Optimal Industry Development Strategy for Canada

0. Executive Summary

In this report, we aim to uncover the economic path Canada went through during the period from 2013 to 2018. We include an additional analysis regarding the impact of COVID-19 on the country's development in 2021. Specifically, we dive into the topic through a macroeconomic overview of Canada from the perspective of Gross Domestic Product (GDP) and Economic Complexity Index (ECI), which reflect countries' production capability and production structure, respectively. We find that during the period of our interest, Canada demonstrated a moderate level of economic growth with an average annual GDP growth rate of 2.36%, concurrent with a decrease in economic complexity as compared with other major developed economies. Average annual GDP growth increased to 5.15% between 2019 to 2021, but economic complexity decreased, a trend that occurred with some but not all similar countries.

The lack of progress during the period, we believe, can be partially explained through analysis of the economic and product complexity structure of Canada on the industry group level. The product classification system we adopt allows us to measure the realized industry development for various industry groups and to observe that Canada consistently relied on developing the Transportation industry during the period, while its developed counterparts and emerging economies around the globe have adopted much more complex and progressive paths. Regarding the post-COVID decline in economic complexity coupled with a higher GDP as observed in 2021, we determine that Canada prioritized basic, low complexity industries such as Food and Preparations and Daily Instruments in reaction to the higher global demand for such products in the midst of a pandemic.

Based on our analysis of the opportunity gain and a sensitivity analysis of major industry groups, Canada can further its gains by prioritizing High Complexity Products, Transportation, and Machinery and Construction. We further note that Canada has a slightly mismatched development strategy that indicates a moderately high (compared to other developed countries) level of structural optimality on the complexity level, having an adjusted R-square of around 19.5%. Since a significant positive correlation exists between five-year GDP growth and the structural optimality index of an economy as we define and calculate, Canada has a comparable growth experience with fast-growing economies both on a regional scale and on a global scale, and also has the potential to further its economic gains through industrial structure optimization as suggested in the paper.

1. Report Overview

In this report, we aim to uncover the economic path Canada went through during the period from 2013 to 2018, and the impact of COVID-19 on its economic development as observed in 2021. Specifically, we dive into the topic through a macroeconomic overview of Canada from the perspective of Gross Domestic Product (GDP) and Economic Complexity Index (ECI), which reflect countries' production capability and production structure, respectively. We then analyze the industrial framework and changes of Canada during the period based on quantitative measures such as Product Complexity Index (PCI) and Product Family Complexity Index (PfCI), followed by a detailed analysis of how such changes have matched with development strategies as quantitatively measured by opportunity gains on an industry-level. We conclude our report with macro-level results and predictions of Canada, as deduced from regression models we have established on a global scale, which take into account countries' stances in their product space.

2. Macroeconomic Results

2.1 GDP Ranking and Changes

Figure 1 illustrates the time-series GDP results for Canada and three of its peer countries (the UK, Mexico, Australia) from 2013-2018. In contrast to the other countries, which generally displayed either constant or upwards growth over all years, Canada had a noticeable dip in GDP from 2014-2015. Additionally, Canada's average annual growth rate of 2.36% over the five-year period is clearly lower than its peers, which are 3.03%, 3.29%, and 3.36% for the UK, Mexico, and Australia respectively.

Figure 1: GDP Comparison Among Peer Countries (2013 - 2018)

Figure 2 illustrates the time-series GDP results in 2019-2021. Similar to the other countries, Canada displayed upward growth over the period, despite an observed decrease in GDP in 2020 due to the economic implications of COVID-19. Yet, it displayed a greater increase of 0.73% in

average annual growth rate, up to 5.15%; whereas Australia only increased 0.10%, up to 3.86%, and Mexico decreased 0.78%, down to 1.53%.

