Optimal Industry Development Strategy for Argentina

0. Executive Summary

In this report, we uncover the economic path Argentina went through during the period from 2013 to 2018. We include an additional analysis regarding the impact of COVID-19 on the country's development in 2021. Specifically, we dive into the topic through a macroeconomic overview of Argentina from the perspective of Gross Domestic Product (GDP) and Economic Complexity Index (ECI), which reflect countries' production capability and production structure, respectively. We find that during the period of our interest, Argentina demonstrated a high level of economic growth with an average annual GDP growth rate of 5.3%, concurrent with a decrease in economic complexity as compared with other major developed economies. Average annual GDP growth decreased to 4.06% between 2019 to 2021, and economic complexity decreased, again in line with other major developed economies.

The lack of progress during the period can be partially explained through analysis of the economic complexity structure of Argentina on an industry group level. The product classification system we adopt allows us to measure the realized development for various industry groups. We observe that Argentina consistently relied on developing the Machinery and Construction industry during the period, while its developed counterparts and emerging economies around the globe adopted much more complex and progressive paths. Regarding the post-COVID decline in economic complexity coupled with a higher GDP as observed in 2021, we determine that Argentina prioritized industries such as Services & Utilities in reaction to the higher global demand for such products in the midst of a pandemic.

Based on our analysis of the opportunity gain and a sensitivity analysis of major industry groups, Argentina can further its gains by prioritizing Energy and Drilling and Precious Stones. We further note that Argentina has a slightly mismatched development strategy that indicates a moderately high (compared to other developed countries) level of structural optimality on the complexity level, having an adjusted R-square of around 27.8%. A significant positive correlation exists between five-year GDP growth and the structural optimality index of an economy as we define and calculate, but Argentina still has a suboptimal growth experience as compared with fast-growing economies both on a regional scale and on a global scale. However, the country has the potential to further its economic gains through industrial structure optimization as suggested in the paper.

1. Report Overview

We aim to uncover the economic path Argentina went through during the period from 2013 to 2018 and the impact of COVID-19 on its economic development as observed in 2021. Specifically, we dive into the topic through a macroeconomic overview of Argentina from the perspective of Gross Domestic Product (GDP) and Economic Complexity Index (ECI), which reflect countries' production capability and production structure, respectively. We then analyze the industrial framework of Argentina during the period based on quantitative measures such as Product Complexity Index (PCI) and Product Family Complexity Index (PfCI), followed by a detailed analysis of how changes to this framework have matched with development strategies as quantitatively measured by opportunity gains on an industry-level. We conclude our report with macro-level results and predictions of Argentina, as deduced from regression models we have established on a global scale, which take into account countries' stances in their product space.

2. Macroeconomic Results

2.1 GDP Ranking and Changes

Figure 1 illustrates the time-series GDP results for Argentina and three of its peer countries (Uruguay, Paraguay, Costa Rica) from 2013-2018. Argentina, like other peer countries, has shown upwards growth in GDP over the years. Moreover, Argentina's GDP has grown at a faster rate than its peer countries. Argentina's average annual growth rate of 5.3% has been higher than its peers, which are 3.01%, 4.94% and 4.35% for Uruguay, Paraguay and Chile respectively.

Figure 1: GDP Comparison Among Peer Countries (2013 - 2018)

Figure 2 illustrates the time-series GDP results in 2019-2021. Similar to the other countries, Argentina displayed upward growth over the period, despite an observed decrease in GDP in 2020 due to the economic implications of COVID-19. Yet, it displayed a decrease of 0.73% in

average annual growth rate, down to 4.06%; meanwhile, Uruguay and Paraguay remained relatively stable at -0.59% and 1.15% respectively.

Figure 2: GDP Comparison Among Peer Countries (2019-2021)

2.2 ECI Ranking and Changes

The Economic Complexity Index (ECI), as defined by Ricardo Hausmann and Cesar Hidalgo in 2009 to explain the knowledge accumulated in a country's population, exhibits a similar growth pattern for Argentina. As illustrated in Figure 3 below, Argentina (-95.16% ECI change) exhibited a decrease in terms of its production capability from 2013 to 2018, which is different from Uruguay (-183.37%), Chile (-85.47%) and the Paraguay (8.67%). Ultimately, Argentina is among the weakest of the peer country set, as it displays the medium GDP growth rate and abysmal ECI change across the period.

