion of one datum at a time. With each new datum the algorithm finds the tetrahedron in which the datum falls. It then proceeds to subdivide the tetrahedron so that the datum becomes a vertex of new tetrahedra.

Watson's algorithm suffers from two known problems. First, it may have numerical instabilities if resulting tetrahedra are too thin. The second problem involves memory allocations, which may be insufficient for some pathological spatial distributions of data points. Triangulate3d reports both problems in the history window.

Examples

```
Make/O/N=(10,3) ddd=gnoise(5)          // create random 10 points in space
Triangulate3d/out=2 ddd
// now display the triangulation in Gizmo:
Window Gizmo0() : GizmoPlot
  PauseUpdate; Silent 1
  if(exists("NewGizmo")!=4)
    DoAlert 0, "Gizmo XOP must be installed"
    return
  endif
  NewGizmo/N=Gizmo0 /W=(309,44,642,373)
  ModifyGizmo startRecMacro
  ModifyGizmo scalingMode=2
  AppendToGizmo Scatter=root:ddd,name=scatter0
  ModifyGizmo ModifyObject=scatter0 property={ scatterColorType,0}
  ModifyGizmo ModifyObject=scatter0 property={ Shape,2}
  ModifyGizmo ModifyObject=scatter0 property={ size,0.2}
  ModifyGizmo ModifyObject=scatter0 property={ color,0,0,0,1}
  AppendToGizmo Path=root:M_TetraPath,name=path0
  ModifyGizmo ModifyObject=path0 property={ pathColor,0,0,1,1}
  ModifyGizmo setDisplayList=0, object=scatter0
  ModifyGizmo setDisplayList=1, object=path0
  ModifyGizmo autoscaling=1
  ModifyGizmo compile
  ModifyGizmo endRecMacro
End
```

try-catch-endtry

```
try
  <possible abort code>
catch
  <code to handle abort>
endtry
```

A try-catch-endtry flow control statement provides a means for catching and responding to abort conditions in user functions.

When code executes in the try-catch area, any programmatic aborts will immediately jump to code within the catch-endtry area rather than jumping to the end of the user function. Normal flow (no aborts) will skip all code within the catch-endtry area.

UniqueName

Details

During execution of code in the catch-endtry area, user aborts are suppressed. This means that when the user attempts to abort procedure execution by holding down the appropriate abort key combination, it will not abort the catch code itself.

Whenever an abort occurs, information about the cause of the abort is returned via the following variable:

```
V_AbortCode = -4:   Abort triggered by AbortOnRTE.
              -3:   Abort caused by Abort operation.
              -2:   Stack overflow abort.
              -1:   User abort.
              ≥1:   Abort triggered by AbortOnValue.
```

See Also

Flow Control for Aborts on page IV-37 and **try-catch-endtry Flow Control** on page IV-37 for further details.

The **AbortOnRTE** and **AbortOnValue** keywords, and the **Abort** operation.

UniqueName

UniqueName(*baseName*, *objectType*, *startSuffix* [, *windowNameStr*])

The UniqueName function returns the concatenation of *baseName* and a number such that the result is not in conflict with any other object name.

windowNameStr is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

Details

baseName should be an unquoted name, such as you might receive from the user via a dialog or control panel.

objectType is one of the following:

- | | | | |
|---|---|----|---|
| 1 | Wave. | 9 | Control panel window. |
| 2 | Reserved. | 10 | Notebook window. |
| 3 | Numeric variable. | 11 | Data folder. |
| 4 | String variable. | 12 | Symbolic path. |
| 5 | XOP target window (e.g., surface plot). | 13 | Picture. |
| 6 | Graph window. | 14 | Annotation in the named or topmost graph or layout. |
| 7 | Table window. | 15 | Control in the named or topmost graph or panel. |
| 8 | Layout window. | 16 | Notebook action character in the named or topmost notebook. |

startSuffix is the number used as a starting point when generating the numeric suffix that makes the name unique. Normally you should pass zero for *startSuffix*. If you know that names of the form *base0* through *baseN* are in use, you can make UniqueName run a bit faster by passing *N+1* as the *startSuffix*.

The *windowNameStr* argument is used only with *objectTypes* 14, 15, and 16. The returned name is unique only to the window (other windows might have objects with the same name). If a named window is given but does not exist, UniqueName returns *baseName startSuffix*. *windowNameStr* is ignored for other *objectTypes*.

Examples

```
String uniqueWaveName = UniqueName(baseWaveName, 1, 0)
String uniqueControlName = UniqueName("ctrl", 15, 0, "Panel0")
```

See Also

CheckName and **CleanupName**.

Unwrap

Unwrap *modulus*, *waveName* [, *waveName*]...

The Unwrap operation scans through each named wave trying to undo the effect of a modulus operation.

Parameters

modulus is the value applied to the named waves through the **mod** function as if the command:

```
waveName = mod(waveName, modulus)
```

had been executed. It is this calculation which Unwrap attempts to undo.

Details

The unwrap operation works with 1D waves only. See **ImageUnwrapPhase** for phase unwrapping in two dimensions.

Examples

If you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave that contains the phase of the result of the FFT with the command:

```
wave2 = imag(r2polar(wave1))
```

However, the rectangular to polar conversion leaves the phase information modulo 2π . You can restore the phase information with the command:

```
Unwrap 2*pi, wave2
```

Because the first point of a wave that has been FFTed has no phase information, in this example you would *precede* the Unwrap command with the command:

```
wave2[0] = wave2[1]
```

See Also

The **ImageUnwrapPhase** operation and **mod** function.

UpperStr

UpperStr (*str*)

The UpperStr function returns a string expression in which all lower-case characters in *str* are converted to upper-case.

See Also

The **LowerStr** function.

ValDisplay

ValDisplay [/Z] *ctrlName* [*key* [= *value*]] [, *key* [= *value*]]...

The ValDisplay operation creates or modifies the named control that displays a numeric value in the target window. The appearance of the control varies; see the **Examples** section.

For information about the state or status of the control, use the **ControlInfo** operation.

Parameters

ctrlName is the name of the ValDisplay control to be created or changed.

key is one of the following parameters:

appearance={*kind* [, *platform*]}

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

kind can be one of **default**, **native**, or **os9**.

platform can be one of **Mac**, **Win**, or **All**.

See **Button** and **DefaultGuiControls** for more appearance details.

barmisc={*lts*, *valwidth*} Sets the “limits text size” and the size of the type showing the bar limits. If *lts* is zero, the bar limits are not displayed. Otherwise, *lts* must be between 5 and 100.

valwidth is the “value readout width”. It claims the amount of horizontal space for the numeric part of the display.

If *valwidth* equals or exceeds the control width available to it, the numeric readout uses all the room, and prevents display of any bar.

	<p>If <i>valwidth</i> is zero, there is no numeric readout, and only the bar is displayed. <i>valwidth</i> can range from zero to 4000, and it defaults to 1000 (which usually leaves no room for the display bar).</p>
<code>bodyWidth=width</code>	<p>Specifies an explicit size for the body (nontitle) portion of a ValDisplay control. By default (<code>bodyWidth=0</code>), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size, or text of the title changes, then the body portion may grow or shrink. If you supply a <code>bodyWidth>0</code>, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.</p>
<code>disable=d</code>	<p>Sets user editability of the control.</p> <p><i>d</i>=0: Normal.</p> <p><i>d</i>=1: Hide.</p> <p><i>d</i>=2: Disable user input. Does not change control appearance because it is read-only.</p>
<code>font="fontName"</code>	<p>Sets the font used to display the value of the variable, e.g., <code>font="Helvetica"</code>.</p>
<code>format=formatStr</code>	<p>Sets the numeric format of the displayed value. The default format is "%g". For a description of <i>formatStr</i>, see the printf operation.</p>
<code>frame=f</code>	<p>Sets frame style.</p> <p><i>f</i>=0: Value is unframed.</p> <p><i>f</i>=1: Default; value is framed (same as <i>f</i>=3).</p> <p><i>f</i>=2: Simple box.</p> <p><i>f</i>=3: 3D sunken frame.</p> <p><i>f</i>=4: 3D raised frame.</p> <p><i>f</i>=5: Text well.</p>
<code>fsize=s</code>	<p>Sets the size of the type used to display the value in the numeric readout. The default is 12 points.</p>
<code>fstyle=fs</code>	<p><i>fs</i> is a binary coded number with each bit controlling one aspect of the font style as follows:</p> <p>bit 0: Bold.</p> <p>bit 1: Italic.</p> <p>bit 2: Underline.</p> <p>bit 3: Outline (<i>Macintosh only</i>).</p> <p>bit 4: Shadow (<i>Macintosh only</i>).</p> <p>See Setting Bit Parameters on page IV-11 for details about bit settings.</p>
<code>help={helpStr}</code>	<p>Sets the help for the control. The help text is limited to a total of 255 characters. On Macintosh, help appears when you turn Igor Tips on. On Windows, help for the first 127 characters or up to the first line break appears in the status line. If you press F1 while the cursor is over the control, you will see the entire help text. You can insert a line break by putting "\r" in a quoted string.</p>
<code>highColor=(r,g,b)</code>	<p>Specifies the bar color when the value is greater than <i>base</i> in the limits keyword. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535.</p>
<code>labelBack=(r,g,b) or 0</code>	<p>Specifies the background fill color for labels. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535. The default is 0, which uses the window's background color.</p>
<code>limits={low,high,base}</code>	<p>Controls how the value is translated into a graphical representation when the display includes a bar (described fully in Details). Defaults are {0,0,0}, which aren't too useful.</p>
<code>lowColor=(r,g,b)</code>	<p>Specifies the bar color when the value is less than <i>base</i> in the limits keyword. <i>r</i>, <i>g</i>, and <i>b</i> are integers from 0 to 65535.</p>
<code>mode=m</code>	<p>Specifies the type of LED display to use, if any.</p> <p><i>m</i>=0: Bar mode (default).</p> <p><i>m</i>=1: Oval LED.</p>

	<i>m</i> =2: Rectangular LED.
	<i>m</i> =3: Bar mode with no fractional part.
<i>pos</i> = <i>{left,top}</i>	Sets position of display in pixels, from 0 to 2000.
<i>rename</i> = <i>newName</i>	Gives the ValDisplay control a new name.
<i>size</i> = <i>{width,height}</i>	Sets width and height of display in pixels. <i>width</i> can range from 10 to 200 pixels, <i>height</i> from 5 to 200 pixels. Default width is 50, default height is determined by the numeric readout font size.
<i>title</i> = <i>titleStr</i>	Sets title of display to the specified string expression. The title appears to the left of the display. If this title is too long, it won't leave enough room to display the bar or even the numeric readout!
<i>value</i> = <i>valExpr</i>	Displays the numeric expression <i>valExpr</i> . It is <i>not</i> a string.
<i>win</i> = <i>winName</i>	Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
<i>zeroColor</i> = <i>(r,g,b)</i>	Governs the LED color (in LED mode only). <i>r</i> , <i>g</i> , and <i>b</i> are integers from 0 to 65535. Used in conjunction with the <i>limits</i> keyword such that <i>zeroColor</i> determines one endpoint color when <i>base</i> is between <i>low</i> and <i>high</i> , or LED color when the value is less than <i>low</i> .