Figure 2: GDP Comparison Among Leading Economies (2019-2021)

2.2 ECI Ranking and Changes

The Economic Complexity Index (ECI), as defined by Ricardo Hausmann and Cesar Hidalgo in 2009 to explain the knowledge accumulated in a country's population, exhibits a similar growth pattern for Canada. As illustrated in Figure 3 below, Canada (-36.98% ECI change) exhibited a decrease in terms of its production capability from 2013 to 2018, which is similar to Australia (-29.46%), but different from Mexico (-8.2%) and the UK (41.53%). Ultimately, Canada is the weakest of the peer country set, as it displays the lowest GDP growth rate and ECI change across the period.

Figure 3: ECI Comparison (2013 - 2018)

However, as shown in Figure 4, Canada exhibits a significant decrease in production capability from 2019 to 2021. Its peers also experienced comparable decreases in production capability over the period, as marked by a sharp decline following 2020.

Figure 4: ECI Comparison (2019 - 2021)

Figure 5 offers a further comparison of GDP Growth and ECI over the time span from 2013 to 2018 for Canada. The increase in GDP during the period from 2013 to 2018 is accompanied by a sharp decline in ECI. The results show that the economic growth experienced by Canada during the period from 2013 to 2018 is not very consistent with the predictions by ECI and Canada did not effectively make strides to develop a competitive product space that helps to accumulate complicated knowledge and technology. In order to provide a more concrete answer to why this has happened, we will dive into an analysis of Canada's production structure and its product space designs in the next few chapters.

Figure 5: GDP Growth and ECI (2013 - 2018)

Figure 6 compares GDP Growth and ECI between 2019 and 2021 for Canada. The decrease followed by a sharp increase in GDP growth during the period from 2019 to 2021 is paralleled

by opposite changes in ECI. The COVID-19 pandemic in 2020 necessitated a prioritization of low complexity industries as demand for basic, essential products replaced that of higher-complexity, discretionary products. This explains the inconsistency in the relationship between GDP and ECI presented by Canada over this period.

Figure 6: GDP and ECI (2019-2021)

3. Production Analysis

3.1 Product Categorization

Our main data source in this research is the UN Comtrade Website (<https://comtrade.un.org>), which provides us with valuable information on countries' export values on an annual basis, including highly specific export data for more than 5000 categories of products. In order to have a holistic vision of the product space of a country, however, a level of categorization is required. Products in our data source are labelled from 010000-999999, with the first two-digits representing a general category to which the product belongs. Based on the 99 categories as extracted from the label, we further group the products into 18 most widely-accepted industries, as summarized in Table 1.

Note that the High-complexity Products industry group is not a distinct industry but rather an aggregated industry that encompasses the most complicated products from the most technologically-advanced industries (as measured by PCI). This industry serves as an indicator for us to quantitatively evaluate how well a country has performed in developing cutting-edge technologies and closing its technical gap with advanced economies, which has become a topic of wide concern today. Indeed, when we rank the 18 categories based on PfCI (an equivalent concept of PCI as calculated based on the 18 categorized product groups), the High-complexity Products industry has the highest PfCI among all industry groups.

Category	Description
Animals and By-products	All kinds of meat, livestock and related by-products
Vegetables, Fruits and Plants	All kinds of plants, edible vegetables and fruits
Food and Preparations	Edible preparations, raw cooking materials and appliances
Clothing and Accessories	All kinds of fabrics, filament, clothing and accessories

Textiles	All kinds of textile articles and related products
Wood Products	Book, paper and other elementary products related to wood
Metals	Mining of all sorts of raw Metals
Refined and Processed Stones	Refined or processed stone products such as pearl and ceramics
Energy Drilling and Mining	Mining industry for energy, minerals, stone materials, etc.
Daily Instruments	Basic daily instruments such as sport requisites, timing and measuring tools
Raw Manufacturing	Basic products made from plastic, rubber, leather, etc.
Chemical Manufacturing	Advanced chemical products and pharmaceutical products
Chemicals	Raw chemical materials and by-products
Machinery and Construction	Machinery and mechanical appliances, including electrical equipment
Transportation	Vehicles and locomotives including aircraft, ship, railway, etc.
Weapons	Explosives, arms and ammunition
Services and Utilities	Financial, business, legal, communication, travel Services and Utilities, etc.
High-complexity Products	Agglomeration of advanced products with highest PCIs

Table 1: Categorization of Products

We further observe a positive correlation between the GDP and the export of High-complexity Products. A higher adjusted R-square exists between GDP and High-complexity Products exports, indicating that more successful economics, as measured by GDP, tend to be those that are capable of producing and exporting High-complexity Products as we define them. The Figure 3 and 4 show the OLS results in a universe of 107 and 21 typical countries respectively.