Figure 3: ECI Comparison

Figure 4 offers a further comparison of GDP Growth and ECI over the time span from 2013 to 2018 for Argentina. The increase in GDP during the period from 2013 to 2018 is accompanied by a sharp decline in ECI. The results show that the economic growth experienced by Argentina during the period from 2013 to 2018 is not very consistent with the predictions by ECI and Argentina did not effectively make strides to develop a competitive product space that helps to accumulate complicated knowledge and technology. In order to provide a more concrete answer to why this has happened, we will dive into an analysis of Argentina production structure and its product space designs in the next few chapters.

Figure 4: GDP Growth and ECI (2013 - 2018)

Figure 5 compares GDP Growth and ECI between 2019 and 2021 for Argentina. The decrease followed by a slight increase in GDP growth during the period from 2019 to 2021 is paralleled by opposite changes in ECI. The COVID-19 pandemic in 2020 necessitated a prioritization of low complexity industries as demand for basic, essential products replaced that of higher-complexity, discretionary products. This explains the inconsistency in the relationship between GDP and ECI presented by Argentina over this period.

Figure 5: GDP Growth and ECI (2019 - 2021)

3. Production Analysis

3.1 Product Categorization

Our main data source in this research is the UN Comtrade Website (<https://comtrade.un.org>), which provides us with valuable information on countries' export values on an annual basis, including highly specific export data for more than 5000 categories of products. In order to have a holistic vision of the product space of a country, however, a level of categorization is required. Products in our data source are labeled from 010000-999999, with the first two-digits representing a general category to which the product belongs. Based on the 99 categories as extracted from the label, we further group the products into 18 most widely-accepted industries, as summarized in Table 1.

Note that the High-complexity Products industry group is not a distinct industry but rather an aggregated industry that encompasses the most complicated products from the most technologically-advanced industries (as measured by PCI). This industry serves as an indicator for us to quantitatively evaluate how well a country has performed in developing cutting-edge technologies and closing its technical gap with advanced economies, which has become a topic of wide concern today. Indeed, when we rank the 18 categories based on PfCI (an equivalent concept of PCI as calculated based on the 18 categorized product groups), the High-complexity Products industry has the highest PfCI among all industry groups.

Category	Description
Animals and By-products	All kinds of meat, livestock and related by-products
Vegetables, Fruits and Plants	All kinds of plants, edible vegetables and fruits
Food and Preparations	Edible preparations, raw cooking materials and appliances
Clothing and Accessories	All kinds of fabrics, filament, clothing and accessories
Textiles	All kinds of textile articles and related products
Wood Products	Book, paper and other elementary products related to wood
Metals	Mining of all sorts of raw Metals
Refined and Processed Stones	Refined or processed stone products such as pearl and ceramics
Energy Drilling and Mining	Mining industry for energy, minerals, stone materials, etc.
Daily Instruments	Basic daily instruments such as sport requisites, timing and measuring tools
Raw Manufacturing	Basic products made from plastic, rubber, leather, etc.
Chemical Manufacturing	Advanced chemical products and pharmaceutical products
Chemicals	Raw chemical materials and by-products
Machinery and Construction	Machinery and mechanical appliances, including electrical equipment
Transportation	Vehicles and locomotives including aircraft, ship, railway, etc.
Weapons	Explosives, arms and ammunition
Services and Utilities	Financial, business, legal, communication, travel Services and Utilities, etc.
High-complexity Products	Agglomeration of advanced products with highest PCIs

Table 1: Categorization of Products

We further observe a positive correlation between the GDP and the export of High-complexity Products. A higher adjusted R-square exists between GDP and High-complexity Products exports, indicating that more successful economics, as measured by GDP, tend to be those that

are capable of producing and exporting High-complexity Products as we define them. The Figure 3 and 4 show the OLS results in a universe of 107 and 21 typical countries respectively.

	High-complexity Products	Food and Preparations	Animals and By-products
Adj.R-squared	0.075	0.006	0.002
F-statistic	9.556	1.638	1.175

F-statistic	4.510	1.059	0.7542
No. Observations	21	21	21

Figure 4: OLS Regression Results of GDP against Volume of Percentage Exports

3.2 Realized Industry Development

Based on the product categorization aforementioned, we aim to capture Argentina's realized industry production strategy between 2013 and 2018 on a complexity level. In Hausmann and Hidalgo (2009), distance is defined to be a measure of how far a country is from a certain product not in its product space. We extend this concept to all product groups and quantify how technically equipped a country is to develop the corresponding product groups. In other words, the shorter the distance between a country and a product group, the more capable a country is in developing products within that group. Defining this net distance change as the Realized Industry Development (RID), our export data allow us to calculate and compare RID of Argentina and the 18 product groups in 2018 and 2021 through subtraction, where a positive RID indicates a shortening of the distance (i.e., advancement of the industry), and a negative RID indicates the reverse.