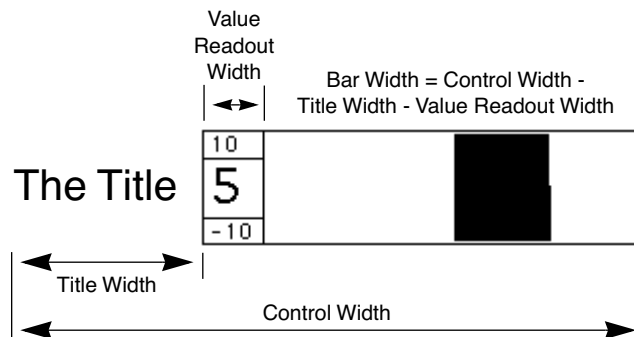

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The appearance of the ValDisplay control depends primarily on the *width* and *valwidth* parameters and the width of the title. Space for the individual elements is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value display gets either *valwidth* pixels of room, or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:

If you use the *bodyWidth* keyword, the value readout width and bar width occupy the body width. The total control width is then *bodyWidth*+title width, and the width from the *size* keyword is ignored.

The *limits* values *low*, *high*, and *base* and the value of *valExpr* control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the *base* value to an ending position determined by the value of *valExpr*, *low* and *high*. *low* corresponds to the left side of the bar, and *high* corresponds to the right. The position that corresponds to the *base* value is linearly interpolated between *low* and *high*.

For example, with *low*= -10, *high*=10, and *base*= 0, a *valExpr* value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):

The *valExpr* must be executable at any time. The expression is stored and executed when the ValDisplay needs to be updated. However, execution will occur outside the routine that creates the ValDisplay, so you must not use local variables in the expression.

valExpr may be enclosed in quotes and preceded with a # character (see **When Dependencies are Updated** on page IV-174) to defer evaluation of the validity of the numeric expression, which may be needed if the expression references as-yet-nonexistent global variables or user-defined functions:

```
ValDisplay valdisp0 value=notAVar*2           // "unknown name or symbol" error
ValDisplay valdisp0 value="#notAVar*2"        // still not valid, no error
Variable notAVar=3                             // now valid; ValDisplay works
```

In a ValDisplay, the # " " syntax permits use of a string expression. Normally, the # prefix signifies that the following text must be a literal quoted string. String expressions are evaluated at runtime to obtain the final expression for the ValDisplay. In other words, there is a level of indirection.

Examples

Here is a sampling of the various types of ValDisplay controls available:

You can use a ValDisplay to replace the bar mode with a solid color fill designed to look like an LED. Use the mode keyword with mode=1 to create an oval LED or mode=2 to create a rectangular LED. You can specify different frames with the rectangular LED but only a simple frame is available for the oval mode. Use mode=0 to revert to bar mode.

The color and brightness of the LED depends on the value that the ValDisplay is monitoring combined with the limits={*low*, *high*, *base*} setting, the two color settings used in bar mode along with a third color (zeroColor) that is used only in LED mode. When the value is between *low* and *high*, the color is a linear combination of endpoint colors. If *base* is between *low* and *high*, the endpoint colors are the low color and the zero color, or the zero color and the high color. For values outside the limits, the appropriate limiting color is chosen.

If *base* is less than the *low*, the endpoint colors are the low color and the high color. In this case, if the value is less than *low* the LED takes on the zero color.

You should use the bodyWidth setting in conjunction with LED mode to keep the LED from dramatically changing size or disappearing when the title is changed or if your experiment is moved to a different platform (Macintosh vs PC).

Try the ValDisplay Demo example experiment to see these different modes in action. The experiment file is in your Igor Pro folder, in the "Examples:Feature Demos" subfolder.

Variable

Variable [*flags*] *varName* [=numExpr][, *varName* [=numExpr]]...

The Variable declaration creates real or complex variables and gives them the specified name.

Flags

- /C Declares a complex variable.
- /D Obsolete, included only for backward compatibility (see **Details**).
- /G Creates a variable with global scope and overwrites any existing variable.

Details

The variable is initialized when it is created if you supply the initial value. You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.

As of Igor Pro 2.02 for Power Macintosh, Igor Pro 3.0 for all Macintoshes, and for all Windows versions, all numeric variables are double precision. Previously variables could be single or double precision and the /D flag meant double precision. The /D flag is allowed for backward compatibility but is no longer needed and should not be used in new code.

If used in a macro or function the new variable is local to that macro or function unless the /G (global) flag is used. If used on the command line, the new variable is global.

varName can include a data folder path.

Examples

To initialize a complex variable, use the **cmplx** function. For example:

```
Variable/C cv1 = cmplx(1,2)
```

sets the real part of cv1 to 1 and the imaginary part to 2.

VariableList

VariableList(*matchStr*, *separatorStr*, *variableTypeCode*)

The VariableList function returns a string containing a list of global variables selected based on the *matchStr* and *variableTypeCode* parameters. The variables listed are all in the current data folder.

Details

For a variable name to appear in the output string, it must match *matchStr* and also must fit the requirements of *variableTypeCode*. The first character of *separatorStr* is appended to each variable name as the output string is generated.

The name of each variable is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all variable names.
- "xyz" Matches variable name xyz only.
- "*xyz" Matches variable names which end with xyz.
- "xyz*" Matches variable names which begin with xyz.
- "*xyz*" Matches variable names which contain xyz.
- "abc*xyz" Matches variable names which begin with abc and end with xyz.

matchStr may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

- "!*xyz" Matches variable names which *do not* end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

variableTypeCode is used to further qualify the variable. The variable name goes into the output string only if it passes the match test and its type is compatible with *variableTypeCode*. *variableTypeCode* is any one of:

- 2: 32-bit (single precision) floating point numbers.
- 4: 64-bit (double precision) floating point numbers.

or a bitwise combination of the above for more than one type of variable. However, as of Igor Pro 3.0, only system numeric variables (K0, K1, ... K19, and *veclen*) are single precision, so you can usually use just 4 (double precision).

VariableList by default returns only real variables; to get a list of only complex variables, add one to *varTypeCode*:

- 1: For complex numbers only.

Examples

VariableList("*", ";", 4+2) Returns a list of all real single- and double-precision floating point variables.

VariableList("!V_*", ";", 4+1) Returns a list of all complex double-precision floating point variables except those whose names begin with "V_".

VariableList("*", ";", 6) + VariableList("*", ";", 7)
Returns a list of all variables in the current data folder.

See Also

See the **StringList** and **WaveList** functions.

See **Setting Bit Parameters** on page IV-11 for details about bit settings.

VCSR

vcsr(cursorName [, graphNameStr])

The vcsr function returns the Y (vertical) value of the point which the specified cursor (A through J) is attached to in the top (or named) graph.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The result is computed from the coordinate system of the graph's Y axis. The Y axis used is the one used to display the wave on which the cursor is placed.

See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **qcsr**, **xcscr**, and **zcscr** functions.

version

#pragma version = versNum

In the File Information dialog, **#pragma version=versNum** provides file version information that is displayed next to the file name in the dialog. This line must not be indented and must appear in the first five lines of the file. See **Procedure File Version Information** on page IV-120.

See Also

The **The version Pragma** on page IV-39, **Procedure File Version Information** on page IV-120, the **IgorInfo** function, and **#pragma**.

WAVE

WAVE [/C][/T][/Z] localName [=pathToWave][, localName1 [=pathToWave1]]...

WAVE is a reference that identifies the nature of a user-defined function parameter or creates a local reference to a wave accessed in the body of a user-defined function.

The optional parameter *pathToWave* is used only in the body of a function, not in a parameter declaration.

The WAVE reference is required when you use a wave in an assignment statement in a function. At compile time, the WAVE statement specifies that the local name references a wave. At runtime, it makes the connection between the local name and the actual wave. For this connection to be made, the wave must exist when the WAVE statement is executed.

When *localName* is the same as the global wave name and you want to reference a wave in the current data folder, you can omit the *pathToWave*. Prior to Igor Pro 4.0, *pathToWave* was always required.

pathToWave can be a full literal path (e.g., root:FolderA:wave0), a partial literal path (e.g., :FolderA:wave0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-48).

If the wave may not exist at runtime, use the /Z flag and call **WaveExists** before accessing the wave. The /Z flag prevents Igor from flagging a missing wave as an error and dropping into the debugger. For example:

```
WAVE/Z wv=<pathToPossiblyMissingWave>
if( WaveExists(wv) )
    <do something with wv>
endif
```

Note that to create a wave, you use the **Make** operation.

Flags

/C	Complex wave.
/T	Text wave.
/Z	Ignores wave reference checking failures.