	High-complexity Products	Food and Preparations	Animals and By-products
Adj.R-squared	0.075	0.006	0.002
F-statistic	9.556	1.638	1.175

F-statistic	4.510	1.059	0.7542
No. Observations	21	21	21

Figure 4: OLS Regression Results of GDP against Volume of Percentage Exports

3.2 Realized Industry Development

Based on the product categorization aforementioned, we aim to capture Canada's realized industry production strategy between 2013 and 2018 on a complexity level. In Hausmann and Hidalgo (2009), distance is defined to be a measure of how far a country is from a certain product not in its product space. We extend this concept to all product groups and quantify how technically equipped a country is to develop the corresponding product groups. In other words,

the shorter the distance between a country and a product group, the more capable a country is in developing products within that group. Defining this net distance change as the Realized Industry Development (RID), our export data allow us to calculate and compare RID of Canada and the 18 product groups in 2018 and 2021 through subtraction, where a positive RID indicates a shortening of the distance (i.e., advancement of the industry), and a negative RID indicates the reverse.

Category	RID
Chemical Manufacturing	-0.073082
Metals	-0.070972
Clothing and Accessories	-0.069591
Weapons	-0.064581

10	Metals	-0.000893
16	High-complexity Products	-0.000840
15	Precious Stones	0.011148
11	Machinery and Construction	0.014859
17	Services and Utilities	0.015551

Table 3: Realized Industry Development (RID) of Canada (2019-2021)

Between 2013 and 2018, Canada shows advancement in only one of the product groups. However, Canada demonstrates a progressive trend in ECI between 2019 and 2021, as while most industries continue to have slightly negative RID's, a couple industries switch from negative to positive RID's.

3.3 Regional and Global Comparison

Table 3 and 4 below summarize how the production strategy adopted by Canada compares with leading economies and a selected group of emerging economies in the world, as measured in RID.

Ranking	France	US	Germany
1	High-complexity Products	Services and Utilities	High-complexity Products
2	Chemical Manufacturing	Weapons	Transportation
3	Daily Instruments	Raw Manufacturing	Wood Products
4	Animals and By-products	Precious Stones	Metals

3	Transportation	Transportation	Transportation
4	Raw Manufacturing	Textile	Machinery and Construction
5	Weapons	Raw Manufacturing	High-complexity Products

Table 4d: RID Comparison across Emerging Economies (2021)

Table 4 further examines Canada's development strategy against those of emerging economies on a global scale. Reasonably, emerging economies such as China, South Korea, Singapore and India have devoted the majority of their efforts into intermediate industry groups while developed economies such as Canada should have relied more on advanced industry groups. This trend holds true in general, regardless of the continent or the time period, and serves as an indicator for which phase of development a country is currently in as evaluated from its production strategy. Based on this standard, Canada is indeed adopting a moderate but slightly out-of-phase strategy that seeks development in industry groups with a lower level of complexity than it should.

4. Product Space Design

4.1 Suggested Development Vector

As aforementioned, distance gives us an idea of how far each new product is from a country's current mix of exports. As defined in Hausmann and Hidalgo (2009), distance is "the weighted proportion of products connected to goods p that country c is not exporting, i.e., $MCP=0$." Based on this definition, the distance between a country and any product that the country is currently exporting (i.e., the country is a significant exporter in the product as compared to global average) is zero. Similarly, opportunity gain quantifies the contribution of a new product in terms of opening up the doors to more and more complex products. Intuitively, a product that a country is currently exporting (i.e., $MCP=1$) has an opportunity gain of zero. And unreasonable investment on certain product p would lead to a relative decrement in export of more profitable products, and therefore lead to a negative opportunity gain of product p . The opportunity gain is not the only estimator of a country's level of economic development. However, among countries

with comparable economics strength, those having higher ECI, or in other words, more reasonable economics structures are often in better shape.