	Category	RID
5	Chemical Manufacturing	-0.025935
3	Energy Drilling and Mining	-0.012947
17	Services and Utilities	-0.008043
8	Clothing and Accessories	-0.003616
1	Vegetables, Fruits and Plants	-0.002324
2	Food and Preparations	-0.000724
9	Textile	0.002362
0	Animals and By-products	0.007411
15	Precious Stones	0.021800
7	Wood Products	0.022421
10	Metals	0.030564
13	Weapons	0.034790
14	Daily Instruments	0.037479
6	Raw Manufacturing	0.047513
4	Chemicals	0.064976
12	Transportation	0.068862
11	Machinery and Construction	0.075555
16	High-complexity Products	0.081257

Table 2: Realized Industry Development (RID) of Argentina (2013 - 2018)

Between 2013 and 2018, Argentina shows advancement in more than half of the product groups, with negative RIDs pertaining mostly to low-complexity industries. However, Argentina demonstrates a highly egressive trend in ECI between 2019 and 2021, as many previously positive RID industries change to negative, with the exception of Service and Utilities.

	Category	RID

4	Raw Manufacturing	Textile	Machinery and Construction
5	Weapons	Raw Manufacturing	High-complexity Products

Table 4d: RID Comparison across Emerging Economies (2021)

Table 4 further examines Argentina's development strategy against those of emerging economies on a global scale. Reasonably, emerging economies such as China, South Korea, Singapore and India have devoted the majority of their efforts into intermediate industry groups while developed economies such as Argentina should have relied more on advanced industry groups. This trend holds true in general, regardless of the continent or the time period, and serves as an indicator for which phase of development a country is currently in as evaluated from its production strategy. Based on this standard, Argentina is indeed adopting a moderate but slightly out-of-phase strategy that seeks development in industry groups with a lower level of complexity than it should.

4. Product Space Design

4.1 Suggested Development Vector

As aforementioned, distance gives us an idea of how far each new product is from a country's current mix of exports. As defined in Hausmann and Hidalgo (2009), distance is "the weighted proportion of products connected to goods p that country c is not exporting, i.e., $MCP=0$." Based on this definition, the distance between a country and any product that the country is currently exporting (i.e., the country is a significant exporter in the product as compared to global average) is zero. Similarly, opportunity gain quantifies the contribution of a new product in terms of opening up the doors to more and more complex products. Intuitively, a product that a country is currently exporting (i.e., $MCP=1$) has an opportunity gain of zero. And unreasonable investment on certain product p would lead to a relative decrement in export of more profitable products, and therefore lead to a negative opportunity gain of product p . The opportunity gain is not the only estimator of a country's level of economic development. However, among countries

with comparable economics strength, those having higher ECI, or in other words, more reasonable economics structures are often in better shape.

Table 5: SDV of Argentina and Comparable Countries 2013(up), 2018(down)

We define the ranking of opportunity gain for a country c , as the Suggested Development Vector (SDV) of c . Table 5 and 6 summarize how the SDV of Argentina compares with a selected group of comparable and leading economies in the world, with the industry groups ranked in decreasing order of significance. Dark blue indicates positive opportunity gain, light blue indicates zero opportunity gains, and white indicates negative opportunity gains. The result shows that leading countries barely have any industries with positive opportunity gain. In other words, those countries are already in the most stable and efficient economic structure. Without

the necessity of economic transition, those countries merely need to maintain a steady and balanced economic development. In contrast, developing countries have nearly half of industries with positive opportunity gain, and share common interests in industrial manufacturing and High-complexity Products industries. It can be concluded that Argentina shares the characters of developing countries, with a balanced economics structure that leans towards intermediate-level industries. We focus on SDV results for 2018 because they give the most accurate snapshot of complexity for global comparison in the absence of the irregular effects of the COVID-19 pandemic observed in 2021.