See Also

WaveExists function and **Runtime Lookup of Globals** on page IV-50.

WAVE Reference Type Flags on page IV-55 for additional wave type flags and information.

Accessing Waves in Functions on page IV-57.

Accessing Global Variables and Waves on page IV-49.

Converting a String into a Reference Using \$ on page IV-48.

WAVEClear

WAVEClear *localName* [, *localName1* ...]

The WAVEClear operation clears out a WAVE reference variable. WAVEClear is equivalent to `WAVE/Z localName= $"`.

Details

Use WAVEClear to avoid unexpected results from certain operations such as **Duplicate** or **Concatenate**, which will reuse the contents of a WAVE reference variable and may not generate the wave in the desired data folder or with the desired name.

WAVEClear ensures that memory is deallocated after waves are killed as in this example:

```
Function foo()
    Make wave1
    FunctionThatKillsWave1()
    WAVEClear wave1
    AnotherFunction()
End
```

Although memory used for wave1 will be deallocated when `foo` returns, that memory will not be automatically released while the function executes because the WAVE variable still contains a reference to the wave. In this example, WAVEClear deallocates that memory before `AnotherFunction` executes.

You can also use WAVEClear before passing a data folder to preemptive threads using **ThreadGroupPutDF**.

See Also

Accessing Waves in Functions on page IV-57, **Wave Reference Counting** on page IV-151, and **ThreadSafe Functions and Multitasking** on page IV-214.

WaveCRC

WaveCRC(*inCRC*, *waveName* [, *checkHeader*])

The WaveCRC function returns 32 bit cyclic redundancy check value of the bytes in the named wave starting with *inCRC*, which should be zero for the first (or only) set of bytes.

waveName may be a numeric or text wave.

The optional *checkHeader* parameter determines how much of the wave is checked:

<i>checkHeader</i>	What It Does
0	Check only the wave data (default).
1	Check only the internal binary header.
2	Check both.

Details

Polynomial used is:

$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$

See `crc32.c` in the public domain source code for zlib for more information.

See Also

The **stringCRC** function.

WaveDims

WaveDims(*wave*)

The WaveDims function returns the number of dimensions used by *wave*.

Returns zero if wave reference is null. See **WaveExists** for a discussion of null wave references.

Also returns zero if wave has zero rows. A matrix will return 2.

WaveExists

WaveExists(*wave*)

The WaveExists function returns one if wave reference is valid or zero if the wave reference is null. For example if, in a user function, you have:

Wave w= \$"no such wave"

then WaveExists(w) will return zero.

WaveExists should be used in functions only. In macros, use the exists function instead.

See Also

exists, **NVAR_Exists**, **SVAR_Exists**, and **Runtime Lookup of Globals** on page IV-50.

WaveInfo

WaveInfo(*waveName*, 0)

The WaveInfo function returns a string containing a semicolon-separated list of information about the named wave.

Details

The string contains six kinds of information. Each group is prefaced by a keyword and colon, and terminated with a semicolon. The keywords are:

Keyword	Information Following Keyword
DUNITS	The data units (y scaling units, zero to three characters).
FULLSCALE	Three numbers indicating whether the wave has any data full scale information, and the min and max data full scale values. The format of the FULLSCALE description is: FULLSCALE: <i>validFS,minFS,maxFS</i> ;

Keyword	Information Following Keyword
	<i>validFS</i> is 1 if <i>minFS</i> and <i>maxFS</i> have been set via a SetScale d command; otherwise it is 0.
LOCK	Reads back the value set by SetWaveLock .
MODIFIED	1 if the wave has been modified since the experiment was last saved, else 0.
MODTIME	The date and time that the wave was last modified in seconds since January 1, 1904.
NUMTYPE	<p>A number denoting the numerical type of the wave:</p> <ul style="list-style-type: none"> 1: Complex, added to one of the following: 2: 32-bit (single precision) floating point 4: 64-bit (double precision) floating point 8: 8-bit signed integer 16: 16-bit signed integer 32: 32-bit signed integer 64: Unsigned, added to 8, 16, or 32 if wave is unsigned <p>For example, the number denoting a complex double precision wave is 5 (i.e., 1+4). See Setting Bit Parameters on page IV-11 for details about bit settings.</p>
PATH	The name of the symbolic path in which the wave file is stored (e.g., PATH:home;) or nothing if there is no path for the wave (PATH:;).
XUNITS	The X units (X scaling units, zero to three characters).

Always pass 0 as the second input parameter. In future versions of Igor, this parameter may request other kinds of information to be returned.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using **WaveRefIndexed** in a loop to act on all waves accessed by **WaveRefIndexed**, and the loop has incremented beyond the highest valid index.

Examples

```
Make/O wavel;SetScale x,0,1,"dyn",wavel;SetScale y,3,20,"v",wavel
String info = WaveInfo(wavel,0)
Print NumberByKey("NUMTYPE", info)           // Prints 2
Print StringByKey("DUNITS", info)             // Prints "v"
```

See Also

The functions and operations listed under “About Waves” categories in the Command Help tab of the Igor Help Browser; among them are **CreationDate**, **modDate**, **WaveType**, **note**, and **numpnts**.

NumberByKey and **StringByKey** functions for parsing the returned keyword list.

WaveInfo lacks information about multidimensional waves. Individual functions are provided to return dimension-related information: **DimDelta**, **DimOffset**, **DimSize**, **WaveUnits**, and **GetDimLabel**.

WaveList

WaveList(*matchStr*, *separatorStr*, *optionsStr*)

The **WaveList** function returns a string containing a list of waves selected from the current data folder based on *matchStr* and *optionsStr* parameters. See **Details** for information on listing waves in graphs, and for references to newer, data folder-aware functions.

Details

For a wave name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr* and it must be in the current data folder. The first character of *separatorStr* is appended to each wave name as the output string is generated.

The name of each wave is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything.

For example:

" * " Matches all wave names in current data folder.

WaveList

- "xyz" Matches wave name xyz only, if xyz is in the current data folder.
"*xyz" Matches wave names which end with xyz and are in the current data folder.
"xyz*" Matches wave names which begin with xyz and are in the current data folder.
"*xyz*" Matches wave names which contain xyz and are in the current data folder.
"abc*xyz" Matches wave names which begin with abc and end with xyz and are in the current data folder.

matchStr may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

- "!*xyz" Matches wave names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

optionsStr is used to further qualify the wave.

Use "" to accept all waves in the current data folder that are permitted by *matchStr*.

Set *optionsStr* to one or more of the following comma-separated keyword-value pairs:

<i>optionsStr</i>	Selection Criteria
"BYTE:0" or "BYTE:1"	Waves that are not 8-bit integer (if 0) or only waves that are 8-bit integer (if 1).
"CMPLX:0" or "CMPLX:1"	Waves that are not complex (if 0) or only waves that are complex (if 1).
"DIMS:numberOfDims"	All waves in current data folder that have <i>numberOfDims</i> dimensions. This is the number of dimensions reported by WaveDims . Use "DIMS:0" for all waves having no points (<code>numpts(w)==0</code>). Use "DIMS:1" for graph traces (or one of the X, Y, and Z waves of a contour plot). Use "DIMS:2" for false color and indexed color images (see Indexed Color Details on page II-333). Use "DIMS:3" for direct color images (see Direct Color Details on page II-336).
"DP:0" or "DP:1"	Waves that are not double precision floating point (if 0) or only waves that are double precision floating point (if 1).
"INTEGER:0" or "INTEGER:1"	Waves that are not 32-bit integer (if 0) or only waves that are 32-bit integer (if 1).
"MAXCHUNKS:max"	Waves having no more than <i>max</i> chunks.
"MAXCOLS:max"	Waves having no more than <i>max</i> columns.
"MAXLAYERS:max"	Waves having no more than <i>max</i> layers.
"MAXROWS:max"	Waves having no more than <i>max</i> rows.
"MINCHUNKS:min"	Waves having at least <i>min</i> chunks.
"MINCOLS:min"	Waves having at least <i>min</i> columns.
"MINLAYERS:min"	Waves having at least <i>min</i> layers.
"MINROWS:min"	Waves having at least <i>min</i> rows.
"SP:0" or "SP:1"	Waves that are not single precision floating point (if 0) or only waves that are single precision floating point (if 1).
"TEXT:0" or "TEXT:1"	Waves that are not text (if 0) or only waves that are text (if 1).
"UNSIGNED:0" or "UNSIGNED:1"	Waves that are not unsigned integer (if 0) or only waves that are unsigned integer (if 1).
"WIN:"	All waves in the current data folder that are displayed in the top graph or table.

<i>optionsStr</i>	Selection Criteria
"WIN:windowName"	All waves in the current data folder that are displayed in the named table or graph window or subwindow.
"WORD:0" or "WORD:1"	Waves that are not 16-bit integer (if 0) or only waves that are 16-bit integer (if 1).

You can specify more than one option by separating the options with a comma. See the **Examples**.

Note: Even when *optionsStr* is used to list waves used in a graph or table, the waves must be in the current data folder.

Note: In addition to waves displayed as normal graph traces, WaveList will list matrix waves used with **AppendImage** or NewImage and the X, Y, and Z waves used with **AppendXYZContour**.

Note: Individual contour traces are not listed because they have no corresponding waves. See **All About Contour Traces** on page II-306.

There are several functions that are more useful for listing waves in graphs and tables.

WaveList with WIN:windowName gives only the names of the waves in the graph or table and does not include the data folder for each wave. If you need to know what data folder the waves are in, use **WaveRefIndexed** to get the wave itself and then if needed use **GetWavesDataFolder** to get the path.

When identifying a subwindow with WIN:windowName, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

To list the actual waves used in a graph, or to distinguish two or more instances of the same named wave in a graph, use **TraceNameList**. This function can be used in conjunction with **TraceNameToWaveRef**, and **XWaveRefFromTrace**.

Use **ContourNameList** to list contour plots in a given window and **ContourNameToWaveRef** to access the waves used to generate the contour plot.