Ranking	Singapore	Canada	Japan	Germany

Table 5: SDV of High E_fCI Countries 2013(up), 2018(down)

We define the ranking of opportunity gain for a country c , as the Suggested Development Vector (SDV) of c . Table 5 and 6 summarize how the SDV of Brazil compares with a selected group of comparable and leading economies in the world, with the industry groups ranked in decreasing order of significance. Dark blue indicates positive opportunity gain, light blue indicates zero opportunity gains, and white indicates negative opportunity gains. The result shows that leading countries barely have any industries with positive opportunity gain. In other words, those countries are already in the most stable and efficient economic structure. Without the necessity of economic transition, those countries merely need to maintain a steady and balanced economic development. In contrast, developing countries have nearly half of industries with positive opportunity gain, and share common interests in industrial manufacturing and High-complexity Products industries. It can be concluded that Canada shares the characters of developing countries, with a balanced economics structure that leans towards intermediate-level industries. We focus on SDV results for 2018 because they give the most accurate snapshot of complexity

for global comparison in the absence of the irregular effects of the COVID-19 pandemic observed in 2021.

Ranking	Algeria	Italy	USA	United Arab Emirates

Table 6: SDV of Other Typical Countries 2013

4.2 Budgeted Industry Development Strategy and Interpretation

The optimal budgeted industry development strategy aims to solve the most efficient allocations under the budgeted constraint of different situations of heuristic total export growth. In order to obtain such an allocation portfolio, we formulate an optimization problem as the following:

$$\begin{aligned}
 & \text{Max}_{x \in \mathbf{R}^{|P|}} \left(\frac{k(x) - \langle k(x) \rangle}{stdev(k(x))} \right)_C \\
 & \text{Subject to} \\
 & \sum_{p \in P} x_p \leq B \\
 & x \succcurlyeq 0
 \end{aligned}$$

where $k(x)$ is the second largest eigenvector of $M_{CC'}$ after adding x to the original export vector, C is the country that we are interested in, P is the product space, B is the heuristic budget.

If we can solve this problem, then we can know what the largest ECI that a country can improve to. Accordingly, the optimal solution x^* that we obtain here is exactly our optimal allocation. However, the biggest problem is that the objective function is not convex. Therefore, we cannot apply the classical tools for convex optimization on this problem. In order to solve this problem, our idea is to use greedy algorithm. The way that we apply greedy algorithm is that firstly we separate the total budget into k equal parts, and then for the first equal part we try to search for the product that can optimize our objective function by iterating through each $p \in P$. After we find the optimal product p for this equal part, we add the amount back to the export value of this product p and update the ECI for this country. If we observe that ECI does not change after

iterating all the products, then we can add up one more equal part to invest. Until we find there is an ECI increment, we add the amount now to that product. The rest equal parts can be done in the same way.

However, as is known to all, greedy algorithm is a kind of local search algorithm, which is pretty possible to run into a local minimum. Therefore, for local search algorithms, one typical way is to keep it away from the local minimum is to enhance the vision of the algorithm by looking more steps forward. In our setting, whenever we obtain an increment of ECI, we mark down the required amount of export growth. Simultaneously, we continue searching for the next ECI increment point, compare the ratios of these two possibilities and pick the largest one. The ratio is defined as the following:

$$Ratio(p) = \frac{ECI_p - ECI_0}{||x_p - x_0||_1}$$

where ECI_p is just the ECI of the country after adding some amount of export increment to product p , which is exactly the amount that is able to make ECI change. Also, we can express it in the way of $||x_p - x_0||_1$.