Table 6: SDV of Other Typical Countries 2013

4.2 Budgeted Industry Development Strategy and Interpretation

The optimal budgeted industry development strategy aims to solve the most efficient allocations under the budgeted constraint of different situations of heuristic total export growth. In order to obtain such an allocation portfolio, we formulate an optimization problem as the following:

$$\begin{aligned}
 & \max_{x \in \mathbf{R}^{|P|}} \left(\frac{k(x) - \langle k(x) \rangle}{stdev(k(x))} \right)_C \\
 & \text{Subject to} \\
 & \sum_{p \in P} x_p \leq B \\
 & x \succeq 0
 \end{aligned}$$

where $k(x)$ is the second largest eigenvector of M_{CC} , after adding x to the original export vector, C is the country that we are interested in, P is the product space, B is the heuristic budget.

If we can solve this problem, then we can know what the largest ECI that a country can improve to. Accordingly, the optimal solution x^* that we obtain here is exactly our optimal allocation. However, the biggest problem is that the objective function is not convex. Therefore, we cannot

apply the classical tools for convex optimization on this problem. In order to solve this problem, our idea is to use greedy algorithm. The way that we apply greedy algorithm is that firstly we separate the total budget into k equal parts, and then for the first equal part we try to search for the product that can optimize our objective function by iterating through each $p \in P$. After we find the optimal product p for this equal part, we add the amount back to the export value of this product p and update the ECI for this country. If we observe that ECI does not change after iterating all the products, then we can add up one more equal part to invest. Until we find there is an ECI increment, we add the amount now to that product. The rest equal parts can be done in the same way.

However, as is known to all, greedy algorithm is a kind of local search algorithm, which is pretty possible to run into a local minimum. Therefore, for local search algorithms, one typical way is to keep it away from the local minimum is to enhance the vision of the algorithm by looking more steps forward. In our setting, whenever we obtain an increment of ECI, we mark down the required amount of export growth. Simultaneously, we continue searching for the next ECI increment point, compare the ratios of these two possibilities and pick the largest one. The ratio is defined as the following:

$$Ratio(p) = \frac{ECI_p - ECI_0}{||x_p - x_0||_1}$$

where ECI_p is just the ECI of the country after adding some amount of export increment to product p , which is exactly the amount that is able to make ECI change. Also, we can express it in the way of $||x_p - x_0||_1$.

In this way, we can obtain a further sighted greedy algorithm. Also, the number of parts that we would like to separate the budget into also matters. In order to solve this problem, we added a stabilizer on top of the enhanced greedy algorithm, by running the algorithm for different numbers of parts and selecting the portfolio with the largest ECI increment and most complex economic structure.

Besides, it is quite common that there is a surplus for the budget. To deal with the surplus, we just add it to the product which needs the least amount of dollar to make $M_{cp} = 1$, (i.e., the smallest amount of required export increase).

Interpretation:

For the purpose of a clear explanation of the line charts, we try to label all the products in Table 7. Please refer to this table when trying to understand the investment trajectories in the line charts.

Label	Product Names
-------	---------------

1	Animals and By-products
2	Vegetables, Fruits and Plants
3	Food and Preparations
4	Energy Drilling and Mining
5	Chemicals
6	Chemical Manufacturing
7	Raw Manufacturing
8	Wood Products
9	Clothing and Accessories
10	Textile
11	Metals
12	Machinery and Construction
13	Transportation
14	Weapons
15	Daily Instruments
16	Precious Stones
17	High-complexity Products
18	Services and Utilities

Table 7: Products Labeling

Below is the economic panel for Argentina in 2013. We can see that for different percentages of heuristic total export growth, the ECIs of Argentina have different amounts of increments. Overall, 5 and 10 percent export growth result in a similar ECI improvement pattern, which starts from around -0.02 and ends at around 0.69. However, 15 and 20 percent export growth are able to result in obvious ECI improvement trajectories. For both 15 and 20 percent growth budget, the ECI of Argentina is able to end at around 1.1.

For the case of 5 and 10 percent export growth, chemicals, wood products and transportation account for most of the portfolio. For 10 percent export growth, a higher weighting is derived from wood products. For the case of 15 and 20 percent increment budgets, we realize that the development trajectories are in a similar pattern except that there are a few additional steps when

there are more budgets. Unlike the previous two cases, the solutions suggest that Argentina should invest more on Machinery and Construction and Weapons. This makes sense because with more budgets, a country should definitely focus more on the development of high-end product spaces. A more detailed numerical representation of the portfolio is shown in Table 8.