To list the contour traces (that is, the contour lines themselves) use **TraceNameList** with the appropriate option.

Use **ImageNameList** to list images in a given window and **ImageNameToWaveRef** to access the waves used to generate the images.

Examples

WaveList("*", ";", "")	Returns a list of all waves in the current data folder.
WaveList("*", ";", "WIN:")	Returns a list of all waves in the current data folder and displayed in the top table or graph.
WaveList("*_bkg", ";", "WIN:Graph0")	Returns a list of waves in the current data folder whose names end in "_bkg" and which are displayed in Graph0 as 1D traces.
WaveList("!*X", ";", "WIN:Graph0,DIMS:1")	Returns a list of waves in the current data folder whose names do not end in "X" and which are displayed in Graph0 as 1D traces or as one of the X, Y, and Z waves of an AppendXYZContour plot.

Contrary to what you might expect, you can *not* use the output of WaveList directly with operations that have a list of waves as their parameters. See **Processing Lists of Waves** on page IV-144 for ways of dealing with this.

Chapter II-6, **Multidimensional Waves**.

Execute, **ContourNameList**, **ImageNameList**, **TraceNameList**, and **WaveRefIndexed**.

waveMax

waveMax(waveName [, x1, x2])

The waveMax function returns the maximum value in the wave for points between x=x1 to x=x2, inclusive.

Details

If x1 and x2 are not specified, they default to -inf and +inf, respectively.

The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.

WaveMeanStdv

If the points nearest to $x1$ or $x2$ are not within the point range of 0 to `numpts(waveName)-1`, `waveMax` limits them to the nearest of point 0 or point `numpts(waveName)-1`.

For a floating-point wave, `waveMax` runs about three times faster than getting the same information using `waveStats`. For an integer wave, `waveMax` runs about ten times faster than `waveStats`. The advantage may not hold for short waves.

See Also

The **waveMin** function and **WaveStats** operation.

WaveMeanStdv

WaveMeanStdv *srcWave binSizeWave*

The `WaveMeanStdv` operation calculates the standard deviation of the means for the specified bin distribution saving the result in the wave `W_MeanStdv`.

For each entry in *binSizeWave*, *srcWave* is divided into the specified number of bins. Values in each bin are averaged and then the mean and standard deviation of the averages (among all bins) are calculated. The value of the standard deviation of the bin averages divided by the mean is then stored in `W_MeanStdv` corresponding to the bin size entry in *binSizeWave*.

All entries in *binSizeWave* must be positive integers.

Details

When the number of points in *srcWave* does not divide evenly into the bin size entry from *binSizeWave*, the last bin will have a smaller number of data points. In order not to skew the results the values corresponding to the last bin will be dropped. If your data set is small compared to the bin size you might want to pad *srcWave* with additional values (e.g., duplicate values from the beginning of the wave).

This operation does not support NaNs. If you get a NaN as an entry in the output wave then there is either a NaN in *srcWave* or something is wrong with the calculation for that entry.

waveMin

waveMin(*waveName* [, *x1*, *x2*])

The `waveMin` function returns the minimum value in the wave for points between $x=x1$ to $x=x2$, inclusive.

Details

If $x1$ and $x2$ are not specified, they default to `-inf` and `+inf`, respectively.

The X scaling of the wave is used only to locate the points nearest to $x=x1$ and $x=x2$. To use point indexing, replace $x1$ with `pnt2x(waveName,pointNumber1)`, and a similar expression for $x2$.

If the points nearest to $x1$ or $x2$ are not within the point range of 0 to `numpts(waveName)-1`, `waveMin` limits them to the nearest of point 0 or point `numpts(waveName)-1`.

For a floating-point wave, `waveMin` runs about three times faster than getting the same information using `waveStats`. For an integer wave, `waveMin` runs about ten times faster than `waveStats`. The advantage may not hold for short waves.

See Also

The **waveMax** function and **WaveStats** operation.

WaveName

WaveName(*winNameStr*, *index*, *type*)

The `WaveName` function returns a string containing the name of the *index*th wave of the specified *type* in the named window or subwindow.

Parameters

winNameStr can be `" "` to refer to the top graph or table.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

WaveName works on waves displayed in a graph, in a table or on the list of waves in the current data folder. If the window is a table, WaveName returns the column name (e.g., "wave0.d"), rather than the name of the wave itself (e.g., "wave0").

For most uses, we recommend that you use **WaveRefIndexed** instead of WaveName. WaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a data folder that is not the current data folder, you will not be able to refer to the named wave.

winNameStr is a string expression containing the name of a graph or table or the null string (""). If the string is null and *type* is 4 then WaveName works on the list of all waves in the current data folder. If the string is null and the type parameter is not 4 then WaveName works on the top graph or table.

index starts from zero.

type is a number from 1 to 4. When *type* is 4 and *winNameStr* is "", WaveName works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, *type* is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveName returns the null string ("") if there is no wave matching the parameters.

Examples

```
WaveName("",0,4)      // Returns name first wave current data folder.
WaveName("",0,1)      // Returns name of first Y wave in the top graph.
WaveName("Graph0",1,2) // Returns name of second X wave in Graph0.
WaveName("Table0",1,3) // Returns name of second column in Table0.
```

WaveRefIndexed**WaveRefIndexed(*winNameStr*, *index*, *type*)**

The WaveRefIndexed function returns a wave reference to the *index*th wave of the specified *type* in the named window or subwindow.

Parameters

winNameStr can be "" to refer to the top graph or table window or the current data folder.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

WaveRefIndexed is analogous to WaveName but works better with data folders. We recommend that you use it instead of WaveName.

winNameStr is a string expression containing the name of a graph or table or the null string (""). If the string is null and *type* is 4 then WaveRefIndexed works on Igor's list of all waves in the current data folder. If the string is null and the type parameter is not 4 then WaveRefIndexed works on the top graph or table.

index starts from zero.

type is a number from 1 to 4. When *type* is 4 and *winNameStr* is "", WaveRefIndexed works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, *type* is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveRefIndexed returns a null reference (see **WaveExists**) if there is no wave matching the parameters.

Examples

```
WaveRefIndexed("",0,4)      // Returns first wave in current data folder.
WaveRefIndexed("",0,1)      // Returns first Y wave in the top graph.
WaveRefIndexed("Graph0",1,2) // Returns second X wave in Graph0.
WaveRefIndexed("Table0",1,3) // wave in second column in Table0.
```

See Also

The **NameOfWave** and **GetWavesDataFolder** functions.

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

WaveStats

WaveStats [*flags*] *waveName*

The WaveStats operation computes several statistics on the named wave.

Flags

/ALPH= <i>val</i>	Sets the significance level for the confidence interval of the mean (default <i>val</i> =0.05).
/C= <i>method</i>	<p>Calculates statistics for complex waves only. Does not affect real waves.</p> <p>You can use <i>method</i> in various combinations to process the real, imaginary, magnitude, and phase of the wave. The result is stored in the wave M_WaveStats (see Details for format).</p> <p><i>method</i> =0: Default; ignores the imaginary part of <i>waveName</i>. Use /W to also store statistics in M_WaveStats.</p> <p><i>method</i> =1: Calculates statistics for real part of <i>waveName</i> and stores it in M_WaveStats.</p> <p><i>method</i> =2: Calculates statistics for imaginary part of <i>waveName</i> and stores the result in M_WaveStats.</p> <p><i>method</i> =4: Calculates statistics for magnitude of <i>waveName</i>, i.e., $\sqrt{\text{real}^2 + \text{imag}^2}$, and stores the result in M_WaveStats.</p> <p><i>method</i> =8: Calculate statistics for phase of <i>waveName</i> using $\text{atan2}(\text{imag}, \text{real})$.</p> <p>If you use a single <i>method</i> the results are stored both in M_WaveStats and in the standard variables (e.g., V_avg, etc.). If you specify <i>method</i> as a combination of more than one binary field then the variables reflect the results for the lowest chosen field and all results are stored in the wave M_WaveStats.</p> <p>For example, if you use /C=12, the variables will be set for the statistics of the magnitude and M_WaveStats will contain columns corresponding to the magnitude and to the phase.</p> <p>In this mode V_numInfs will always be zero.</p> <p>Note: if you invoke this operation and M_WaveStats already exists in the current data folder, it will be either overwritten or initialized to NaN.</p>
/M= <i>moment</i>	<p>Calculates statistical moments.</p> <p><i>moment</i> =1: Calculates only lower moments: V_avg, V_npnts, V_numInfs, and V_numNaNs. Use it if you do not need the higher moments.</p> <p><i>moment</i> =2: Default; calculates both lower moments and higher order quantities: V_sdev, V_rms, V_adev, V_skew, and v_kurt.</p>
/Q	Prevents results from being printed in history.
/R=(<i>startX</i> , <i>endX</i>)	Specifies an X range of the wave to evaluate.
/R=[<i>startP</i> , <i>endP</i>]	<p>Specifies a point range of the wave to evaluate.</p> <p>If you specify the range as /R=[<i>startP</i>] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is evaluated.</p>
/W	Stores results in the wave M_WaveStats in addition to the various V_ variables when /C=0.
/Z	No error reporting.
/ZSCR	Computes z scores, $z_i = (Y_i - \bar{Y}) / \sigma$, saved in W_ZScore.

Details

WaveStats uses a two-pass algorithm to produce more accurate results than obtained by computing the binomial expansions of the third and fourth order moments.

WaveStats returns the statistics in the automatically created variables:

V_npnts	Number of points. Does not include points whose value is NaN or INF.
V_numNaNs	Number of NaNs.