In this way, we can obtain a further sighted greedy algorithm. Also, the number of parts that we would like to separate the budget into also matters. In order to solve this problem, we added a stabilizer on top of the enhanced greedy algorithm, by running the algorithm for different numbers of parts and selecting the portfolio with the largest ECI increment and most complex economic structure.

Besides, it is quite common that there is a surplus for the budget. To deal with the surplus, we just add it to the product which needs the least amount of dollar to make $M_{cp} = 1$, (i.e., the smallest amount of required export increase).

Interpretation:

For the purpose of a clear explanation of the line charts, we try to label all the products in Table 7. Please refer to this table when trying to understand the investment trajectories in the line charts.

Label	Product Names
1	Animals and By-products
2	Vegetables, Fruits and Plants
3	Food and Preparations
4	Energy Drilling and Mining

5	Chemicals
6	Chemical Manufacturing
7	Raw Manufacturing
8	Wood Products
9	Clothing and Accessories
10	Textile
11	Metals
12	Machinery and Construction
13	Transportation
14	Weapons
15	Daily Instruments
16	Precious Stones
17	High-complexity Products
18	Services and Utilities

Table 7: Products Labeling

Below is the economic panel for Canada in 2013. We can see that for different percentages of heuristic total export growth, the ECIs of Canada have different amounts of increments. Overall, 5 and 10 percent export growth result in a similar ECI improvement pattern, which starts from around -0.45 and ends at around 0.38. However, 15 and 20 percent export growth are able to result in obvious ECI improvement trajectories. For a 15 percent growth budget, ECI of Canada is able to end at around 1.27 while for a 20 percent budget, the increment is even more obvious, eventually achieving around 2.20.

For the case of 5 percent export growth, chemical manufacturing, transportation and clothing and accessories account for most of the portfolio. For 10 percent export growth, in addition to the industries that we mentioned before, more weights are put on other industries, such as services and utilities, and high-complexity products. In these two ECI improvement trajectories, we also notice that the largest improvement comes from services and utilities, suggesting that with a low economic improvement anticipation, Canada should focus more on developing the industry of services and utilities. For the case of 15 and 20 percent increment budgets, we realize that the development trajectories are in a similar pattern except that there are a few additional steps when there are more budgets. Different from the previous two cases, the solutions suggest that Canada should invest more on machinery and construction and transportations. This makes sense

because with more budgets, a country should definitely focus more on the development of high-end product spaces. A more detailed numerical representation of the portfolio is shown in Table 8.

Canada ECI Growth Optimization Result

Figure 5: Greedy Based ECI Improvement Results of Canada in 2013 with Different Budgets

Canada (2013)				
Original ECI	-0.45			
Heuristic Export Growth	5%	10%	15%	20%
Vegetables, Fruits and Plants	0.00E+00	3.94E+09	0.00E+00	0.00E+00
Chemicals	1.97E+09	7.88E+09	5.42E+09	2.05E+10
Chemical Manufacturing	8.86E+09	7.88E+09	0.00E+00	6.83E+09
Raw Manufacturing	0.00E+00	0.00E+00	2.17E+10	0.00E+00
Clothing and Accessories	4.92E+09	1.38E+10	0.00E+00	0.00E+00
Textile	2.95E+09	3.94E+09	1.08E+10	1.37E+10
Machinery and Construction	0.00E+00	0.00E+00	6.50E+10	5.46E+10
Transportation	8.86E+09	1.58E+10	4.33E+10	8.19E+10
High-complexity Products	0.00E+00	1.97E+09	5.42E+09	1.37E+10
Services and Utilities	1.97E+09	3.94E+09	1.08E+10	1.37E+10
Increased ECI	0.39	0.37	1.27	2.20

Table 8: Portfolio of Canada in 2013

For further suggestions on Canada's development in the future. We also offer the optimization result of Canada based on export data in 2018. Below is the economic panel for Canada in 2018. We can see that there is a similar pattern for the ECI improvement trajectories, which is that the improvements in 5 and 10 percent export growth are similar, and the ones in 15 and 20 are

similar. But one difference is that the main components that result in ECI improvements are not quite similar. For a 5 percent export growth, the main components include transportation, clothing and accessories, services and utilities, and daily instruments, while for a 10 percent growth, the main components also consist of chemicals, and chemical manufacturing. For situations with higher budgets of investment, like 15 or 20 percent of growth, the portfolios are much more diverse than the previous two cases. In detail, industries like raw manufacturing, machinery and construction, textile are the ones that contribute a lot in ECI increments. A more detailed numerical representation of the portfolio is shown in Table 9.