Argentina ECI Growth Optimization Result

Figure 5: Greedy Based ECI Improvement Results of Argentina in 2013 with Different Budgets

Argentina (2013)				
Original ECI	-0.02			
Heuristic Export Growth	5%	10%	15%	20%
Chemicals	1.25E+09	1.25E+09	0.00E+00	1.25E+09
Wood Products	1.72E+09	6.25E+09	2.34E+09	0.00E+00
Textile	3.13E+08	3.13E+08	4.69E+08	6.25E+08
Machinery and Construction	0.00E+00	0.00E+00	7.50E+09	8.13E+09
Transportation	1.41E+09	1.56E+09	3.75E+09	3.75E+09
Weapons	0.00E+00	0.00E+00	0.00E+00	5.00E+09
Increased ECI	0.69	0.69	1.10	1.10

Table 8: Portfolio of Argentina in 2013

For further suggestions on Argentina's development in the future. We also offer the optimization result of Argentina based on export data in 2018. Below is the economic panel for Argentina in 2018. We can see that the ECI improvement trajectories are lower than in the 2013 case, the improvements in 5 and 10 percent export growth are lower, and the ones in 15 and 20 are also

lower. Another striking difference in the growth optimization result is that for a 10 percent export growth, there is a greater emphasis on Machinery and construction, which falls in line with higher budget of investment cases. However, as seen in the 2013 case, for 15 or 20 percent of growth, the portfolios are much more diverse than the previous two cases. In detail, industries like Daily Instruments and Chemical manufacturing contribute a lot more in ECI increments. A more detailed numerical representation of the portfolio is shown in Table 9.

Argentina ECI Growth Optimization Result

Argentina ECI Increment

Increased ECI	-0.29	0.09	0.45	0.62

Table 9: Portfolio of Argentina in 2018

4.3 Sensitivity Analysis and Contingency Strategy

In the following section our broad aim is to understand how sensitive Argentina is to changes in export in various industries. While the Economic Complexity Index has been shown to contain valuable information about the economic strength/capacity of a country, little has been said as to the stability of the measure itself. We seek to uncover the main drivers of stability under a country's ECI score and better understand longer-term projections for ECI growth. Additionally, gaining an intuition on the industries that are bolstering an economy and the industries that offer the greatest return per unit of investment is best done through visualization of industry specific sensitivity. To this end, we have developed two categories of sensitivity analysis.

ECI Sensitivity Graph

Firstly, in order to assess the effect particular industries have on each respective country, we developed ECI Sensitivity graphs. We use shocking methodology to increment or decrement an industry's export level by a certain percentage and recalculate the ECI all else being equal. While freezing the export dynamics of the rest of the world and enacting an instantaneous shock in export for a particular industry and country may not reflect real-life dynamics, what it does offer us is an understanding of a country's level of dependency on an industry in the context of ECI. The shocking is done in small percentage increments in order to smooth out the resulting curve. Additionally, a recurring theme one will see is that for most industries, a breaking point occurs where the ECI either jumps upwards or downwards, creating a hockey stick shape rather than a linear trend. While the inflection point may not be accurate in the context of real life, comparing the various inflection points across industries can give us valuable insight.

The graphs are formulated as follows: There are four ECI Sensitivity graphs. The first two represent data from 2018. The first chart shows positive shocks in which export numbers are shocked upwards per industry. The X-axis is in terms of percentage shock per current dollar value of export. The Y-axis is the recalculated ECI level post-shocking. The second chart follows the same format except the X-axis represents negative shocking. In other words, exports for each industry are decremented and the ECI is accordingly recomputed. The final two sensitivity graphs show the same results using 2013 data. Below is an example of an ECI sensitivity graph.

Example 2018 (Incremental ECI Sensitivity)

SDV sensitivity

Secondly, we analyze the sensitivity of the SDV to changes in export levels. The goal is to understand how export level changes for a particular industry can affect the marginal opportunity gain for other industries. We will be using specifically High Complexity Products and Food and Preparations as our base industries. We will be increasing or decreasing the absolute export level in both of these industries and observing the effects on the SDV.