V_numINFs	Number of INFs.
V_avg	Average of Y values.
V_sdev	Standard deviation of Y values, $\sigma = \sqrt{\frac{1}{V_npnts - 1} \sum (Y_i - V_avg)^2}$. ("Variance" is V_sdev ² .)
V_rms	RMS (Root Mean Square) of Y values = $\sqrt{\frac{1}{V_npnts} \sum Y_i^2}$.
V_adev	Average deviation = $\frac{1}{V_npnts} \sum_{i=0}^{V_npnts-1} x_i - \bar{x} $.
V_skew	Skewness = $\frac{1}{V_npnts} \sum_{i=0}^{V_npnts-1} \left[\frac{x_i - \bar{x}}{\sigma} \right]^3$.
V_kurt	Kurtosis = $\frac{1}{V_npnts} \sum_{i=0}^{V_npnts-1} \left[\frac{x_i - \bar{x}}{\sigma} \right]^4 - 3$.
V_minloc	X location of minimum Y value.
V_min	Minimum Y value.
V_maxloc	X location of maximum Y value.
V_max	Maximum Y value.
V_minRowLoc	Row containing minimum Z value (2D or higher waves).
V_minColLoc	Column containing minimum Z value (2D or higher waves).
V_maxColLoc	Column containing maximum Z value (2D or higher waves).
V_maxRowLoc	Row containing maximum Z value (2D or higher waves).
V_minLayerLoc	Layer containing minimum Z value (3D or higher waves).
V_maxLayerLoc	Layer containing maximum Z value (3D or higher waves).
V_minChunkLoc	Chunk containing minimum Z value (4D waves only).
V_maxChunkLoc	Chunk containing maximum Z value (4D waves only).
V_startRow	First wave point. Zero if you do not use /R.
V_endRow	Last wave point. Last point if you do not use /R.

WaveStats prints the statistics in the history area unless /Q is specified. The various multidimensional min and max location variables will only print to the history area for waves having the appropriate dimensionality.

The format of the M_WaveStats wave is:

Row	Statistic	Row	Statistic	Row	Statistic
0	numPoints	9	minLoc	18	maxColLoc
1	numNaNs	10	min	19	maxLayerLoc
2	numInfs	11	maxLoc	20	maxChunkLoc
3	avg	12	max	21	startRow
4	sdev	13	minRowLoc	22	endRow
5	rms	14	minColLoc	23	sum
6	adev	15	minLayerLoc	24	meanL1

Row	Statistic	Row	Statistic	Row	Statistic
7	skew	16	minChunkLoc	25	meanL2
8	kurt	17	maxRowLoc		

meanL1 and meanL2 are the confidence intervals for the mean

$$MeanL1 = V_avg - t_{\alpha,v} \frac{V_sdev}{\sqrt{V_npnts}} \text{ and } MeanL2 = V_avg + t_{\alpha,v} \frac{V_sdev}{\sqrt{V_npnts}}$$

where $t_{\alpha,v}$ is the critical value of the Student T distribution for α significance and degree of freedom $v=V_npnts-1$.

Use `Edit M_WaveStats.1d` to display the results in a table with dimension labels identifying each of the row statistics.

WaveStats is not entirely multidimensional aware. Even so, much of the information computed by WaveStats is useful. See **Analysis on Multidimensional Waves** on page II-94 for details.

See Also

Chapter III-12, **Statistics** for a function and operation overview.

The **ImageStats** operation for calculating wave statistics for specified regions of interest in 2D matrix waves.

WaveTransform

WaveTransform [*flags*] keyword *srcWave*

The WaveTransform operation transforms *srcWave* in various ways. If the /O flag is not specified then unless otherwise indicated the output is stored in the wave W_WaveTransform, which will be of the same data type as *srcWave* and saved in the current data folder.

Parameters

keyword is one of the following:

abs	Calculates the absolute value of the entries in <i>srcWave</i> . It stores results in W_Abs if <i>srcWave</i> is 1D or M_Abs otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
acos	Calculates the inverse cosine of the entries in <i>srcWave</i> . It stores results in W_Acos if <i>srcWave</i> is 1D or M_Acos otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
asin	Calculates the inverse sine of the entries in <i>srcWave</i> . It stores results in W_Asin if <i>srcWave</i> is 1D or M_Asin otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
atan	Calculates the inverse tangent of the entries in <i>srcWave</i> . It stores results in W_Atan if <i>srcWave</i> is 1D or M_Atan otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
cconjugate	Calculates the complex conjugate of <i>srcWave</i> . Stores results in W_CConjugate or M_CConjugate, depending on wave dimensionality, or overwrites <i>srcWave</i> if /O is used.
cos	Calculates the cosine of the entries in <i>srcWave</i> . It stores results in W_Cos if <i>srcWave</i> is 1D or M_Cos otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.
crystalToRect	Converts triplet (three column {x,y,z}) waves from nonorthogonal crystallographic coordinates to rectangular cartesian system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation sets the first component parallel to the vector a and the third component parallel to c*. The output is stored in the current data folder in the wave M_CrystalToRect which has the same data type. If the /O flag is specified, the output overwrites the original data.
flip	Flips the data in <i>srcWave</i> about its center. If /O flag is used, <i>srcWave</i> is overwritten. Otherwise a new wave is created in the current data folder. The wave is named W_flipped or M_flipped according to the dimensionality of <i>srcWave</i> .

index	Fills <i>srcWave</i> as in <i>jack=p</i> . If /P is specified then <i>jack=p+param1</i> . The /O flag does not apply here.
inverse	Computes $1/\text{srcWave}[i]$ for each point in <i>srcWave</i> and stores it in W_Inverse or M_Inverse depending on the dimensionality of <i>srcWave</i> .
inverseIndex	Fills <i>srcWave</i> as in <i>jack=numPnts-1-p</i> . If /P is specified the <i>jack=numPnts-1-p+param1</i> .
magnitude	Creates a real-valued wave that is the magnitude of <i>srcWave</i> . If you do not specify the /O flag, the output is stored in W_Magnitude or M_Magnitude depending on the dimensionality of <i>srcWave</i> ; the output precision will be the same as <i>srcWave</i> .
magsqr	Creates a real-valued wave that is the magnitude squared of <i>srcWave</i> . If <i>srcWave</i> is a double precision complex wave, the output is also double precision, otherwise the output is a single precision wave. Stores the result in wave W_MagSqr or M_MagSqr, depending on the dimensionality of <i>srcWave</i> , or overwrites <i>srcWave</i> if /O is used.
max	Calculates the maximum of a point in <i>srcWave</i> and a fixed number specified as a single parameter with the /P flag. It stores results in W_max if <i>srcWave</i> is 1D or M_max otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. See also the max keyword and examples.
min	Calculates the minimum of a point in <i>srcWave</i> and a fixed number specified as a single parameter with the /P flag. It stores results in W_min if <i>srcWave</i> is 1D or M_min otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. See also the max keyword and examples.
normalizeArea	Calculates the area under the curve and rescales the wave so that the area is 1. Note that waves with negative areas will be rescaled to positive values. Applies to 1D real-valued waves. It does not affect wave scaling. Stores the result in the wave W_normalizedArea or overwrites <i>srcWave</i> if /O is used.
phase	Creates a real-valued wave containing the phase of the complex input wave. If the /O flag is not used, the output is stored in W_Phase or M_Phase depending on the dimensionality of <i>imageMatrix</i> . You can also use /P={ <i>norm</i> } to divide the output wave by the value of <i>norm</i> .
rectToCrystal	Converts triplet (three column {x,y,z}) waves from cartesian coordinates to nonorthogonal crystallographic coordinate system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation assumes the first component parallel to the vector a and the third component parallel to c*. The output is stored in the current data folder in the wave M_RectToCrystal which has the same data type. If the /O flag is specified, the output overwrites the original data.
sgn	Sets the value to -1 if the entry is negative, 1 otherwise. Stores the results in W_Sgn or overwrites <i>srcWave</i> if /O is used. This operation will not work on UNSIGNED waves.
shift	Shifts the position of data in <i>srcWave</i> by the specified number of points. Unlike Rotate, WaveTransform discards data points that shift outside existing wave boundaries. After the shift, vacated wave points are set to the specified <i>fillValue</i> . The shift and the <i>fillValue</i> are specified with the /P flag using the syntax: /P={ <i>numPoints</i> , <i>fillValue</i> }. If you do not provide a fill value, it will be 0 for integer waves and NaN for SP and DP.
sqrt	Calculates the square root of the entries in <i>srcWave</i> . It stores results in W_sqrt if <i>srcWave</i> is 1D or M_sqrt otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single- or double-precision real wave.
tan	Calculates the tangent of the entries in <i>srcWave</i> . The results are stored in W_tan if <i>srcWave</i> is 1D or M_tan otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single- or double-precision real wave.
Flags	
/D	Specifies that angles are in degrees.
/O	Overwrites input wave.

WaveType

`/P={param1...}` Specifies parameters as appropriate for the keyword that you are using. The number of parameters and their order depends on the keyword.

Examples

Produce output values in the range [-1,1]:

```
Wavetransform /P={pi} phase complexWave
```

```
WaveTransform /P={1}/O min myWave // faster than myWave=myWave>1 ? 1 : myWave
```

See Also

The **Rotate** operation.

References

Shmueli, U. (Ed.), International Tables for Crystallography, Volume B: 3.3, Kluwer Academic Publishers, Dordrecht, The Netherlands, 1996.

WaveType

WaveType(waveName)

The WaveType function returns the type of data stored in the wave.

The returned value will be zero for a text wave. Numeric waves will return a combination of bit values:

Type	Bit Number	Decimal Value	Hexadecimal Value
complex	0	1	1
32-bit float	1	2	2
64-bit float	2	4	4
8-bit integer	3	8	8
16-bit integer	4	16	10
32-bit integer	5	32	20
unsigned	6	64	40

The unsigned bit is used only with the integer types while the complex bit can be used with any. Only one of the bits 1-5 are set at a time. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Examples

```
Variable waveIsComplex = WaveType(wave) & 0x01
Variable waveIs32BitFloat = WaveType(wave) & 0x02
Variable waveIs64BitFloat = WaveType(wave) & 0x04
Variable waveIs8BitInteger = WaveType(wave) & 0x08
Variable waveIs16BitInteger = WaveType(wave) & 0x10
Variable waveIs32BitInteger = WaveType(wave) & 0x20
Variable waveIsUnsigned = WaveType(wave) & 0x40
```

WaveUnits

WaveUnits(waveName, dimNumber)

The WaveUnits function returns a string containing the units for the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. Use -1 to get the data units. If the wave is just 1D, *dimNumber*=0 returns X units and 1 returns data units. This behavior is just like the WaveMetrics procedure WaveUnits found in the WaveMetrics Procedures folder in previous versions of Igor Pro.

wfprintf

wfprintf *refNum*, *formatStr* [*flags*] *waveName* [, *waveName*]...