Canada ECI Growth Optimization Result

Figure 6: Greedy Based ECI Improvement Results of Canada in 2018 with Different Budgets

Canada (2018)				
Original ECI	-0.62

Table 9: Portfolio of Canada in 2018

4.3 Sensitivity Analysis and Contingency Strategy

In the following section our broad aim is to understand how sensitive Canada is to changes in export in various industries. While the Economic Complexity Index has been shown to contain valuable information about the economic strength/capacity of a country, little has been said as to the stability of the measure itself. We seek to uncover the main drivers of stability under a country's ECI score and better understand longer-term projections for ECI growth. Additionally, gaining an intuition on the industries that are bolstering an economy and the industries that offer the greatest return per unit of investment is best done through visualization of industry specific sensitivity. To this end, we have developed two categories of sensitivity analysis.

ECI Sensitivity Graph

Firstly, in order to assess the effect particular industries have on each respective country, we developed ECI Sensitivity graphs. We use shocking methodology to increment or decrement an industry's export level by a certain percentage and recalculate the ECI all else being equal. While freezing the export dynamics of the rest of the world and enacting an instantaneous shock in export for a particular industry and country may not reflect real-life dynamics, what it does offer us is an understanding of a country's level of dependency on an industry in the context of ECI. The shocking is done in small percentage increments in order to smooth out the resulting curve. Additionally, a recurring theme one will see is that for most industries, a breaking point occurs where the ECI either jumps upwards or downwards, creating a hockey stick shape rather than a linear trend. While the inflection point may not be accurate in the context of real life, comparing the various inflection points across industries can give us valuable insight.

The graphs are formulated as follows: There are four ECI Sensitivity graphs. The first two represent data from 2018. The first chart shows positive shocks in which export numbers are shocked upwards per industry. The X-axis is in terms of percentage shock per current dollar value of export. The Y-axis is the recalculated ECI level post-shocking. The second chart follows the same format except the X-axis represents negative shocking. In other words, exports for each industry are decremented and the ECI is accordingly recomputed. The final two sensitivity graphs show the same results using 2013 data. Below is an example of an ECI sensitivity graph.

Example 2018 (Incremental ECI Sensitivity)

SDV sensitivity

Secondly, we analyze the sensitivity of the SDV to changes in export levels. The goal is to understand how export level changes for a particular industry can affect the marginal opportunity gain for other industries. We will be using specifically High Complexity Products and Food and Preparations as our base industries. We will be increasing or decreasing the absolute export level in both of these industries and observing the effects on the SDV.

When the opportunity gain of an industry is negative, the SDV sensitivity approximates how an over-development of the industry jeopardizes the economic structure of a country. When the opportunity gain of the industry is zero, the SDV sensitivity determines whether the further development of the industry shapes the country with a better economic structure and predicts how the SDV would change accordingly. Specifically, as we reduce the export of such an industry to 25%-50% of its original value, a few other industries originally with negative opportunity gain could likely become profitable.

Similar to the ECI sensitivity graphs above, we will be shocking the export of High Complexity Products and Food and Preparations in small percentage increments. A new SDV, represented by a new column in the charts, is recorded only when a certain level of shock changes the structure of the SDV. In effect we are incrementing or decrementing export levels of two industries until the marginal opportunity gain of any industry changes in category (positive, negative, or neutral). Below is an example of a SDV Sensitivity chart with Positive Shocking. Industries with positive marginal opportunity gain are colored blue, neutral is colored white and negative is colored red.