When the opportunity gain of an industry is negative, the SDV sensitivity approximates how an over-development of the industry jeopardizes the economic structure of a country. When the opportunity gain of the industry is zero, the SDV sensitivity determines whether the further development of the industry shapes the country with a better economic structure and predicts how the SDV would change accordingly. Specifically, as we reduce the export of such an industry to 25%-50% of its original value, a few other industries originally with negative opportunity gain could likely become profitable.

Similar to the ECI sensitivity graphs above, we will be shocking the export of High Complexity Products and Food and Preparations in small percentage increments. A new SDV, represented by a new column in the charts, is recorded only when a certain level of shock changes the structure of the SDV. In effect we are incrementing or decrementing export levels of two industries until the marginal opportunity gain of any industry changes in category (positive, negative, or neutral). Below is an example of a SDV Sensitivity chart with Positive Shocking. Industries with positive marginal opportunity gain are colored blue, neutral is colored white and negative is colored red.

Contingency Plan

The Contingency Plan aims to present a set of solutions with respect to upheavals in different industries. Instead of compensating for the declining production directly, the best strategy is to develop those incipiently profitable industries. In this manner, we can derive the contingency strategy for countries to deal with possible abrupt declines of crucial industries. In some cases, the SDV remains unchanged even when a zero-opportunity-gain industry declines to its 20% in terms of export. We can then conclude the industry is not indispensable to the country. As a clarification, the three consecutive N/As means that the country doesn't even need to respond to a collapse in the industry. Countries tend to have distinct solutions to the up and down of the same industry. To create the contingency strategy table we decrease the export level for each industry in the country's current production space by 60% respectively. The three highest ranking industries in the new SDV are then returned.

Example Contingency Strategy 2018

4.3 Sensitivity Analysis Results and Interpretation

Below is Argentina's 2018 ECI Sensitivity Charts. Firstly in the positive chart, we notice immediately that increases in High Complexity Products and Transportation lead to an uptrend in ECI. Chemical Manufacturing offers the best ECI growth per unit of export increase. Most other industries tend to not greatly affect the ECI level making it fairly clear which industry to pursue.

Next we consider Argentina's 2018 Negative Shock chart. We see that Argentina's ECI is highly sensitive to multiple industry groups, including Animals and By-products, Vegetables, Fruits & Plants, Food and Preparations and Services & Utilities. Large decreases in all of the aforementioned industries seems to greatly increase the ECI score. These industries are important industries for Argentina's economy and thus the results that are reflected in the chart may be suggesting that there is another industry that could be very beneficial for Argentina that is far in proximity from them.

Argentina 2018 (Incremental ECI Sensitivity)

Argentina 2018 (Decremental ECI Sensitivity)

Next we consider the 2013 ECI Sensitivity graphs. We see that in the positive shocking case, the landscape of ECI sensitivity has not altered significantly over the five year period. High complexity products and Transportation seem to offer the best ECI growth prospects. However, there are more industry groups which negatively impact ECI, namely Animals and By-Products and Food and Preparations. In the decremental scenario, we see a common trend of a decrease in Food and Preparations improving ECI, but we also see that decreasing industries like Chemical Manufacturing and Services & Utilities does negatively impact the ECI, suggesting that they may indeed be important to the economy.

Argentina (Postive Shocking)

Argentina 2013 (Incremental ECI Sensitivity)

Argentina (Negative Shocking)

Argentina 2013 (Decremental ECI Sensitivity)

Below we see the SDV sensitivity charts for High-Complexity Products. We see that after increasing the export of High-Complexity Products by 200% leads to an additional gain in ECI as we open more positive opportunity-gain industries. However, this is a large jump to achieve, and we see no further gains past this point.

In the negative SDV chart, we see that as we decrease the export of High-Complexity products, the ECI does also increase, to an even greater extent, as we see one additional industry become opportunity gain-neutral.

Concerning Food and Preparations, Argentina seems to experience an increase in ECI and a gain in the number of Opportunity-gain positive industries after a 100% increase in this export. However, we see much higher gains when we decrease Food and Preparations exports – at just a 18% decrease, ECI jumps to -0.568, and this trend continues as we go to a 96% decrease.

Argentina Contingency Strategy

Based on Argentina's RID for 2021, we note that the contingency strategy recommended by our algorithm in 2018 is mirrored by Argentina's development strategy over the course of the pandemic. As such, it supports the reasoning behind Argentina's increase in GDP between 2019 and 2021.