The **wfprintf** operation is like **printf** except that it prints the contents of the named waves to a file whose file reference number is in *refNum*.

The **Save** operation also outputs wave data to a text file. Use **Save** unless you need the added flexibility provided by **wfprintf**.

Parameters

refNum is a file reference number from the **Open** operation used to create the file.

The value of each named wave is printed to the file according to the conversion specified in *formatStr*.

formatStr contains one numeric conversion specification per column. See **printf**. If *formatStr* is " ", **wfprintf** uses a default format which gives tab-delimited columns.

Flags

/R=(*startX*,*endX*) Specifies an X range in the wave(s) to print.

/R=[*startP*,*endP*] Specifies a point range in the wave(s) to print.

If you use the /R flag, you must not put a comma between format and /R.

Details

A complex wave in the wavelist is treated as two separate columns and requires two separate conversion specifications if you do not use the default " " specification.

The number of conversion characters must exactly match the number of columns (one column per real wave, two columns per complex wave) in the wave list. The wave list is limited to 100 waves. You can output up to 200 columns by using complex waves instead of real waves.

The only conversion characters allowed are: fFeEgdouxXc (the floating point and integer conversion characters). You cannot use an asterisk to specify field width or precision.

If any of these restrictions is intolerable, you can use **fprintf** in a loop.

The **wfprintf** operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-94 for details.

The **wfprintf** operation supports numeric (real only) and string fields from structures. All other field type will cause a compile error.

See Also

The **printf** operation for complete format and parameter descriptions and **Creating Formatted Text** on page IV-184. The **Open** operation about *refNum* and for another way of writing wave files.

The **Save** operation.

WhichListItem

WhichListItem(*itemStr*, *listStr* [, *listSepStr* [, *startIndex* [, *matchCase*]])

The **WhichListItem** function returns the index of the first item of *listStr* that matches *itemStr*. *listStr* should contain items separated by the *listSepStr* character, such as "abc;def;". If the item is not found in the list, -1 is returned.

Use **WhichListItem** to locate an item in a string containing a list of items separated by a single character, such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

listSepStr, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

Details

WhichListItem differs from **FindListItem** in that **WhichListItem** returns a list index, while **FindListItem** returns a character offset into a string.

listStr is searched for *itemStr* bound by *listSepStr* on the left and right.

listStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

WignerTransform

If *itemStr* is not found, if *listStr* is " ", or if *startIndex* is not within the range of 0 to *ItemsInList(listStr)*-1, then -1 is returned.

Only the first character of *listSepStr* is used.

Items can be empty. The lists "abc;def;;ghi" and ";abc;def;;ghi;" have four items (the third item is ""). Use *WhichListItem(" ", listStr)* to find the first empty item.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

Examples

```
Print WhichListItem("wave0", "wave0;wave1;")           // prints 0
Print WhichListItem("c", "a;b;")                       // prints -1
Print WhichListItem("", "a;b;")                       // prints 1
Print WhichListItem("c", "a,b,c,x,c", ",")           // prints 2
Print WhichListItem("c", "a,b,c,x,c", ",", 3)         // prints 4
Print WhichListItem("C", "x;c;C;")                   // prints 2
Print WhichListItem("C", "x;c;C;", ";", 0, 0)         // prints 1
```

WignerTransform

WignerTransform [/Z][/WIDE=*wSize*][/GAUS=*gaussianWidth*][/DEST=*destWave*] *srcWave*

The *WignerTransform* operation computes the Wigner transformation of a 1D signal in *srcWave*, which is the name of a real or complex wave. The result of the *WignerTransform* is stored in *destWave* or in the wave *M_Wigner* in the current data folder.

Flags

/DEST=*destWave* Creates by default a real wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-53 for details.

/GAUS=*gWidth* Computes the Gaussian Wigner Transform, which is a convolution of the Wigner Transform with a two-dimensional Gaussian (in the two parameters of the transform). The computation of the transform simplifies significantly when the product of the widths of the two Gaussians is unity (minimum uncertainty ellipse).
gWidth uses the same units as the *srcWave* scaling.

/WIDE=*wSize* Computes Wigner Transform and sets the transform width to *wSize*. This is the default transformation with *wSize* set to the size of *srcWave*.

/Z No error reporting.

Details

The Wigner transform maps a time signal $U(t)$ into a 2D time-frequency representation:

$$W(t, \nu) = \int_{-\infty}^{\infty} U\left(t + \frac{x'}{2}\right) U^*\left(t - \frac{x'}{2}\right) e^{-2\pi i x' \nu} dx'.$$

The computation of the Wigner transform evaluates the offset product

$$U\left(t + \frac{x'}{2}\right) U^*\left(t - \frac{x'}{2}\right)$$

over a finite window and then Fourier transforms the result. The offset product can be evaluated over a finite window width, which can vary from a few elements of the input wave to the full length of the wave. You can control the width of this window using the /WIDE flag. If you do not specify the output destination, *WignerTransform* saves the results in the wave *M_Wigner* in the current data folder.

The input wave can be of any numeric data type, and the output data type and precision will be the same as the input. Although the Wigner transform is real, the output will be complex when *srcWave* is complex. By inspecting the complex wave you can gain some insight into the numerical stability of the algorithm. The X-scaling of the output wave is identical to the scaling of *srcWave*. The Y-scaling of the input wave is taken from the Fourier Transform of the offset product, which in turn is determined by the X-scaling of

srcWave. Specifically, if $dx = \text{DimDelta}(\text{srcWave}, 0)$ and *srcWave* has N points then $dy = \text{DimDelta}(\text{M_Wigner}, 1) = 1 / (dx * N)$. WignerTransform does not set the units of the output wave. The Ambiguity Function is related to the Wigner Transform by a Fourier Transform, and is defined by

$$A(\tau, \nu) = \int_{-\infty}^{\infty} U\left(t + \frac{\tau}{2}\right) U^*\left(t - \frac{\tau}{2}\right) e^{-2\pi i \nu t} dt.$$

Convolving the Wigner Transform with a 2D Gaussian leads to what is sometimes called the Gaussian Wigner Transform or GWT. Formally the GWT is given by the equation:

$$GWT(t, \nu; \delta_t, \delta_\nu) = \frac{1}{\delta_t \delta_\nu} \iint dt' dv' W(t', \nu') e^{-2\pi \left(\frac{t-t'}{\delta_t}\right)^2} e^{-2\pi \left(\frac{\nu-\nu'}{\delta_\nu}\right)^2}.$$

Computationally this equation simplifies if the respective widths of the two Gaussians satisfy the minimum uncertainty condition $\delta_t^* \delta_\nu = 1$. The /Gaus flag calculates the Gaussian Wigner Transform using your specified width, δ_t , and it selects a δ_ν such that it satisfies the minimum uncertainty condition.

Window

Window *macroName*([*parameters*]) [:*macro type*]

The Window keyword introduces a macro that recreates a graph, table, layout, or control panel window. The macro appears in the appropriate submenu of the Windows menu. Window macros are automatically created when you close a graph, table, layout, control panel, or XOP target window (e.g., surface plot). You should use **Macro**, **Proc**, or **Function** instead of Window for your own window macros. Otherwise, it works the same as **Macro**.

See Also

The **Macro**, **Proc**, and **Function** keywords. **Data Folders and Window Macros** on page II-109 for details.

Macro Syntax on page IV-80 for further information.

WindowFunction

WindowFunction [/FFT[=*f*] /DEST=*destWave*] *windowKind*, *srcWave*

The WindowFunction operation multiplies a one-dimensional (real or complex) *srcWave* by the named window function.

By default the result overwrites *srcWave*.

Parameters

srcWave A one-dimensional wave of any numerical type. See **ImageWindow** for windowing two-dimensional data.

windowKind Specifies the windowing function, which are listed in bold (some windows, in italics, have multiple options for different constant values). The equations assume that /FFT=1:

Bartlett: a synonym for Bartlett.

$$\text{Bartlett: } w(n) = \begin{cases} \frac{n}{N-1} & n = 0, 1, \dots, \frac{N}{2} \\ W(N-n) & n = \frac{N}{2}, \dots, N-1 \end{cases}.$$

Blackman: $w(n) = a_0 - a_1 \cos\left(\frac{2\pi}{N}n\right) + a_2 \cos\left(\frac{2\pi}{N}2n\right) - a_3 \cos\left(\frac{2\pi}{N}3n\right) \quad .$

$$n = 0, 1, 2, \dots, N-1$$

<i>windowKind</i>	a_0	a_1	a_2	a_3
Blackman367	0.42323	0.49755	0.07922	
Blackman361	0.44959	0.49364	0.05677	
Blackman492	0.35875	0.48829	0.14128	0.01168
Blackman474	0.40217	0.49703	0.09392	0.00183

Cos: $w(n) = \cos\left(\frac{n}{N}\pi\right)^\alpha \quad n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2}$

Cos1: $\alpha = 1.$

Cos2: $\alpha = 2.$

Cos3: $\alpha = 3.$

Cos4: $\alpha = 4.$

Hamming: $w(n) = \begin{cases} 0.54 + 0.46 \cos\left(\frac{2\pi}{N}n\right) & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ 0.54 - 0.46 \cos\left(\frac{2\pi}{N}n\right) & n = 0, 1, 2, \dots, N-1 \end{cases} .$