Example High-complexity Products 2018 (Incremental SDV Sensitivity)

Contingency Plan

The Contingency Plan aims to present a set of solutions with respect to upheavals in different industries. Instead of compensating for the declining production directly, the best strategy is to develop those incipiently profitable industries. In this manner, we can derive the contingency strategy for countries to deal with possible abrupt declines of crucial industries. In some cases, the SDV remains unchanged even when a zero-opportunity-gain industry declines to its 20% in terms of export. We can then conclude the industry is not indispensable to the country. As a clarification, the three consecutive N/As means that the country doesn't even need to respond to a collapse in the industry. Countries tend to have distinct solutions to the up and down of the same industry. To create the contingency strategy table we decrease the export level for each industry in the country's current production space by 60% respectively. The three highest ranking industries in the new SDV are then returned.

Example Contingency Strategy 2018

4.3 Sensitivity Analysis Results and Interpretation

Below is Canada's 2018 ECI Sensitivity Charts. Firstly in the positive chart, we notice immediately that increases in High Complexity Product, Transportation, and Machinery lead to an uptrend in ECI. High Complexity Products offer the best ECI growth per unit of export increase. All other industries tend to not greatly affect the ECI level making it fairly clear which industries to pursue.

Next we consider Canada's 2018 Negative Shock chart. We see that Canada's ECI is slightly sensitive to drawdowns in Weapons and Raw Manufacturing. More interestingly we see that large decreases in High Complexity Products and Energy, Drilling, and Mining seem to greatly increase the ECI score. These industries are two very important industries for Canada's economy and thus the results that are reflected in the chart may be suggesting that there is another industry that could be very beneficial for Canada that is far in proximity from High Complexity Products and the Energy industry.

Canada (Postive Shocking)

Canada 2018 (Incremental ECI Sensitivity)

Canada (Negative Shocking)

Canada 2018 (Decremental ECI Sensitivity)

Next we consider the 2013 ECI Sensitivity graphs. We see that in the positive shocking case, the landscape of ECI sensitivity has not altered significantly over the five year period. High complexity products seem to offer the best ECI growth prospects. Transportation and Machinery do not affect ECI levels as positively as in 2018.

In the 2013 negative shocking case, we see that again the US is very sensitive to drawdowns in High Complexity Products and Energy, Drilling, and Mining.

Canada (Postive Shocking)

Canada 2013 (Incremental ECI Sensitivity)

Canada (Negative Shocking)

Canada 2013 (Decremental ECI Sensitivity)

Below we see the SDV sensitivity charts for High Complexity Products. We see that increasing the export of High Complexity Products opens up many positive opportunity gain industries for Canada to move into. In fact after about a 40% increase no industries within the SDV have negative opportunity gain.

In the negative High Complexity Product SDV chart, we see that as we decrease the export of High Complexity Products, the exact opposite happens. The number of industries with positive

opportunity gain shrink suggesting that the opportunities available to Canada are highly dependent on its High Complexity Product footprint.

Concerning Food and Preparations, Canada seems to be mostly insensitive to this industry suggesting that this is not an important industry in terms of the stability of its SDV.

Canada Contingency Strategy 2018

Based on Canada's RID for 2021, we note that the contingency strategy recommended by our algorithm in 2018 is mirrored by Canada's development strategy over the course of the pandemic. As such, it supports the reasoning behind Canada's increase in GDP between 2019 and 2021.

5. Macro-level Predictions

5.1 Structural Optimality Index

Indeed, such choice of prioritization has proven to be a significant factor in deciding the economic outcomes of countries. In order to quantitatively evaluate how effective our development strategies are and how deviations from the suggested developmental path will lead to suboptimal growth results, we define the measure – Structural Optimality Index (SOI) – on a country level as the Adjusted R-Square obtained from regressing the country's realized industry development over the suggested development strategy. Both strategies are quantified in nature, with the realized development represented by export increase in every major industry group and the suggested development strategy represented by the opportunity gains of developing the corresponding industry groups as calculated in previous sections. The adjusted R-square from the regression thus provides us with a quantified measure of how the development path adopted by the country has fitted with/differed from calculations on a complexity level.