5. Macro-level Predictions

5.1 Structural Optimality Index

Indeed, such choice of prioritization has proven to be a significant factor in deciding the economic outcomes of countries. In order to quantitatively evaluate how effective our development strategies are and how deviations from the suggested developmental path will lead to suboptimal growth results, we define the measure – Structural Optimality Index (SOI) – on a country level as the Adjusted R-Square obtained from regressing the country's realized industry development over the suggested development strategy. Both strategies are quantified in nature, with the realized development represented by export increase in every major industry group and the suggested development strategy represented by the opportunity gains of developing the corresponding industry groups as calculated in previous sections. The adjusted R-square from the regression thus provides us with a quantified measure of how the development path adopted by the country has fitted with/differed from calculations on a complexity level.

After obtaining this measure for all countries in our database, we further regress countries' five-year economic growth, which is defined as the percent increase in GDP (USD), over their SOI. Figure 6 illustrates the regression output, which shows a strong positive correlation between countries' SOI and their five-year GDP growth, significant at the 1% level and achieving an adjusted R^2 of 4.5%. In other words, the more a country develops as suggested by calculations on a complexity level, the better economic outcomes it achieves.

Table 18: OLS Regression Results	
Dep. Variable: GDP	F-Statistic: 5.963
R²: 0.054	Prob (F-Stat): 0.0163
Adj R²: 0.045	No. Observations: 106

Figure 2: Regression of Five-year GDP Growth over SOI

5.2 SOI of Argentina and Its Implications

Argentina for instance, has a high level of structural optimality as compared with its developed peers. As the regression in Figure 7 suggests (the orange curve represents export increase and the blue curve stands for opportunity gain of the corresponding industry), Argentina demonstrates a high level of correlation with the suggested developmental path, having an adjusted R-square of around 27.8%. Argentina ranks in the top quartile among all countries in terms of SOI and has made a medium rate of economic progress in line its developed peers from 2013 to 2018 with a 5-year GDP growth rate of 15.6%, which is consistent with the regression result in Figure 6. This is in direct contrast to other developed economies such as Japan, where there is low SOI of around -5.7% and a corresponding GDP growth of 9.05% from 2013 to 2018, making it a much faster developing economy during the period. In sum, Argentina's mixed economic progress from 2013 to 2018 can be at least partially explained by a development strategy that demonstrates a strong level of matches with our suggested developmental path. In specific, Argentina invested heavily in the Machinery and Construction industry, while it should have focused more on more industry groups such as Precious Stones and Energy & Drilling. That

being said, it stayed fairly in line with our expectations in the Raw Manufacturing and Metals industry.

Figure 7: SOI of Argentina (2013-2018)

In 2021, Argentina ranks in the second quartile among all countries in terms of SOI. Progress is slow on a global scale during this period, but Argentina demonstrates a greater ability to adjust to negative economic shocks by improving SOI and increasing GDP growth.

Figure 8: SOI of Argentina (2019 - 2021)

6. Concluding Remarks

In conclusion, Argentina has demonstrated a strong level of economic growth in terms of annual GDP increase during the period from 2013 to 2018, concurrent with a relative increase in economic complexity as compared with other major developed economies. In 2021, the economic effects of the COVID-19 pandemic can be seen in Argentina's regression in terms of economic complexity despite a considerable increase in GDP.

The progress during the period, we believe, can be partially explained through analysis of the economic and product complexity structure of Argentina on the industry group level. The product classification system we adopt allows us to measure the realized industry development for various industry groups and to observe that Argentina consistently relied on developing the Machinery & Construction industry during the period, while its developed counterparts and emerging economies around the globe have adopted much more complex and progressive paths. In 2021, the mixed progress is a result of global demand for basic, low-complexity products, which Argentina positions itself to meet. As such, its ECI decreases, but its GDP increases at a faster rate, in average, than its developed counterparts.

Based on our analysis of the opportunity gain and a sensitivity analysis of major industry groups, Argentina can further its gains by prioritizing Energy and drilling and Precious Stones. We further note that Argentina has a slightly mismatched development strategy that indicates a moderately high (compared to other developed countries) level of structural optimality on the complexity level, having an adjusted R-square of around 27.8%. Since a significant positive correlation exists between five-year GDP growth and the structural optimality index of an economy as we define and calculate, Argentina, however, still has a suboptimal growth experience as compared with fast-growing economies both on a regional scale and on a global scale, and has the potential to further its economic gains through industrial structure optimization as suggested in the paper.