Hanning: $w(n) = \begin{cases} \frac{1}{2} \left[1 + \cos\left(\frac{2n}{N}\pi\right) \right] & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ \frac{1}{2} \left[1 - \cos\left(\frac{2n}{N}\pi\right) \right] & n = 0, 1, 2, \dots, N-1 \end{cases} .$

Kaiser Bessel: $w(n) = \frac{I_0\left(\pi\alpha \sqrt{1 - \left(\frac{n}{N/2}\right)^2}\right)}{I_0(\pi\alpha)} \quad 0 \leq |n| \leq \frac{N}{2} .$

$$I_0(X) = \sum_{k=0}^{\infty} \left(\frac{(X/2)^{2k}}{k!} \right)^2$$

KaiserBessel20: $\alpha = 2.$

KaiserBessel25: $\alpha = 2.5.$

KaiserBessel30: $\alpha = 3.$

Parzen: $w(n) = 1 - \left| \frac{n}{N/2} \right|^2 \quad 0 \leq |n| \leq \frac{N}{2} .$

Poisson: $w(n) = \exp\left(-\alpha \frac{|n|}{N/2}\right) \quad 0 \leq |n| \leq \frac{N}{2} .$

Poisson2: $\alpha = 2.$

Poisson3: $\alpha = 3.$

Poisson4: $\alpha = 4.$

Riemann: $w(n) = \frac{\sin\left(\frac{n}{N}2\pi\right)}{\left(\frac{n}{N}2\pi\right)} \quad 0 \leq |n| \leq \frac{N}{2} .$

Flags

`/DEST=destWave` Creates or overwrites *destWave* with the result of the multiplication of *srcWave* and the window function.

When used in a function, the WindowFunction operation by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE**

References on page IV-53 for details.

`/FFT [=1]`

The window interval is $0 \dots N = \text{numpts}(\text{srcWave})$. This sets the first value of *srcWave* to zero, but not the last value. This is appropriate for windowing data in preparation for Fourier Transforms, and is the same algorithm used by **FFT**.

The window interval is $0 \dots N = \text{numpts}(\text{srcWave}) - 1$ if `/FFT` is missing or `/FFT=0`. This sets the first and last value of *srcWave* to 0. This is the (only) algorithm that the Hanning operation uses.

Details

A “window function” alters the input data by decreasing values near the start and end of the data smoothly towards zero, so that when the FFT of the data is computed the effects of nonintegral-periodic signals are diminished. This improves the ability of the FFT to distinguish among closely-spaced frequencies. Each window function has advantages and disadvantages, usually trading off rejection of “leakage” against the ability to discriminate adjacent frequencies. For more details, see the **References**.

WindowFunction stores the window function’s normalization value (the average squared window value) in *V_value*. This is the value you would get from WaveStats’s *V_rms*V_rms* for a wave of *srcWave*’s length whose values were all equal to 1:

```
Make/O data = 1
WindowFunction Bartlet, data           // Bartlet allowed as synonym for Bartlett
Print V_value                          // Prints 0.330709, mean of squared window values
```

```
WaveStats/Q data
Print V_rms*V_rms                      // Prints 0.330709
```

See Also

FFT and **ImageWindow** operations.

References

For more information about the use of window functions see:

Harris, F.J., On the use of windows for harmonic analysis with the discrete Fourier Transform, *Proc, IEEE*, 66, 51-83, 1978.

Wikipedia entry: <http://en.wikipedia.org/wiki/Window_function>.

WinList

WinList(matchStr, separatorStr, optionsStr)

The WinList function returns a string containing a list of windows selected based on the *matchStr* and *optionsStr* parameters.

Details

For a window name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr*. The first character of *separatorStr* is appended to each window name as the output string is generated.

The name of each window is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

```
"*"           Matches all window names
"xyz"         Matches window name xyz only
"*xyz"        Matches window names which end with xyz
```

"xyz*" Matches window names which begin with xyz
"*xyz*" Matches window names which contain xyz
"abc*xyz" Matches window names which begin with abc and end with xyz

matchStr may begin with the ! character to return windows that do not match the rest of *matchStr*. For example:

"!*xyz" Matches window names which *do not* end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

optionsStr is used to further qualify the window. The acceptable values for *optionsStr* are:

" "	Consider all windows.
"WIN: "	The target window.
"WIN: <i>windowTypes</i> "	Consider windows that match <i>windowTypes</i> .
"INCLUDE: <i>includeTypes</i> "	Consider procedure windows that match <i>includeTypes</i> .
"INDEPENDENTMODULE: 1"	If <code>SetIgorOption independentModuleDev=1</code> , then consider procedure windows that are part of any independent module.
	If <code>SetIgorOption independentModuleDev=0</code> or if <code>INDEPENDENTMODULE: 0</code> , then procedure windows that are part of any independent module are not listed.

windowTypes is a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with *windowTypes*. *windowTypes* is one of:

- 1: Graphs.
- 2: Tables.
- 4: Layouts.
- 16: Notebooks.
- 64: Panels.
- 128: Procedure windows.
- 4096: XOP target windows (e.g., surface plots).

or a bitwise combination of the above for more than one type of inclusion. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Procedure windows don't have names. WinList returns the procedure window title instead.

includeTypes is also a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with *includeTypes*. *includeTypes* is one of:

- 1: Procedure windows that are not #included.
- 2: Procedure windows included by `#include "someFileName"`.
- 4: Procedure windows included by `#include <someFileName>`.

or a bitwise combination of the above for more than one type of inclusion.

You can combine the WIN, INCLUDE and INDEPENDENTMODULE options by separating them with a comma.

When executing `SetIgorOption independentModuleDev=1` after opening the current experiment, the title of any procedure window in an independent module will be followed by [*nameOfIndependentModule*].

For example, if a procedure file contains:

```
#pragma IndependentModule=myIndependentModule
#include <Axis Utilities>
```

A call to WinList like this:

```
String procedureWindows = WinList("*, ", ";", "WIN:128,INCLUDE:8")
```

will store "Axis Utilities.ipf [myIndependentModule];" into the *procedureWindows* string, along with any other procedure windows that are part of that independent module. The procedure window that contains the

```
#pragma IndependentModule=myIndependentModule
```

statement is also listed with the independent module name.

To get a list of procedure windows that comprise a particular independent module, you can use a call such as:

```
SetIgorOption IndependentModuleDev=1
list= WinList("* [myIndependentModule]", ";", "WIN:128,INDEPENDENTMODULE:1")
```

Examples

Command	Returned List
<code>WinList("",";","")</code>	All existing windows.
<code>WinList("",";","WIN:3")</code>	All graph and table windows.
<code>WinList("Result_*",";","WIN:1")</code>	Graphs whose names start with "Result_".
<code>WinList("",";","INCLUDE:6")</code>	All #included procedure windows.
<code>WinList("",";","WIN:1,INCLUDE:6")</code>	All graphs and #included procedure windows.

See Also

The **IndependentModule Pragma** on page IV-40. The **ChildWindowList** and **WinType** functions.

WinName

WinName(index, windowTypes [, visibleWindowsOnly])

The WinName function returns a string containing the name of the *index*th window of the specified *type*, or the null string (" ") if no window fits the parameters.

If the optional *visibleWindowsOnly* is nonzero, only visible windows are considered (the default is both visible and hidden windows).

Procedure windows don't have names. WinName returns the procedure window title instead.

Details

index starts from zero, and returns the top-most window matching the parameters.

The window names are ordered in window-stacking order, as returned by WinList.

DoWindow/B moves the window to the back and changes the index needed to retrieve its name to the greatest index that returns any name.

Hiding or showing a window (with **SetWindow** *hide*=1 or **Notebook** *visible*=0 or by manual means) does not affect the index associated with the window.

windowTypes is one of:

- 1: Graphs.
- 2: Tables.
- 4: Layouts.
- 16: Notebooks.
- 64: Panels.
- 128: Procedure windows.
- 4096: XOP target windows (e.g., surface plots).

or a bitwise combination of the above for more than one type of window. See **Setting Bit Parameters** on page IV-11 for details about bit settings.

Examples

```
Print WinName(0,1)           // Prints the name of the top graph.
Print WinName(0,3)           // Prints the name of the top graph or table.
String win=WinName(0,1)      // The name of the top visible graph.
SetWindow $win hide=1        // Hide the graph (it may already be hidden).
Print WinName(0,1)           // Prints the name of the now-hidden graph.
Print WinName(0,1,1)         // Prints the name of the top visible graph.
```

See Also

The **WinList**, **DoWindow** (/F and /B flags), **SetWindow** (hide keyword), and **Notebook** (Miscellaneous) (visible keyword) operations.

WinRecreation

WinRecreation(winNameStr, options)

The WinRecreation function returns a string containing the window recreation macro (or style macro) for the named window.

Details

If *winNameStr* is "", the macro for the top graph, table, page layout, panel, notebook, or XOP target window is returned.

If *options* is 0, WinRecreation returns the window recreation macro.

If *options* is 1, WinRecreation returns the style macro or an empty string if the window does not support style macros.

Graphs Details

If *options* is 2, WinRecreation returns a recreation macro in which all occurrences of wave names are replaced with an ID number having the form ##<number>## (for instance, ##25##). These ID numbers can be found easily using the **strsearch** function. This is intended for applications that need to alter the recreation macro by replacing wave names with something else, usually other wave names. The ID numbers are the same as those returned by the **GetWindow** operation with the wavelist keyword.

Graphs and Panels Details

If *options* is 4, WinRecreation returns the window recreation macro without the default behavior of causing the graph to revert to "normal" mode (as if the GraphNormal operation had been called). This allows the use of WinRecreation when a graph or panel is in drawing tools mode without exiting that mode. For windows other than graphs or panels, this is equivalent to an *options* value of 0.

Notebooks Details

If *options* is -1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Selected paragraphs radio button selected and all the checkboxes selected (includes text commands).

If *options* is 0, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes *except* "Generate text commands" selected).

If *options* is 1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes selected (includes text commands).