After obtaining this measure for all countries in our database, we further regress countries' five-year economic growth, which is defined as the percent increase in GDP (USD), over their SOI. Figure 6 illustrates the regression output, which shows a strong positive correlation between countries' SOI and their five-year GDP growth, significant at the 1% level and achieving an adjusted R^2 of 4.5%. In other words, the more a country develops as suggested by calculations on a complexity level, the better economic outcomes it achieves.

Table 18: OLS Regression Results	
Dep. Variable: GDP	F-Statistic: 5.963

R²: 0.054	Prob (F-Stat): 0.0163
Adj R²: 0.045	No. Observations: 106

Figure 2: Regression of Five-year GDP Growth over SOI

5.2 SOI of Canada and Its Implications

Canada for instance, has a high level of structural optimality as compared with its developed peers. As the regression in Figure 7 suggests (the orange curve represents export increase and the blue curve stands for opportunity gain of the corresponding industry), Canada demonstrates an average level of correlation with the suggested developmental path, having an adjusted R-square of around 19.5%. Canada ranks in top quartile among all countries in terms of SOI and has made a low rate of economic progress below its developed peers from 2013 to 2018 with a 5-year GDP growth rate of 14.4%, which is consistent with the regression result in Figure 6. This is in direct contrast to other developed economies such as Japan, where there is low SOI of around -5.7% and a corresponding GDP growth of 9.05% from 2013 to 2018, making it a much slower developing economy during the period. In sum, Canada's mixed economic progress from 2013 to 2018 can be at least partially explained by a development strategy that demonstrates a decent, but not perfect, level of matches with our suggested developmental path. In specific, Canada invested heavily in the Transportation industry, while it should have focused more on more complex industry groups such as Energy Drilling and Mining. That being said, it stayed fairly in line with our expectations in the chemicals and textiles industry.

Figure 7: SOI of Canada (2013 - 2018)

In 2021, Canada ranks in the second quartile among all countries in terms of SOI and obtains an average 3-year GDP growth rate of 5.15 % between 2019 and 2021. Progress is slow on a global scale during this period, but Canada demonstrates a greater ability to adjust to negative economic shocks by improving SOI and increasing GDP growth.

Figure 8: SOI of Canada (2019 - 2021)

6. Concluding Remarks

In conclusion, Canada has demonstrated a moderate level of economic growth in terms of annual GDP increase during the period from 2013 to 2018, concurrent with a decrease in economic complexity as compared with other major developed economies. In 2021, the economic effects of the COVID-19 pandemic can be seen in Canada's regression in terms of economic complexity despite a considerable increase in GDP.

The lack of progress during the period, we believe, can be partially explained through analysis of the economic and product complexity structure of Canada on the industry group level. The product classification system we adopt allows us to measure the realized industry development for various industry groups and to observe that Canada consistently relied on developing the Transportation industry during the period, while its developed counterparts and emerging

economies around the globe have adopted much more complex and progressive paths. In 2021, the mixed progress is a result of global demand for basic, low-complexity products, which Canada positions itself to meet. As such, its ECI decreases, but its GDP increases at a faster rate, in average, than its developed counterparts.

Based on our analysis of the opportunity gain and a sensitivity analysis of major industry groups, Canada can further its gains by prioritizing High Complexity Products, Transportation, and Machinery and Construction. We further note that Canada has a slightly mismatched development strategy that indicates a moderately high (compared to other developed countries) level of structural optimality on the complexity level, having an adjusted R-square of around 19.5%. Since a significant positive correlation exists between five-year GDP growth and the structural optimality index of an economy as we define and calculate, Canada, however, still has a suboptimal growth experience as compared with fast-growing economies both on a regional scale and on a global scale, and has the potential to further its economic gains through industrial structure optimization as suggested in the paper.
