1. What are three examples of research questions that these analyses are designed to answer?

2. What data are required for these analyses? What are right censored data?

3. Are these methods more suitable for one research design (case-control or cohort) than another?

4. Are there special interpretations or considerations that are required when one applies these analyses to data from a case-control design as compared to a cohort design?

5. How do you decide which model to use?

6. What assumptions need to be made in order to interpret the output estimates for the exposure of interest?