Regardless of the value of *options* the text returned by WinRecreation for notebook always ends with 5 lines of file-related information formatted as comments:

```
// File Name: MyNotebook.txt
// Path: "Macintosh HD:Desktop Folder:"
// Symbolic Path: home
// Selection Start: paragraph 100, position 31
// Selection End: paragraph 100, position 31
```

Examples

```
WinRecreation("Graph0",0)           // Returns recreation macro for Graph0.
WinRecreation("",1)                  // Style macro for top window.
String win= WinName(0,16,1)          // top visible notebook
String str= WinRecreation(str,-1)    // Selected Text commands
Variable line= itemsInList(str,"\r")-5 // First file info line
Print StringFromList(line, str,"\r") // Print File Name:
Print StringFromList(line+1, str,"\r") // Print Path:
Print StringFromList(line+2, str,"\r") // Print Symbolic Path:
Print StringFromList(line+3, str,"\r") // Selection Start:
Print StringFromList(line+4, str,"\r") // Selection End:
```

See Also

Saving a Window as a Recreation Macro on page II-51.

WinType

WinType(*winNameStr*)

The WinType function returns a value indicating the type of the named window.

Details

winNameStr is a string or string expression containing the name of a window or subwindow, or "" to signify the target window. When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

WinType returns the following values:

- 0: No window by that name.
- 1: Graph.
- 2: Table.
- 3: Layout.
- 5: Notebook.
- 7: Panel.
- 13: XOP target window (e.g., surface plot).

Because command and procedure windows do not have *names* (they only have *titles*), WinType can not even be asked about those windows.

See Also

The **WinName**, **ChildWindowList**, and **WinList** functions.

wnoise

wnoise(*shape*, *scale*)

The wnoise function returns a pseudo-random value from the two-parameter Weibull distribution characterized by the *shape* and *scale*, the respective *g* and *a* parameters. The two-parameter Weibull probability distribution function is

$$f(x, \alpha, \gamma) = \frac{\gamma}{\alpha} \left(\frac{x}{\alpha} \right)^{\gamma-1} \exp \left[- \left(\frac{x}{\alpha} \right)^{\gamma} \right] \quad \begin{array}{l} x \geq 0 \\ \gamma > 0 \\ \alpha > 0 \end{array}$$

The mean of the Weibull distribution is

$$\alpha^{\frac{1}{\gamma}} \Gamma \left(1 + \frac{1}{\gamma} \right)$$

and the variance is

$$\alpha^{\frac{2}{\gamma}} \Gamma \left(1 + \frac{2}{\gamma} \right) - \alpha^{\frac{2}{\gamma}} \left[\Gamma \left(1 + \frac{1}{\gamma} \right) \right]^2$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

Chapter III-12, **Statistics** for a function and operation overview; **SetRandomSeed**.

x

x

The x function returns the scaled row index for the current point of the destination wave in a wave assignment statement. This is the same as the X value if the destination wave is a vector (1D wave).

Details

Outside of a wave assignment statement, *x* acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also

The **p** function and **Waveform Arithmetic and Assignments** on page II-80.

x2pnt

x2pnt(waveName, x1)

The x2pnt function returns the point number on the wave whose X value is closest to *x1*.

Details

There are no equivalent functions for multidimensional waves. To calculate this information for other dimensions, use this expression:

$(ScaledDimPos - DimOffset(waveName, dim)) / DimDelta(waveName, dim)$

This expression calculates the number of an element in the dimension *dim* (p, q, r, or s). *ScaledDimPos* is the scaled position in that dimension (x, y, z, or t). *dim* is 0 for rows, 1 for columns, 2 for layers or 3 for chunks. Setting *dim* = 0 is equivalent to using x2pnt. The point number includes a fractional part; you may wish to use **ceil**, **round**, **trunc**, or **floor** to calculate an integer point number.

See Also

The functions **DimDelta**, and **DimOffset**.

For an explanation of waves and X scaling, see **Changing Dimension and Data Scaling** on page II-70.

xcsr

xcsr(cursorName [, graphNameStr])

The xcsr function returns the X value of the point which the named cursor (A through J) is on in the top or named graph.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The result is derived from the wave that the cursor is on, not from the X axis of the graph. If the wave is displayed as an XY pair, the X axis and the wave's X scaling will usually be different.

See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **qcsr**, **vcsr**, and **zcsr** functions.

XWaveName

XWaveName(graphNameStr, waveNameStr)

The XWaveName function returns a string containing the name of the wave supplying the X coordinates against which the named wave is displayed in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

XWaveName returns the null string ("") if the wave is not plotted versus an X wave.

For most uses, we recommend that you use **XWaveRefFromTrace** instead of WaveName. XWaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the X wave referred to in the graph has the same name as a different wave in the current

data folder. Likewise, if the named wave resides in a folder that is not the current data folder, you will not be able to refer to the named wave.

graphNameStr and *waveNameStr* are strings, *not* names.

Examples

```
Display ywave vs xwave           // XY graph
Print XWaveName("", "ywave")     // prints xwave
```

XWaveRefFromTrace

XWaveRefFromTrace(*graphNameStr*, *traceNameStr*)

The XWaveRefFromTrace function returns a wave reference to the wave supplying the X coordinates against which the named trace is displayed in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

XWaveRefFromTrace returns a null reference (see **WaveExists**) if the wave is not plotted versus an X wave.

graphNameStr and *traceNameStr* are strings, *not* names.

Examples

```
Display ywave vs xwave           // XY graph
Print XWaveRefFromTrace("", "ywave")[50] // prints value of xwave at point 50
```

For other commands related to waves and traces: **WaveRefIndexed**, **TraceNameToWaveRef**, **TraceNameList**, **CsrWaveRef**, and **CsrXWaveRef**.

For a description of traces: **ModifyGraph**.

For a discussion of contour traces see **All About Contour Traces** on page II-306.

For commands referencing other waves in a graph: **ImageNameList**, **ImageNameToWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

For a discussion of wave references, see **Wave Reference Functions** on page IV-143.

y

y

The y function returns the Y value for the current column of the destination wave when used in a multidimensional wave assignment statement. Y is the scaled column index whereas **q** is the column index itself.

Details

Unlike **x**, outside of a wave assignment statement, y does not act like a normal variable.

See Also

x, **z**, and **t** functions for other dimensions.

p, **q**, **r**, and **s** functions for the scaled indices.

z

z

The z function returns the Z value for the current layer of the destination wave when used in a multidimensional wave assignment statement. z is the scaled layer index whereas **r** is the layer index itself.

Details

Unlike **x**, outside of a wave assignment statement, z does not act like a normal variable.

See Also

x, **y**, and **t** functions for other dimensions.

p, **q**, **r**, and **s** functions for the scaled indices.

ZCSR**zcsr(cursorName [, graphNameStr])**

The zcsr function returns a Z value when the specified cursor is on a contour, image, or waterfall plot. Otherwise, it returns NaN.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Examples

```
Print zcsr(A)           // not zcsr("A")
Print zcsr(A,"Graph0")  // specifies the graph
```

See Also

The **Cursor** operation and the **CsrInfo**, **hcsr**, **pcsr**, **qcsr**, **vcscr**, and **xcscr** functions.

ZernikeR**zernikeR(n,m,r)**

The ZernikeR function returns the Zernike radial polynomials of degree n that contains no power of r that is less than m . Here m is even or odd according to whether n is even or odd, and r is in the range 0 to 1.

Note that the full circle polynomials are complex. For any angle t (theta), they are given by:

zernikeR(n,m,r)*exp(it).

 - pnt2x function V-428
 - rightx function V-469
 - Rotate operation III-257
 - SetScale operation V-499
 - x2pnt function V-666

X units

- changed by FFTs III-232
- changed by IFFTs III-233
- changing II-70, V-67
 - SetScale operation V-499
- default II-69

X values II-64–II-65

- (see also index values)
- can't enter in tables II-184
- clipping in subranges II-82
- conversion to point numbers V-666
- definition II-65
- in tables II-172, II-180
- in wave assignments II-80
- indexing II-80–II-81
- interpolation II-82
- pnt2x function V-428
- relation to point numbers II-65
- tag attached at III-53
- viewing in tables II-172
- x function V-665
- x2pnt function V-666

X waves

- CsrXWave function V-72
- CsrXWaveRef function V-72

x2pnt function V-666

Xcode IV-151

xcsr function V-666

XFUNCs (see external functions)

XLLoadWave XOP II-150

XOP Toolkit IV-151–IV-152

XOPs IV-151

XOPs (see external operations)

XOR

- bitwise operator IV-5–IV-6

XWaveName function V-666

XWaveRefFromTrace function IV-144, V-667

XY data

- areaXY function V-24
- converting to waveform data II-83, III-116
- definition I-3
- description of II-65
- faverageXY function V-137
- in curve fitting III-159, III-175

XYToWave1 user-defined function III-117

XYToWave2 user-defined function III-118

XYZ (color) conversions

- rgb2xyz V-261
- xyz2rgb V-264

XYZ data

- bounding sphere V-33
- converting to matrix II-300
- interpolation V-282, V-528

Y

y

- suffix in tables II-180

Y full scale

- default II-69

y function V-667

- in multidimensional waves II-92–II-93, II-95

Y scaling

- changing V-67
 - SetScale operation V-499
- CopyScales operation V-67
- SetScale operation V-499
- use in Axis Range tab II-227

Y units

- changing V-67
 - SetScale operation V-499
- default II-69

Y values

- lists of II-82
- y function V-667

Z

z function V-667

- in multidimensional waves II-92–II-93, II-95

Z scaling

- changing V-67
 - SetScale operation V-499
- CopyScales operation V-67
- SetScale operation V-499

Z units

- changing V-67
 - SetScale operation V-499

Z values

- z function V-667

zcsr function V-668

ZernikeR function V-668

zero end effect method III-257

zero line in graphs II-249

zero padding waves V-453

zeros of functions

- finding III-275–III-281
- FindRoots operation V-157
